Abstract: This article presents an efficient approach for solving economic load dispatch (ELD) problems in different test power systems using a novel seeker optimization algorithm (SOA) In the SOA, the act of human searching capability and understanding are exploited for the purpose of optimization. In this algorithm, the search direction is based on empirical gradient by evaluating the response to the position changes and the step length is based on uncertainty reasoning by using a simple fuzzy rule. In this paper, four test systems of the ELD problems are solved by adopting the SOA. A comparison of obtained simulation results by adopting the SOA is carried out with those published in the recent literatures. It is revealed from comparison that the optimization efficacy of the SOA over the prevailing optimization techniques for the solution of the multimodal, non-differentiable, highly non-linear, and constrained ELD problems is promising.

Keywords: Economic load dispatch; multiple fuel options; seeker optimization algorithm; transmission loss; valve point loading

1. Introduction

The prime objective of the ELD problem is to minimize the total generation cost in power system (with an aim to deliver power to the end user at minimal cost) for a given load demand with due regard to the system equality and inequality constraints [1]. To date, various investigations on ELD problems have been undertaken as better solutions would result in more saving in the operating cost.

Several classical methods, such as the lambda iteration (LI) method and gradient method have been applied to solve the ELD problems. But unfortunately, these methods are not feasible in practical power systems owing to the non-linear characteristics of the generators and non-smooth cost functions. Consequently, many powerful mathematical optimization techniques that are fast and reliable, such as non-linear programming and dynamic programming have been employed to solve the ELD problems. But due to the non-differential and non-convex characteristics of the cost functions, these methods are also unable to locate the global optima. Among the artificial intelligence methods, Hopfield neural networks [2] have been applied to solve the non-linear ELD problems, but these methods suffer from excessive numerical iterations, resulting in huge computations. Complex constrained ELD problems have been solved by many population-based optimization techniques in recent years. Some of the population-based optimization methods are genetic algorithm (GA) [3], simulated annealing (SA) [4], Tabu search [5], improved fast evolutionary programming (EP) (IFEP) [6], (PSO) [3], ant colony optimization (ACO) [7], particle swarm optimization differential evolution (DE) [8], bacteria foraging with Nelder-Mead (BF-NM) [9], Seeker optimization algorithm (SOA) [12] is essentially a novel population based heuristic Biogeography-based optimization (BBO) [10], a hybrid technique combining DE with BBO (DE/BBO) [11].

Received: August 19th, 2010. Accepted: February 28th, 2011

Search algorithm. It is based on human understanding and searching capability for finding an optimum solution. In the SOA, optimum solution is regarded as one which is searched out by a seeker population. The underlying concept of the SOA is very easy to model and relatively easier than other optimization techniques prevailing in the literature. The highlighting characteristic features of this algorithm are the following:

- a. Search direction and step length are directly used in this algorithm to update the position,
- b. Proportional selection rule is applied for the calculation of the search direction, which can improve the population diversity so as to boost the global search ability and decrease the number of control parameters making it simpler to implement, and
- c. Fuzzy reasoning is used to generate the step length because the uncertain reasoning of human searching could be the best described by natural linguistic variables, and a simple ifelse control rule.

The algorithm is to model the cooperative manner of human being while performing the group dynamics. In view of the aforementioned underlying concepts of the SOA as an optimizer, can this algorithm be exploited for the solution of the ELD problems of different capacities and volumes? Are the results yielded by the SOA comparable to those reported in the recent literatures? Basically, the present work is an attempt to utilize the optimizing capability of the SOA for the solutions of highly constrained ELD problems.

The present work focuses on the performance of the SOA as an optimizing tool in solving different ELD problems. The main contribution of the paper can be summarized as follows:

- Four test cases of the ELD problems are solved with the help of the SOA and the best results obtained are presented in this paper.
- 2. The best results obtained for the test cases considered by adopting the SOA are compared with those published in the recent papers.
- Based on the quality and the improved convergence speed of the solution as obtained and presented in this paper, the applicability of the SOA in solving the practical ELD problems of power systems is proposed.

The rest of the paper is organized as follows. In Section 2, mathematical modeling of the ELD problem is done. In Section 3, an objective function is formulated which requires to be optimized. The SOA is narrated in Section 4. Test cases and simulation results are presented in Section 5 to demonstrate the performance of the algorithm for the ELD problems. Section 6 focuses on conclusions of the present work.

