The next major fossil hominid discovery occurred in northeast Africa in 1974. Donald Johanson of the International Afar Research Expedition found almost 40% of the skeleton of "Lucy," perhaps the most famous fossil hominid. Discovered in Hadar, Ethiopia, Lucy was a young female adult hominid. As most fossil hominid discoveries until that point consisted of fragmented bones, individual teeth, or scattered, almost random remains and only occasionally a complete skull, the fact that Lucy was an almost complete skeleton, of a single individual, made her a celebrity overnight. The Lucy skeleton contains fragments of arm bones, ribs, vertebrae, a partial pelvis, one femur, partial lower leg bones, a fragmented skull, and a mandible complete with teeth. When no duplicate bones were found, Johanson concluded they were from a single individual, making Lucy an incredible discovery. After analyzing the remains, he recognized that Lucy had been bipedal and that, although her brain was relatively small, her whole body was proportionally small. She would have stood about 3 feet tall and had a brain size around only 400 ml. This brain size was well within the ape range. This was significant because Lucy was found to be about 3.2 million years old, over half a million years older than *A. africanus* and *A. boisei.* Lucy had a smaller, more ape-like brain than *A. africanus* and *A. boisei,* but she had a hominid-like postcranial skeleton that walked upright and bore many similarities to modern humans. As a result, she proved that bipedality had existed in human precursors far earlier than had been thought and, more importantly, that bipedality arose before an enlarged brain size. This officially disproved Darwin's theory that an enlarged brain size had predated bipedality.

The next task for Johanson was to classify Lucy. Together with Tim White, the two began to study and analyze fossils from Hadar and Laetoli that coincided with the same period in history, from about 3 million years ago and older. The Hadar fossils included Lucy and several other fossil hominids, such as the "First Family" found at a different site the year after Lucy. There, the remains of 13 individuals were discovered, including men, women, and juveniles. From the Laetoli site in Tanzania came the famous "Laetoli footprints," discovered by Mary Leakey, and also numerous hominid fossils that dated back to roughly the same time as those found at Hadar. With the Lucy skeleton providing the evidence that bipedality was possible over 3 million years ago in Hadar, Ethiopia, and the Laetoli footprints demonstrating that it definitely occurred in Tanzania 3.7 million years ago, the two pieces of the puzzle needed only to be brought together. White's casts of the Laetoli fossils were compared with Johanson's fossils from Hadar, and the two men created many influential and, as always, controversial theories. Their interpretation of the fossil evidence led them to conclude that the Hadar hominids represented neither apes nor any known hominid species. These hominids, along with the Laetoli specimens of the same age, represented a single hominid species that was yet unidentified. The unique characteristics of the species included full bipedality, arms longer (proportionally to their legs) than in modern humans, a small brain, sexual dimorphism, and dental anatomy somewhat intermediate between apes and humans (with some exclusive characteristics). Because no stone tools were recovered at any of the sites and their brain size was very small, Johanson and White recognized that these early hominids did not use stone tools. They classified these hominids as *Australopithecus afarensis,* the last common ancestor between humans and chimpanzees that existed from 3.9 million years ago until about 3 million years ago. One problem that this exposed was why, if stone tools were not used for another million years, did bipedality exist if the adaptation of bipedality was to free the hands for tool use?

Recent Interpretations

By the 1980s, Africa had become generally accepted as the birthplace of human origins because of the overwhelming amount of fossil hominid evidence that had been found there. The only dilemma was that, although the previous decades had brought forth an unprecedented amount of fossil evidence for the divergence between apes and early hominids, no link had been found in Africa between the primitive *Homo* species, such as *H. habilis,* and the later, more modern *Homo* species such as *H. neanderthalensis* and *H. sapiens*. The only evidence of this link that existed at that time was that of *Homo erectus*. Many held that Dubois' *H. erectus* from East Java, Indonesia, in Asia, was the missing link, but no specimen from that period, about 1.8 to 1 million years ago, had been found in Africa. That was until 1984, when a team led by Richard Leakey discovered a hominid skeleton even more complete than that of the Lucy skeleton. Discovered near the western shore of Lake Turkana in Kenya, it became known as the "Turkana boy." The skeleton was of a young male that Leakey and White determined had been about 12 years old when it died, although some speculate it could have been as young as 9 years old. The overall height of the individual was 5 feet 4 inches, which many estimate would have been about 6 feet at adulthood. The Turkana boy was the first evidence of an essentially fully human anatomy. Only slight skeletal variations exist between *Homo erectus* and *Homo sapiens*. These variations include a narrower pelvis in *H. erectus,* increasing its ability to run, longer arms than in modern humans, and an upwardly narrowing chest, similar to but not to the extent of Lucy. This shape of the chest put the shoulders of *H. erectus* in a position adapted more for tree-dwelling than balanced, bipedal walking. Its running ability suggested that it was a hunter, not a scavenger as many believed *H. habilis* had been. The brain capacity of the Turkana boy was about 880 ml and estimated to have been about 910 ml as an adult. Although the brain was only slightly smaller than in modern humans, the skull structure showed many ape-like characteristics, such as pronounced eyebrow ridges, the lack of a prominent chin, and a low forehead. Richard Leakey quickly classified the fossil hominid as *Homo erectus,* an African example of the species originally found in Asia by Dubois. He was convinced that the increased brain capacity, similar to a modern infant, was evidence of an ability to make tools, which were found in similar strata. The brain and vertebrae were, however, not large enough to convince Leakey that communication would have been possible to the extent that it is in modern humans today. Various discoveries in the following years led to a debate about whether the African *H. erectus* species should be classified as separate from the Asian species and renamed *H. ergaster.* This is still debated today, although most classify the African species with the Asian species, all as *H. erectus*. The overall significance of the Turkana boy was that it showed an early *Homo* species had indeed become fully human, anatomically, in Africa.