2. Mathematical Modeling of the ELD Problem

A. ELD with Quadratic Cost Function and Transmission Loss

The problem of the ELD is multimodal, non-differentiable and highly non-linear. Mathematically, the problem can be stated as in (1) [1, 6].

$$Min \ F_T(P) = \sum_{i=1}^{NG} F_i(P_i) \quad \$/h; i = 1, \dots, NG$$
 (1)

Subject to.

(i) Real Power Balance Constraint

The power balance operation can be modeled as in (2).

$$\sum_{i=1}^{NG} P_i - P_D - P_L = 0; i = 1, \dots, NG$$
 (2)

The transmission loss (P_L) may be expressed as a quadratic function of generations (using B coefficient matrix) as given in (3).

$$P_L = \sum_{i=1}^{NG} \sum_{j=1}^{NG} P_i B_{ij} P_j + \sum_{i=1}^{NG} B_{0i} P_i + B_{00}; i = 1, \dots, NG, \text{ and } j = 1, \dots, NG$$
(3)

(ii) Generation Capacity Constraints

The generating capacity constraints are written as in (4).

$$P_i^{\min} \le P_i \le P_i^{\max}; i = 1, \dots, NG \tag{4}$$

B. ELD Problem with Valve Point Loading

For a more practical and accurate model of the cost function, multiple valve steam turbines are considered. Total cost of the generating units with valve point loading is given in (5) [6].

$$F_i(P_i) = a_i + b_i P_i + c_i P_i^2 + \left| e_i \times \sin(f_i \times (P_i^{\min} - P_i)) \right| \ \$/h \ ; i = 1, \dots, NG$$
 (5)

It is to be noted here that the fuel cost coefficients e_i and f_i are introduced in (5) to model the valve point loadings.

C. ELD Problem with Valve Point Loading and Multiple Fuel Options

Considering both valve point loading effect and multiple fuels, the cost function [13] is as in (6).

$$F_{i}(P_{i}) = \begin{cases} a_{i1} + b_{i1}P_{i} + c_{i1}P_{i}^{2} + e_{i1} \times \sin(f_{i1} \times (P_{i_{1}}^{\min} - P_{i1})), & for fuel1, P_{i}^{\min} \leq P_{i} \leq P_{i1} \\ a_{i2} + b_{i2}P_{i} + c_{i2}P_{i}^{2} + e_{i2} \times \sin(f_{i2} \times (P_{i_{2}}^{\min} - P_{i2})), & for fuel2, P_{i1} < P_{i} \leq P_{i2} \\ \vdots & \vdots & \vdots \\ a_{ik} + b_{ik}P_{i} + c_{ik}P_{i}^{2} + e_{ik} \times \sin(f_{ik} \times (P_{i_{k}}^{\min} - P_{ik})), & for fuel k, P_{i_{k-1}} < P_{i} \leq P_{i_{1}}^{\max} \end{cases}$$

$$(6)$$

3. Formulation of The Objective Function

The objective function (OF()) is designed as in (7) that requires to be minimized.

$$OF() = \sum_{i=1}^{NG} F_i(P_i) + 100 \times P_L + 1000 \times abs \left(\sum_{i=1}^{NG} P_i - P_D - P_L \right)$$
 (7)

The weighing factors are selected to make the corresponding terms competitive during the process of optimization. The unit of each weighing factor involved in (7) is \$/MWh.

4. Seeker Optimization Algoritm and Its Application to the ELD Problem

A. Seeker Optimization Algorithm

The SOA [12] is a population-based heuristic search algorithm. It regards the optimization process as an optimal solution obtained by a seeker population. Each individual of this population is called a seeker. The total population is randomly categorized into three subpopulations. These subpopulations search over several different domains of the search space. All the seekers in the same subpopulation constitute a neighborhood. This neighborhood represents the social component for the social sharing of information.

B. Steps of Seeker Optimization Algorithm

In the SOA, a search direction $d_{ij}(t)$ and a step length $\alpha_{ij}(t)$ are computed separately for each ith seeker on each jth variable at each time step t, where $\alpha_{ij}(t) \ge 0$ and

 $d_{ij}(t) \in \{-1, 0, 1\}$. Here, i represents the population number and j represents the optimizing variable number.

a) Calculation of the search direction, $d_{ij}(t)$: It is the natural tendency of the swarms to reciprocate in a cooperative manner while executing their needs and goals. Normally, there are two extreme types of cooperative behavior prevailing in swarm dynamics. One, egotistic, is entirely pro-self and another, altruistic, is entirely pro-group [14]. Every seeker, as a single sophisticated agent, is uniformly egotistic

[14]. He believes that he should go toward his historical best position according to his own judgment. This attitude of ith seeker may be modeled by an empirical direction vector $\vec{d}_{i, ego}$ (t) as shown in (8).

$$\vec{d}_{i, ego}(t) = sign(\vec{p}_{i, hest}(t) - \vec{x}_{i}(t))$$
(8)

In (8), sign (\cdot) is a signum function on each variable of the input vector. On the other hand, in altruistic behavior, seekers want to communicate with each other, cooperate explicitly, and adjust their behaviors in response to the other seeker in the same neighborhood region for achieving the desired goal. That means the seekers exhibit entirely pro-group behavior. The population then exhibits a self-organized aggregation behavior of which the positive feedback usually takes the form of attraction toward a given signal source. Two optional altruistic directions may be modeled as in (9)-(10).

$$\vec{d}_{i, alt 1}(t) = sign(\vec{g}_{hest}(t) - \vec{x}_i(t))$$
(9)

$$\vec{d}_{i, alt 2}(t) = sign(\vec{l}_{best}(t) - \vec{x}_i(t))$$

$$\tag{10}$$

In (9)-(10), $\vec{g}_{best}(t)$ represents neighbors' historical best position, $\vec{l}_{best}(t)$ means neighbors' current best position.

Moreover, seekers enjoy the properties of pro-activeness; seekers do not simply act in response to their environment; they are able to exhibit goal-directed behavior. In addition, the future behavior can be predicted and guided by the past behavior. As a result, the seeker may be pro-active to change his search direction and exhibit goal-directed behavior according to his past behavior. Hence, each seeker is associated with an empirical direction called as pro-activeness direction as given in (11).

$$\overrightarrow{d}_{i, pro}(t) = sign(\overrightarrow{x_i}(t_1) - \overrightarrow{x_i}(t_2))$$
(11)

In (11), $t_1, t_2 \in \{t, t-1, t-2\}$ and it is assumed that $\overrightarrow{x_i}(t_1)$ is better than $\overrightarrow{x_i}(t_2)$. Aforementioned four empirical directions as presented in (9)-(11) direct human being to take a rational decision in his search direction.

If the jth variable of the ith seeker goes towards the positive direction of the coordinate axis, $d_{ij}(t)$ is taken as +1. If the jth variable of the ith seeker goes towards the negative direction of the coordinate axis, $d_{ij}(t)$ is assumed as -1. The value of $d_{ij}(t)$ is assumed as

0 if the ith seeker stays at the current position. Every variable j of $\vec{d}_i(t)$ is selected by applying the following proportional selection rule (shown in Figure 1) as stated in (12).

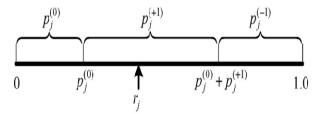

Figure 1. The proportional selection rule of search directions

$$d_{ij} = \begin{cases} 0, & \text{if } r_j \le p_j^{(0)} \\ +1, & \text{if } p_j^{(0)} \le r_j \le p_j^{(0)} + p_j^{(+1)} \\ -1, & \text{if } p_j^{(0)} + p_j^{(+1)} < r_j \le 1 \end{cases}$$
(12)

In (12), r_j is a uniform random number in [0, 1], $p_j^{(m)}$ $(m \in \{0, +1 -1\})$ is the percent of the numbers of "m" from the set $\{d_{ij,ego}, d_{ij,alt1}, d_{ij,alt2}, d_{ij,pro}\}$ on each variable j of all the four empirical directions, i.e. $p_j^{(m)} = (\text{the number of } m) / 4$.

b) Calculation of the step length, $\alpha_{ij}(t)$: From the view point of human searching behavior, it is understood that one may find the near-optimal solutions in a narrower neighborhood of the point with lower fitness value and on the other hand, in a wider neighborhood of the point with higher fitness value.

A fuzzy system may be an ideal choice to represent the understanding and linguistic behavioral pattern of human searching tendency.