Since the 1980s, hominid fossils have been found in Africa, Asia, Europe, and America. With each new discovery, we learn more about our human history and our evolution. Every new piece of evidence holds the ability to alter what is thought to be true. Therefore every theory about human evolution can, and does, evolve. And theories will continue to evolve, just as humans and every other species on Earth continue to evolve. For example, a hominid discovery in Chad in 2001 of a *Sahelanthropus tchadensis* was dated to be about 7 million years old. Yet this hominid form had been bipedal, demonstrating an even greater antiquity for bipedality in hominids. Another discovery, reported in 2006, of *Homo erectus,* found in Dmanisi on the European continent, gave many new insights. These fossils from Dmanisi had brain capacities similar to *H. habilis* but were determined to be *H. erectus,* based on their cranial morphology. If this was a *H. erectus,* it meant that humans may have left Africa for Europe and Asia far earlier than many had theorized.

What is even more important than the idea that the theories of human evolution can evolve is the need to understand that these theories exist only because of the interpretations drawn from the evidence. The Lucy skeleton was an amazing discovery; to be able to show and display an almost complete skeleton of a human from millions of years ago is a great scientific achievement. But more importantly, the information gained from investigators' analysis of the remains has provided an immense amount of information about human history on Earth.

It is now considered a fact that the enlargement of the human brain developed after the ability to walk upright on two legs. This theory is universally accepted because fossil evidence exists where the leg morphology is similar to modern humans but the cranial capacity of the individual is vastly reduced. In Africa, two different hominid species were found at separate sites, several years apart, but because they were found in strata dated to the same era, it is known that more than one hominid species existed at the same time in the past. The amount of knowledge that now exists about human evolution simply through the analysis of some fossilized bones found in the ground is astonishing. Through interpretation of these fossilized bones and stone artifacts, a story emerges of struggle, defiance, adaptation, and triumph. In short, it is the story of human evolution over millions of years.

Evil and Time

The notion of evil intersects with that of time in three main areas: with regard to the thesis of moral relativism, to the question of our moral responsibility for the future, and to the problem of metaphysical evil.

Moral Relativism

According to moral relativists, there are no universal moral values; rather, what is good or evil is relative to social environments, cultures, and the like. An important aspect of this view is that what is good or evil changes over time; morality is thus rather like the rules of a game. For example, the over in the game of cricket was originally four balls long, then was changed to five, and then to today's six; it would be absurd to say today that the result of a match in 1850 should not count because only four balls were played per over. Similarly, say relativists, slavery was not evil in ancient Athens because it was in accordance with the moral system of that time and place; in contrast, it is evil in the modern world because it offends against the moral systems now in place.

This analogy between morality and games is weak, however. In the case of games, there are two systems of values: the rules within each game and the moral system, which includes the notion and status of following those rules. The notion of cheating, for example, is the same in the 19th, 20th, and 21st centuries: It consists in deliberately breaking the rules, whatever they happen to be at the time, usually in order to gain an advantage. The rules may change across the centuries, and thus which actions constitute breaking the rules will be different at different times, but the view of cheating remains the same: It is wrong.

In the case of morality, however, relativists must avoid appealing to a similar two-level structure; if they do, they are distinguishing between a local morality that includes rules about slavery, and so on, and a universal morality that asserts the wrongness of breaking local moral rules. In the case of games, people are justified in expressing disapproval of a 19th-century cricket cheat who bowled six balls in an over, even though that would today be perfectly correct; moreover, if someone were to condemn as a cheat a 19th-century cricketer who bowled only four balls in an over, people should say that they were wrong to make such a judgment. Relativists, however, must not only deny that people are justified in condemning ancient slavery but also must avoid saying that it is wrong to condemn it; to do so would be to make a universal claim and hence would involve self-contradiction. Moreover, if relativists in one culture, such as that of the United Kingdom, say that their compatriots should not judge the behavior of citizens of another culture, such as that of Saudi Arabia, they must surely be committed to saying that people in Saudi Arabia should also not judge the behavior of people in the United Kingdom; they are therefore doing exactly what they said must not be done—imposing on the Saudis their own view of what should be done, their own relativist moral theory.