Different optimization problems often have different ranges of fitness values. To design a fuzzy system to be applicable to a wide range of optimization problems, the fitness values of all the seekers are sorted in descending manner (for minimization problem) / in ascending manner (for maximization problem) and turned into the sequence numbers from 1 to S as the inputs of fuzzy reasoning. The linear membership function is used in the conditional part since the universe of discourse is a given set of numbers, i.e. 1, 2,, S. The expression is presented as in (13).

$$\mu_i = \mu_{\text{max}} - \frac{S - I_i}{S - 1} (\mu_{\text{max}} - \mu_{\text{min}})$$
 (13)

In (13), I_i is the sequence number of $\vec{x}_i(t)$ after sorting the fitness values, μ_{max} is the maximum membership degree value which is equal to or a little less than 1.0. Here, the value of μ_{max} is taken as 0.95.

A fuzzy system works on the principle of the control rule as "If {the conditional part}, then {the action part}. Bell membership function $\mu(x) = e^{-x^2/2\delta^2}$ (shown in Figure 2) is well utilized in the literature to represent the action part. For the convenience, one variable is considered. Thus, the membership degree values of the input variables beyond $[-3\delta, +3\delta]$ are less than $0.0111(\mu(\pm 3\delta) = 0.0111)$, and the elements beyond $[-3\delta, +3\delta]$ in the universe of discourse can be neglected for a linguistic atom [15]. Thus, the minimum value $\mu_{\min} = 0.0111$ is set. Moreover, the parameter, $\vec{\delta}$ of the Bell membership function is determined by (14).

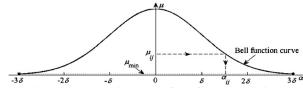

Figure 2. The action part of the fuzzy reasoning.

$$\vec{\delta} = \omega \times abs(\vec{x}_{best} - \vec{x}_{rand}) \tag{14}$$

In (14), the absolute value of the input vector as the corresponding output vector is represented by the symbol $abs(\cdot)$. The parameter ω is used to decrease the step length with increasing time step so as to gradually improve the search precision. In the present experiments, ω is linearly decreased from 0.9 to 0.1 during a run. The \vec{x}_{best} and \vec{x}_{rand} are the best seeker and a randomly selected seeker respectively from the same subpopulation to which the ith seeker belongs. It is to be noted here that \vec{x}_{rand} is different from \vec{x}_{best} and $\vec{\delta}$ is shared by all the seekers in the same subpopulation.

In order to introduce the randomness in each variable and to improve the local search capability, the following equation is introduced to convert μ_i into a vector $\vec{\mu}_i$ with elements as given by (15).

$$\mu_{ij} = RAND \left(\mu_i, 1 \right) \tag{15}$$

In (15), $RAND(\mu_i, 1)$ returns a uniformly random real number within $[\mu_i, 1]$. Equation (16) denotes the action part of the fuzzy reasoning and gives the step length (α_{ij}) for every variable j.

$$\alpha_{ij} = \delta_j \sqrt{-\ln \left(\mu_{ij}\right)} \tag{16}$$

c) Updating of seekers' position: In a population of size S, for each seeker i ($1 \le i \le S$), the position update on each variable j is given by the following equation.

$$x_{ij}(t+1) = x_{ij}(t) + \alpha_{ij}(t) \times d_{ij}(t)$$

$$\tag{17}$$

where $x_{ij}(t+1)$ the position of the jth variable of the ith seeker at time step t+1; $x_{ij}(t)$ the position of the jth variable of the ith seeker at time step t; $\alpha_{ij}(t)$ the step length of the jth variable of the ith seeker at time step t; and the search direction of the jth variable of the ith seeker at time step t.

d) Subpopulations learn from each other: Each subpopulation is searching for the optimal solution using its own information. It hints that the subpopulation may trap into local optima yielding a premature

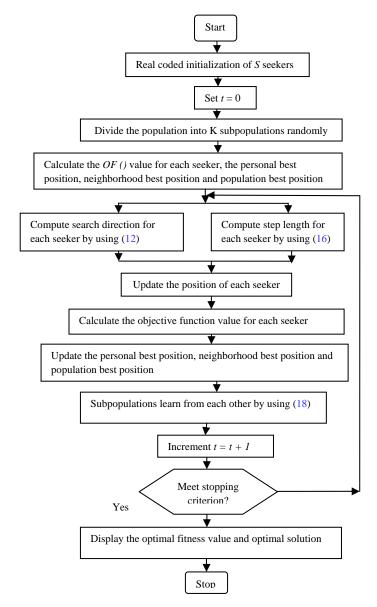

Figure 3. Flowchart of the seeker optimization

convergence. Subpopulations must learn from each other about the optimum information so far they have acquired in their respective domain. Thus, the position of the worst seeker of each subpopulation is combined with the best one in each of the other subpopulations using the following binomial crossover operator as expressed in (18).

$$x_{k_{n}j,worst} = \begin{cases} x_{lj,best}, & \text{if } rand_{j} \leq 0.5 \\ x_{k_{n}j,worst}, & \text{else} \end{cases}$$

$$(18)$$

In (18), $rand_j$ is a uniformly random real number within [0, 1], $x_{k_n j, worst}$ is denoted as the jth variable of the nth worst position in the kth subpopulation, $x_{li \ best}$ is the jth variable of the

best position in the lth subpopulation. Here, n, k, l = 1, 2,, K-1 and $k \ne l$. In order to increase the diversity in the population, good information acquired by each subpopulation is shared among the subpopulations. The flowchart of the algorithm is depicted in Figure 3.

Step 1	Initialization: Read input data, set number of run counter, read cost curves of
	machines and B coefficients, set maximum population number, set lower and
	upper limits of each generator output, read SOA parameters, set termination
	criteria (i.e. maximum iteration cycles).
Step 2	Initialize the positions of the seekers in the search space randomly and uniformly.
Step 3	Set the time step $t = 0$
Step 4	Compute the objective function of the initial positions. The initial historical best
	position among the population is achieved. Set the personal historical best
	position of each seeker to his current position.
Step 5	Let $t = t + 1$.
Step 6	Select the neighbor of each seeker.
Step 7	Determine the search direction and step length for each seeker, and update his
	position
Step 8	Update the position of each seeker.
Step 9	Compute the objective function for each seeker.
Step 10	Update the historical best position among the population and historical best
	position of each seeker.
Step 11	Subpopulations learn from each other.
Step 12	Repeat from Step 5 till the end of the maximum iteration cycles/stopping criterion.
Step 13	Determine the best string corresponding to optimum objective function value.
Step 14	Determine the optimal generation string corresponding to the grand optimum
	objective function value.

Figure 4. Implementation steps of the SOA algorithm for the ELD problems

B. Implementation of SOA for ELD Problem

The steps of the SOA, as implemented for the solution of the ELD problem of this work, are shown in Figure 4.

5. Test Cases and Solution Results

SOA has been applied to solve the ELD problems in four different test cases for investigating its optimization capability. The software has been written in MATLAB-7.3 language and executed on a 3.0-GHz Pentium IV personal computer with 512-MB RAM.

A. Description of the Test Cases

The following four test cases are considered in this work. In the different test cases, while comparing the costs obtained by the algorithms with that obtained by the SOA, the numbers within the {...} denote the minimum values of the total generation costs in \$/h as reported in the referred literatures [...]. The values of the total generation cost are presented in the descending order.

a) Test case 1: 20-generating units without valve point loading: A system with 20 generators is taken as the test case 1. The system input data are available in [3, 16]. The valve point loading effect is not considered for this case but transmission loss is considered. For this test case load demand is 2500 MW. The best generation costs reported for the algorithms in the literature like BBO {62456.77926} [10], Lambda iteration (LI) {62456.6391} [2], Hopfield model (HM) {62456.6341} [2], and chaotic and Gaussian PSO (PSO-CG) {59804.0500} [16] are compared with the SOA-based best generation cost {59421}. The

best solutions of the generation schedules, the generation costs etc as obtained from 50 trial runs of the SOA and other afore-mentioned algorithms are presented in Table 1. The convergence profile of the cost function is depicted in Figure 5.

b) Test case 2: 38-generating units without valve point loading: A system with 38 generators is taken as the test case 2. Fuel cost characteristics are quadratic. Transmission loss is considered. The input data of the system are taken from [17]. The load demand is 6000 MW. The best generation cost {9.0012e+06} obtained by using the SOA has been compared with those by using simple PSO (SPSO) {9543984.777} [18], PSO with Crazy (PSO-Crazy) {9520024.601} [18], New PSO {9516448.312} [18], PSO with time varying acceleration coefficient (PSO-TVAC) {9500448.307} [18], BBO {9417633.637644} [10], and DE/BBO {9417235.78639} [11]. The best solutions of the generation schedules and the generation costs etc as obtained from 100 trial runs of the different algorithms are shown in Table 2. The convergence profile of the cost function is depicted in Figure 6.