In an attempt to develop a more sophisticated form of relativism that avoids problems such as this, Bernard Williams has appealed to what he calls a "relativism of distance." He argues that the problem with "vulgar relativism" is that the conclusions it draws are not simply *within* morality but *about* morality; hence he develops an appraisal-relativism, which focuses on the conditions under which individuals can appraise their appraisals in terms of genuineness (using "genuine" in an absolute sense).

The core of this approach is the claim that talk of right and wrong with respect to moral outlook need apply only if a society is sufficiently close to one's own. Williams distinguishes between two types of confrontation with belief systems: real and notional. A real confrontation between a society and another belief system at a given time occurs when it would be possible for the society rationally to adopt the belief system without losing its hold on reality. The confrontation is merely notional if the society could not rationally adopt the belief system; it is too far from its view of the world. Making clear the difference between this and vulgar relativism, Williams stresses that it is not that one society *cannot* judge or interfere with another, but that it would lack any rational basis for doing so.

Put another way, a confrontation is notional between our own moral outlook and another, such as one in the past, in the sense that the other is not a real option for us. We are not in a position to make an assessment or appraisal, because the moral point of view from which such appraisals are made is no longer our moral point of view. The fact that we do not share or no longer hold that point of view makes it impossible for us to make or continue to make such assessments. We have lost or no longer share the concepts and the point of view from which we can make such assessments; we can still understand and learn about the culture, history, and social world of the other moral outlook or moral concepts, and see that in some sense these circumstances warrant or entail the truth of their moral judgments, without sharing their moral outlook or these judgments, in much the same way as a historian can understand and learn about a society or an outlook that he or she does not share. Thus, our own moral concepts, appraisals, and moral judgments get no purchase on the other outlook; we can assess its internal consistency, but we cannot claim that it is incorrect; we must simply leave it unjudged and unappraised.

Williams's approach is reminiscent of Thomas S. Kuhn's account of paradigms in the philosophy of science (and it is interesting to note that Kuhn denied that his was a relativist theory). Two scientific paradigms are incommensurable, for they make different assumptions; use different standards, definitions, and concepts; and use language in different ways. Rational comparison of paradigms is prevented by the fact that one must judge one paradigm from within another; there is no neutral or privileged viewpoint. As with Williams's sophisticated moral relativism, though, this makes no claim about the possibility of one paradigm actually being better (closer to the truth) than another; it merely claims that we can never be in a position to know this.

With respect to many questions, however, in particular with questions of justice, Williams admits that people find it difficult not to treat the confrontation between opposing sets of belief as *real* rather than notional. Also, John McDowell has pointed out that there is an urgent question about the coherence of the relativism of distance: If an outlook conflicts with one's own (a condition of the problem to which relativism is supposed to be a response), how can one coherently combine one's recognition of the conflict and standing by one's own outlook with a disclaimer of any interest in, or even possibility of, making some negative assessment of the other? The fact that going over to the other outlook is not a real option makes no obvious difference to this.

Responsibility for the Future

Is it possible for an action to be evil because of its consequences for future victims? There are various ways in which such a question arises; in one sense, after all, most if not all actions have consequences for future victims, because an action's effects are in the future by definition. The assassin's finger squeezes the trigger shortly before the bullet hits its target and perhaps days before the victim dies, by which time both assassin and victim are, in many ways, different people. The temporal aspect of such examples, however, seems to raise no real extra moral problems. We are here concerned with more straightforward cases in which the effect *significantly* postdates the cause, especially with cases in which the thing or person affected does not yet exist when the action is performed. For example, in the sociopolitical context many kinds of behavior have implications for future generations. Environmental ethicists are concerned with this issue, but the most direct example is raised in the field of political philosophy.

A dilemma is raised for believers in democracy by the existence of political parties whose platforms include the dismantling of the democratic system. If the people of a state vote for such a party, and thus choose to move to a dictatorship, tyranny, theocracy, or the like, what should the committed democrat think? On the one hand, the democratic will of the people has been made clear and should surely be honored, but on the other hand the result goes against the democrat's central principle. One way of resolving the dilemma is to point out that democracy involves the right of the citizens of a state to choose *their own* government, not that of other people. If, for example, one state invades and overthrows the government of its neighbor, it is no excuse to say that the invasion was the result of a democratic referendum or that it was carried out by a democratically elected government. If we are not entitled to take away our neighbors' freedom by invading them, why should we be entitled to take away that of our children or grandchildren by installing a dictatorship? That they are separated from us by time rather than by space surely makes no difference morally.