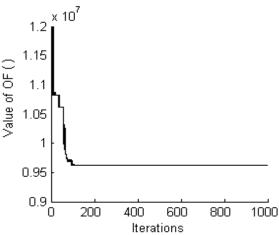

Figure 6. Convergence profile of the total generation cost for 38-generating units

c) Test case 3: 40-generating units with valve point loading: A system with 40 generators with valve point loadings and transmission loss is considered as the test case 3. The input data are given in [6]. The load demand is 10500 MW. The best generation cost{113120}obtained by the SOA is compared to those obtained by using IFEP {122624.3500} [6], hybrid EP and sequential quadratic programming (SQP) (EP-SQP) {122324} [19], PSO with local random search (LRS) (PSO-LRS) {122035.7946} [20], DE combination with SQP (DEC-SQP) {121741.9793} [8], new PSO (NPSO) {121704.7391} [20], new PSO with LRS (NPSO-LRS) {121664.4308} [20], combined PSO with real-valued mutation (CBPSO-RVM) {121555.32} [21],

ACO {121532.41} [7], self-organizing hierarchical PSO (SOH-PSO) {121501.14} [22], hybrid GA-pattern search-SQP (GA-PS-SQP) {121458.14} [19], quantum PSO (QPSO) {121448.21} [23], BBO {121426.953} [10], BF-NM {121423.63792} [9], DE/BBO {121420.8948} [11], real-coded GA (RCGA) {121418.5425} [24], improved coordinated aggregation-based PSO (ICA-PSO) {121413.20} [25], and PSO with both chaotic-sequence and crossover (CCPSO) {121403.5362} [26]. The best solutions of the generation schedules and the generation costs etc as obtained from 50 trial runs of the different algorithms are presented in Table 3. The convergence profile of the cost function is depicted in Figure 7.

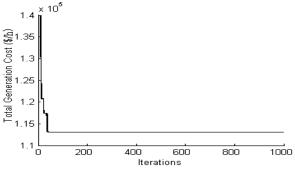

Figure 7. Convergence profile of the total generation cost for 40-generating units

Table 3. Best results for 40-generating units with P_D=10500 MW

d) Test case 4: 10-generating units with valve point loading and multiple fuel options: A system comprising of 10 thermal units with valve point loading and multiple fuels option is considered as the test case 4. The input data are taken from [13]. The load demand is 2700 MW. Transmission loss is not considered in this case. The best generation cost {564.7591} obtained by the SOA is compared to those obtained by the combined improved GA with multiplier updating (MU) (IGA-MU) {627.5178} [13], conventional GA with MU (CGA-MU {624.7193} [13], PSO-LRS {624.2297} [20], NPSO {624.1624} [20], NPSO-LRS {624.1273} [20], RCGA {623.8281} [24], ACO {623.7000} [7], BBO {605.6387} [10] and DE-BBO {605.6230} [11]. The best solutions of the generation schedules and the generation costs etc as obtained from 100 trial runs of the algorithms are shown in Table 4. The convergence profile of the cost function is depicted in Figure 8. The results of interest are bold faced in the respective tables.

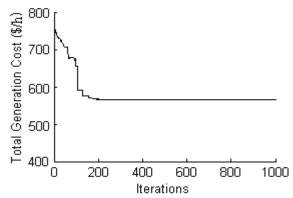

Figure 8. Convergence profile of the total generation cost for 10-generating units

B. Discussions on the Results of the Test Cases

Solution quality: It is noticed from Tables 1-4 that the minimum cost achieved by applying the SOA is the least one as compared to those achieved by the earlier reported algorithms. It is to be recalled here that the highlighting characteristic features of the SOA are (i) the direct usage of search direction and step length to update the position, (ii) the application of proportional selection rule for the calculation of the search direction which can improve the population diversity so as to boost the global search ability and decrease the number of control parameters making it simpler to implement, and (iii) adaptation of fuzzy reasoning to generate the step length because the uncertain reasoning of human searching could be the best described

by natural linguistic variables. These features in the SOA help the algorithm to yield better solutions. It emphasizes on the fact that the SOA offers the best near-optimal solution for the ELD problems considered.

Comparison of the best generation costs: Comparing the minimum costs achieved by the reported algorithms as may be observed from Tables 1-4, the minimum costs achieved by the SOA are the least values given by 59421 \$/h, 9.0012e+06 \$/h, 113120 \$/h, and 564.7591\$/h for the test cases 1-4 respectively. Power mismatches are also the least ones in the SOA as compared to those in others. Hence, it can be concluded that for all the four test cases the optimization performance of the SOA is found to be the best one.

Testing of robustness: The performance of any heuristic search based optimization algorithm is best judged through repetitive trial runs so as to compare the robustness/consistency of the algorithm. For this specific goal, the frequency of convergence to the minimum cost at different ranges of generation cost with fixed load demand is to be recorded. While experimenting the same for the four test cases, it is observed that the frequency of convergence to the minimum generating cost of less than 120×10^3 \$/h is 50 out of 50 independent trial runs for the test case 2, and the same of less than 605.5 \$/h is 100 out of 100 independent trial runs for the test case 4. These frequency figures of attaining the minimum costs with minimum variations are the maximum ones as compared to the other algorithms of the referred literatures for these two test cases. The same for the test cases 1 and 2 are not included in the referred literatures. But, the authors of the present have tested the same with the SOA for the test cases 1 and 2 also and it is noticed that the convergence to the minimum value of the cost function with a minimum variation is achieved with high frequency values. The frequency of converging to the better solution is always higher in the SOA as compared to the other methods. Thus, it may be inferred that the SOA is the most consistent and robust in achieving the lowest cost in all the runs

Computational efficiency: Apart from yielding the minimum cost by the SOA, it may also be noted that the SOA yields the minimum cost at comparatively lesser time of execution of the program. Thus, this approach is also efficient as far as the computational time is concerned.

6. Conclusion

In this article a novel seeker optimization algorithm, based on the act of human searching capability and understanding while performing any task, is applied to the solution of the constrained, multimodal, non-differentiable, and highly non-linear economic load dispatch problem of small, as well as, large size test power systems. It is revealed that the SOA has the ability to converge to a better quality near-optimal solution and possesses better convergence characteristics and robustness than other prevailing techniques reported in the recent literatures. It is also clear from the results obtained by different trials that the SOA is free from the shortcoming of premature convergence exhibited by the other optimization algorithms. The simulation results clearly reveal that the SOA may be used as an excellent optimizer for the solution of practical economic load dispatch problems of power systems.

B. Shaw was born in 1981 at Asansol, Burdwan, West Bengal, India. He received his graduation in electrical engineering and post graduation in electrical power from National Institute of Technology, Bhopal, India and Calcutta University, Kolkata, India, respectively. His research interest is application of soft computing intelligence to various fields of power systems. He will be available at binodshaw2000@gmail.com.

Mr. Shaw is a graduate member of The Institution of Engineers (India).

S. Ghosal is an undergraduate student of electrical engineering of National Institute of Technology, Durgapur, West Bengal, India. His area of research is application of novel evolutionary optimization techniques to restructured power system operation and control along with FACTS and energy storage devices. During the study, he already published one IEEE and one NPSC conference paper in 2010 along with research groups.

V. Mukherjee was born in 1970 at Raina, Burdwan, West Bengal, India. He received his graduation in electrical engineering and post graduation in power system from B.E. College, Shibpur, Howrah, India and B.E. College (Deemed University), Shibpur, Howrah, India, respectively. He received his Ph.D. degree from NIT, Durgapur, India. Presently, he is an assistant professor in the department of electrical engineering, Indian School of Mines, Dhanbad, Jharkhand, India. His research interest is application of soft computing intelligence to various fields of power systems He will be

available at vivek agamani@yahoo.com.

Dr. Mukherjee is a member of The Institution of Engineers (India).

S. P. Ghoshal received B.Sc, B. Tech degrees in 1973 and 1977, respectively, from Calcutta University, India. He received M. Tech degree from IIT (Kharagpur) in 1979. He received Ph.D. degree from Jadavpur University in 1992. Presently, he is acting as professor of electrical engineering department of National Institute of Technology, Durgapur, West Bengal, India. His research interest is application of soft computing intelligence to various fields of power systems and antenna. He will be available at spghoshalnitdgp@gmail.com.

Prof. Ghoshal is member of IEEE and fellow of The Institution of Engineers (India).