The main objection to such a position depends upon the view that the future, having not yet come to be, is not real. Future generations, therefore, do not exist, and we cannot have moral responsibilities toward what does not exist. In response, it can be argued that there is an important distinction to be drawn between individuals and classes: Whereas we can have no obligations to a nonexistent and therefore indeterminate individual, we can have obligations toward a class whose members are all in the future, for such a class *can* be determinate. For example, we know exactly which criteria will allow us to determine the members of the class of people born in the year 2027, even though we cannot yet identify any of them, but we have no independent criteria by which to pick out a particular member of that class, even in principle.

Such considerations also affect other moral questions concerning the role of time, such as abortion, contraception, and celibacy. To what extent is the future person who would (or might) have existed a genuine object of our moral concern? Can it be a moral object as an individual, or merely as a member of a class? For example, it might be argued that universal vegetarianism is not clearly desirable even from the point of view of our moral obligations to animals, as the suffering and deaths of the animals killed for food has to be set against the fact that millions of future sheep, cows, pigs, and so on, which would otherwise have been bred for the table, would no longer be needed and would thus lose their chance at any sort of existence. If a short life is better than no life, then it would seem that universal vegetarianism would deprive millions of future animals of their lives and that this would outweigh any good done.

This reasoning, however, makes the assumption that the members of the class of future animals are determinate individuals with moral status. It is true that future animals that would be killed for their flesh can be treated as such, for if we continue to breed animals for food, our actions will create individuals to which harm can be done. If, on the other hand, we decide to stop the breeding process, then no animals (determinate or otherwise) are created by our actions; an animal that is never born is not an animal at all; it does not (and never will) exist in order to suffer harm. The same reasoning is relevant, *mutatis mutandis,* in other areas of practical ethics, such as abortion and euthanasia.

Metaphysical Evil

The notion of metaphysical evil arises primarily in the context of theodicy and involves the fact and effects of contingency, that is, issues such as death and the shortness of life. In fact this usually involves talk of time when what are actually at issue are temporal processes—changes occurring within time. This sort of confusion is most obvious with regard to utterances such as "time is the great healer" or "*tempus edax rerum*" ("time the devourer of things"); strictly speaking, time has no causal powers, either of healing or of destroying, but what we really mean to refer to is the succession of causally related events occurring within time (note, however, that whether time is in fact something in itself rather than merely the relationship between events is one of the main questions dealt with in the metaphysics of time).

In pre–Islamic Arabic thought, time was viewed as the controller of human destinies (usually impersonal), setting the outcomes of our actions rather than the individual actions themselves, and in particular determining the time of our deaths. This role was taken over by God in Islam (though with deep disagreements concerning the degree to which God determines events, especially with regard to the human will).

Systems of thought such as those of Hinduism and Buddhism have responded to aspects of metaphysical evil by developing the notion of reincarnation (or, in Buddhism, rebirth). According to such accounts, it is true that the individual human life span is short and that there is great unfairness in the distribution of goods with which we are born, such as health, intelligence, social status, and so forth; this, however, is placed in the context of an existence that spans many lifetimes, either through the passing of a changeless *atman* from one incarnation to the next, as in Hinduism, or the causal chain of deaths and births, as in Buddhism.

For theologians such as Saint Augustine of Hippo, our existence in time is both symptom and condition of our imperfect nature; God is not in time but rather is eternal, creating time in his creation of the world. This view can be traced to influences on Augustine from the Manichaeism of his early life, before his conversion to Christianity. A similar approach can also be found in Zoroastrianism, though its account is particularly complex, involving two types of time: boundless time and the bounded time of the world as we know it. There was originally only boundless time, but Ahura Mazda created bounded time in order to constrain Ahriman, the evil one, and to enable his ultimate defeat. The notion that time is both a worldly imperfection and the means to the overcoming of that imperfection can be found in much of the later theology of the Abrahamic religions.

Evolution, Chemical

Chemical evolution is the process of the synthesis of biochemically important molecules starting from simple molecular building blocks, such as water (H_2O), nitrogen (N_2), carbon dioxide (CO_2), and hydrogen sulfide (H_2S), under plausible primordial conditions that governed the prebiotic Earth. It describes a process of increasing complexity from simple inorganic compounds toward first simple organic compounds that in turn formed biochemically important structures for a first living system. First life may have started up as a final product of chemical evolution. This event is probably the result of a multitude of processes, most of them not very likely, that led to a proper arrangement and activation of complex molecular building blocks.

Chemical evolution on a timescale is preceded by the formation of elements in stars in consecutive nucleosynthetic processes and by the formation of first simple compounds in space at a later stage. Eventually, interstellar matter aggregated to form the solar system and the terrestrial planets, Earth, Mercury, Venus, and Mars, about 4.6 billion years ago.

Chemical evolution on Earth is a process that probably started later than about 3.8 billion years ago. It is difficult to date the single stages even roughly, as little geological and chemical record remains. During the following millions of years chemical evolution must have led to the origin of life on Earth, as the oldest- known fossil records stem from a period about 3.5 billion years ago.

Chemical evolution is a development that is strongly influenced by the environment of the terrestrial planet, such as composition of the atmosphere, types of radiation, and geology. Any development is determined by the laws of nature and statistics. Therefore, it should be possible to simulate basic chemical processes that occurred several billion years ago. A fundamental problem, however, is the lack of knowledge about the exact environment on planet Earth at that time. Because of the lack of knowledge, the possibility to plausibly reconstruct the process of chemical evolution is very limited.

Not only does the environment affect chemical evolution, but chemical evolution changes the environment. Molecules are formed and altered. There will be a kind of competition between molecules for nutrients. The rate of formation as well the rate of destruction is decisive for an enrichment of certain types of molecules.

Chemical evolutionary processes, in general, should not be limited to Earth but could also proceed on any terrestrial planet because principal chemical laws should be valid throughout the whole universe.

Origin of Elements

Until the beginning of the 19th century, there had been only little knowledge about the abundance and the origin of elements in the universe. The development of spectrochemical analysis in 1860 made it possible to identify elements by their wavelength characteristics of emitted light. By investigating the light of stars and other celestial bodies, for example, nebulae and dust clouds, optical spectroscopy proved the existence of the same chemical elements in the sun and throughout the universe. Hence, there is only one kind of chemistry in the universe.

In the 1950s, after scientists had discovered that hydrogen is the main constituent of the sun, a theory was developed that explained the formation of practically all elements in the core of stars. At extremely high temperatures of at least 10^7 K (kelvin) and extreme pressures, the elements—more precisely the nuclei of the elements—are built up in consecutive thermonuclear fusion processes starting from hydrogen. As a primary process, hydrogen is converted to helium (He) by the combination of four hydrogen nuclei, simple protons, into one helium nucleus. This process, which can take up to some 10 billion years, goes on until practically all hydrogen in the star is exhausted. In secondary processes and at even higher temperatures, He can be converted to heavier elements that in turn can be converted or combine in complex fusion or secondary processes to form all other elements. Uranium is the heaviest element being formed in stars.

Besides hydrogen and He, which amount to 99% of the elements in the universe, carbon, nitrogen, and oxygen are the next most abundant elements. Beyond these elements, abundance decreases somewhat irregularly with increasing atomic weight, with the exception of elements around iron. The relative abundance of elements in the universe is controlled by the rates of thermonuclear fusion and secondary processes of the nuclei in stars. It is probably decisive for further chemosynthetic processes how the relative abundance of elements is at an actual place of chemical evolution.

Once liberated from a star, the generated elements can readily condense and undergo reactions with each other at lower temperatures in space. Accumulation processes of this material will give rise to nebulae with dust and molecular clouds. Dust in the interstellar matter consists mainly of carbon and different oxides. From such a kind of nebular system that began to condense, our solar system started about 5 billion years ago. That means that practically all atoms that built up the solar system originated from former nucleosynthetic processes in other stars.

The Primitive Earth

Formation

About 4.6 billion years ago, the Sun and planets were formed within the protostar disc, which mainly consisted of gas and dust. At that time meteorites also were formed that still preserve some of the original material of the solar system. It is feasible to date meteoric material found on Earth by analyzing the content of specific radioisotopes, for example, potassium or uranium, that suffer radioactive decay. This gives an estimated age of the solar system, and hence the Earth, of about 4.6 billion years.

An immense heat and strong solar winds were emitted from the contracting protostar in the center of the dust disc. These radiations blew away all volatile substances like hydrogen (H_2), He, and N_2 from the inner zone, the terrestrial planet zone. Only dust grains and aggregates of nonvolatile, dense matter were left over in that region. Consecutive collisions and accumulation of these materials finally led to the inner protoplanets. In the case of the earth, accretion led to a metal core of mainly iron, which was surrounded by a mantle and a crust of moderately volatile compounds like oxides that also contained volatiles like H_2O (water). At the end of this accretion process, which took about 100 to 200 million years, the planet Earth presumably was covered by magma oceans due to an enormous release of energy from core formation and radioactive decay of instable isotopes. How and how long the cooling of the earth took place is still discussed.

Environmental Conditions

An accepted model of the primitive atmosphere does not exist because air records are missing and geological records are incomplete. Anyhow, it is decisive for the plausibility of any hypothesis regarding chemical evolution to know which components were the major and minor constituents of the primitive earth's atmosphere.

Because most gases from the original dust cloud were swept away by solar winds during the formation of Earth, there was no or only a thin atmosphere at the beginning. It is assumed that intense volcanic activity led to the degassing of occluded and chemically combined volatiles that formed a secondary atmosphere. Some components like methane (CH_4), N_2, H_2, and ammonia (NH_3) are liberated if meteoric material, assumed to be similar to the material of the primitive earth, is heated to about 1000 K. Hence, these gases could contribute to a primitive, reducing atmosphere. Such an atmosphere is indeed crucial for one major scientific theory about the origin of life, the so-called soup theory. Nevertheless, it is doubtful whether such an atmosphere could persist for a long time. Hydrogen could escape easily from the weak gravitational field of the earth, and NH_3 as well as CH_4 would have been rapidly destroyed by the intense solar ultraviolet radiation.

Today it is supposed that the outgassing from intense volcanic activities provided the compounds for a secondary, only weakly reducing atmosphere consisting of mainly steam and CO_2. These compounds are the major constituents of extant volcanic exhalations, too, and it is reasonable to assume a similar composition for the extant ones as for those on the primitive Earth. Besides, there was no oxygen (O_2) present in the atmosphere at that time, as could be concluded by the abundance of reducing ferrous ions in geological material. Recent studies hint at a higher proportion of H_2 in the primitive atmosphere.

One has to regard possible energy sources for the formation and conversion of first organic molecules as one prerequisite for chemical evolution. On the primitive Earth that was already cooled down, the three main sources of energy were solar irradiation, electric discharges, and energy from geochemical reactions, beside minor contributions from radioactivity, volcanoes, and shock waves as a result of impacts. Solar radiation provided the main source of energy, although the relevant wavelength range for organic synthesis, the ultraviolet (UV) radiation, contributes only a small fraction to the total irradiation. Many simple gaseous molecules like CO_2, carbon monoxide (CO), H_2O, and CH_4 absorb UV radiation only below 190 nanometers, and very simple organic molecules can be generated as well as destroyed by that short-wave UV radiation.

Electric discharges are an efficient source of energy for the production of biomolecules from gas molecules, but it is doubtful whether this source contributed remarkably to the generation of organic substances. Energy and catalytic activation could also be provided by geochemical reactions that could have led to the selective generation and further modification of organic compounds from simple inorganic precursors.

Any just-formed organic compound was immediately endangered by decomposition due to UV radiation or other secondary processes. Only molecules that found a sheltered place or could react to form more resistant molecules could persist for some time.

The Primitive Soup

How life could develop on Earth has been the subject of religious and philosophical discussions for centuries. The first approach to explaining the generation of organic matter scientifically and a proposal for how first life originated on Earth were done independently by Alexander Oparin and J. B. S. Haldane in the 1920s.

Their hypothesis was based on the assumption that Earth's primitive atmosphere had reducing properties and consisted mainly of CH_4, NH_3, H_2, and H_2O. The atmosphere was exposed to various energy sources, for example, lightning, volcanic heat, and solar radiation, leading to the formation of organic compounds. These compounds accumulated in the primitive oceans to form a "hot dilute soup." Because the compounds would remain there for long periods of time, first life would ultimately develop in a spontaneous process of organization.

Today, the primitive soup theory is seriously questioned although it is still strongly propagated. The primitive atmosphere assumed to be reducing, according to the theory, was evidently rather neutral, lacking significant amounts of CH_4 and NH_3. Moreover, these compounds would have suffered rapid decay by photolysis. Furthermore, most organic molecules would not persist for a long time in the postulated primitive soup but would be destroyed quickly so that high concentrations of organic compounds are not likely. Additionally, a spontaneous linkage of many building blocks (monomers) to polymers that exist in extant life cannot happen as easily as proposed, for energetic reasons. Thus, the origin of a living system based on biopolymers is not plausibly explained.

Precursors to Organic Evolution

Since 1953, laboratory scientists **have** attempted to produce all biologically relevant compounds, such as amino acids, nucleobases, and sugars, under prebiotic conditions, thus mimicking the environmental conditions of the primeval Earth. These investigations were motivated by the assumption that the same kinds of biochemical substances as extant ones were the basis for the development of first life.

In 1953, Stanley Miller and his supervisor Harold Urey set up an experiment designed to simulate the atmospheric conditions of the primeval Earth. It was intended to produce possible precursors of chemical evolution. A flask was filled with H_2O and the reducing gases NH_3, CH_4, and H_2. After closing, the flask was heated and exposed to electric discharge for 1 week. The obtained reddish solution proved to be rich in some sort of tar as well as simple amino acids (a total of about 1%) and some small reactive intermediates like hydrogen cyanide (HCN) and formic acid. The energy input into the experiment is comparable to that of about 50 million years ago on the primitive Earth. Experiments using another input of energy like heat and solar radiation generated yields of products that were consistent with the Miller–Urey experiment. Further experiments that simulated the interaction of the primitive atmosphere's gases with lava flows at temperatures of up to 900°C also showed a complex variety of organic molecules. All these experiments support the idea of chemical evolution in a way that the interplay of gaseous carbon, N_2, H_2O, and H_2 and an energy input leads first to the synthesis of reactive intermediates that in turn generate biologically related molecules. Some of the formed intermediates were used in further prebiotic experiments. In such experiments, usually rather high starting concentrations lead to the formation of the nucleobases, from HCN, and mixtures of sugars, synthesized from formaldehyde.

Many critical remarks were addressed to these results. First, experiments in which a mixture of N_2, CO_2, and some H_2O was exposed to electric discharges and heat did not yield amino acids, although such atmospheric conditions seem more realistic today. Besides, peptides (proteins)—as crucial compounds in extant life—could never be built up selectively from amino acids under prebiotic conditions. It is in general not very likely that larger molecules form spontaneously from building blocks in solution. Even if they do form, the sequence will be random and not specific; that is, no two identical copies will occur in billions of possible polymers. Moreover, many of the produced compounds are reactive, especially the nucleobases and sugars, and therefore not stable for many years under prebiotic conditions. Hence, higher concentrations and stability for a longer time as required for organization processes need more complicated constructions for a plausible primeval enrichment.

To summarize, the experiments provide a possible explanation for the formation of building blocks for extant biopolymers. Further organic evolution pathways leading to the specific buildup of biopolymers are highly uncertain and exhibit several principal problems that still need to be solved by scientists.

Theories Involving Minerals

Vital Clays

One major question in the field of chemical evolution is how a replicating system, a system that could generate and transfer information, could have evolved. The modern genetic machinery is much too complicated and was probably preceded by other systems.

Graham Cairns-Smith proposes that clay minerals were the first species that were able to reproduce. Clay minerals, being ubiquitous on the primitive Earth, are composed of many parallel layers that are stacked on each other. Information could be generated by stacking defects during crystallization that produced many identical layers until further modification, that is, occurrence of further mutation. Separation of the layers could spread new forms. Various types of surfaces formed and showed different catalytic activity for organic synthesis. Gradually, more and more complex organic substances were built up that finally started a more sophisticated replicating system replacing the clay replication system in a process termed *genetic takeover.*

Apart from a few controversial experimental investigations that show a conservation of layer structures on crystal growth, there is not much experimental evidence for the hypothesis. However, experimental investigations show the ability of clay minerals to attach organic molecules and to act as catalysts in organic syntheses.

Iron–Sulfur World Theory

Günther Wächtershäuser introduced an alternative hypothesis that suggests a process of chemical evolution in the environment of hydrothermal systems. A geochemical reaction plays the central role, namely, the reaction of the mineral iron sulfide FeS with the gas H_2S that provides the energy (reducing power) for the conversion of inorganic building blocks like CO_2 and N_2 to simple organic molecules. This reaction is driven by the formation of the mineral pyrite, commonly known as fool's gold. Any generated organic material becomes electrostatic when attached to and accumulated at the surface of pyrite. Further reactions at the surface could lead to the development of a surface reaction system and finally a true chemoautotrophic surface metabolism.

Proponents of this hypothesis rejected the idea that a situation like the primitive soup that led to a first heterotrophic organism ever existed on the primitive Earth. Instead, the first organism is supposed to have originated from the postulated surface metabolism.

The hypothesis gains attention because of the importance of iron–sulfur clusters in extant enzymes that convert simple molecules to complex molecules, for example, N_2, H_2, and CO, which also existed on the primitive Earth. Furthermore, one can find a rich fauna around hydrothermal vents (black smokers) at the bottom of the sea where hot fluxes rich in metal ions and sulfur species mix with cold sea H_2O. Similar places presumably existed on the primeval Earth, too. Today, they host several *Archaebacteria,* some of the most ancient living species on Earth, which feed on chemical reactions. Hence, these bacteria may be successors of first living species in that habitat.

First experimental studies did prove the reducing power of the proposed energy source, for example, showing the reduction of N_2 to NH_3. Critics remark that a direct reduction of CO_2 could not be observed in several studies. Moreover, it seems to be very difficult to verify experimentally whether the postulated complex metabolism would operate and how a replicating living system could finally emerge.

Precursors to Chemical Evolution on Earth

Comets, asteroids, and meteorites have always been deliverers of extraterrestrial material to Earth. Especially the primitive Earth was exposed to heavy bombardments, the last intense one 3.8 to 4 billion years ago. These impacts provided large amounts of H_2O and carbon-containing substances probably available for the process of chemical evolution.

Asteroids and their collision fragments, meteorites, stem from the asteroid belt that is situated between the orbits of the planets Mars and Jupiter. Meteorites contain ancient material from the time of the formation of the solar system that resembles the material of the accreting Earth. Beside stony-iron and iron meteorites as two main groups, there are carbonaceous meteorites representing about 3% of the meteoric material on Earth. The carbonaceous meteorites contain substantial amounts of carbon, including small fractions of simple organic molecules such as hydrocarbons, fatty acids, and amino acids. Meteorites of Martian material that were flung into space during impact events on Mars have also been found on Earth.

Comets originate from the outer solar system. Hence, they are rich in volatiles like water ice and simple carbon-containing substances that gathered together with dust grains around 4.6 billion years ago. They contain the oldest, mainly unchanged material within the solar system. It is assumed that comets carried large amounts of H_2O as well as some organic material to the primitive Earth, as simple amino acids could be detected in experimental studies simulating the behavior of comet-like material in space.

Although the impact of larger bodies led rather to a net loss of H_2O and destruction of organic material, certain amounts of organic molecules still arrived on the primitive Earth carried by smaller bodies. It remains uncertain to which extent the extraterrestrial material contributed to the chemical evolution on the primitive Earth.

There are supporters of the idea that germs of life were brought to the primitive Earth by comets or other carriers. This hypothesis lacks evidence, and it just shifts the location but does not provide a plausible explanation for how chemical evolutionary processes proceeded.

Is Chemical Evolution the Pathway to Life?

It is crucial to first determine the driving forces of chemical evolutionary processes. The main parameters are energy and kinetics, which determine whether and how fast reactions can proceed. If there are several parallel reactions that can occur, there will be, under thermodynamic equilibrium conditions, a statistical distribution of the possible products at the end, depending on the relative energy of the products. Thus, it may take time until energetically only less-favored products reach a significant quantity to establish new reaction pathways. Furthermore, any energetically less-favored product tends to convert to another, more stable product. Thus, rather simple and low–molecular-weight compounds (monomers) that are energetically favored will be the main products of reactions under thermodynamic equilibrium conditions.

For the formation of more complex systems, statistically not favored conditions or nonequilibrium conditions are required that favor rather complex and high–molecular-weight compounds (polymers). The latter case is only attainable if a continual energy source is present that can sustain such a nonequilibrium system. High–molecular-weight compounds can form from a complex reaction system either by a series of chance events with almost zero probability or by sequential processes driven by a suitable energy input that keeps the system away from thermodynamic equilibrium. Such nonequilibrium conditions may be essential for the generation of more complex compounds in a reaction system directed by catalytically active substances.

Even if for some reason high–molecular-weight compounds form that contain some kind of inheritable information, there will be still many other factors that have to occur simultaneously to start up a living system. Due to the complexity of life and its emergent property, it is difficult to imagine a process that will inevitably lead to life. The process of chemical evolution toward the origin of life, because it is partly due to nonequilibrium conditions, can be better described as a contingent process. This means that more or less probable processes like pre-organization have to be interpreted as embedded in other independent, external processes whose probability of occurring cannot easily be estimated. So the origin of life as a result of chemical evolution is neither exclusively directed by chance (consequently, unique) nor completely deterministically explainable and inevitable.

Any molecular process cannot be purposive in the sense of ultimately producing life, because molecules are not dead or alive and therefore do not show the complex characteristics of living systems. Likewise there is no indication that natural laws possess a preference that favors the production of chemicals important for biochemistry and ultimately will lead to life.

Is Chemical Evolution a Repetitive Process?

Chemical evolution is a process driven by one or multiple energy sources. A conversion of available inorganic precursors to organic molecules is followed by further steps that produce more complex molecules until, finally, biochemical compounds start up life. Such a development cannot proceed in the presence of O_2, it being harmful to organic molecules. Thus, sites that were exposed to the atmosphere could provide a possible environment only until about 2 billion years ago when the O_2 content in the atmosphere significantly increased. Despite the deterioration of the atmospheric conditions, there probably existed niches devoid of O_2 where chemical evolution still could take place.

A more serious problem was the heavy impact of asteroids or comets on the primitive Earth during the so-called late heavy bombardment around 3.8 billion years ago. At that time, Earth was regularly, in periods of every 10 to 100 million years, sterilized by heavy impacts whose violence could lead to the evaporation of the oceanic water and the melting of the earth's crust down to 1 kilometer. One can imagine that all life having arisen between two such impacts suffered complete extinction, and a new development had to start from the beginning. The picture of production–extinction cycles may describe aptly the situation at that time. As long as the basic environmental conditions of the primitive Earth did not change dramatically for a long time, chemical evolution could repeatedly take place. It is possible that different kinds of biochemical systems developed and disappeared during that rough period and that the last one was chosen by chance as the basis for further evolution.

In addition, such differently distinctive biochemical systems may also have developed simultaneously or successively in different environments as the result of similar chemical evolutionary processes. Nevertheless, ultimately all but one became extinct due to competition or accidents, because all extant life is based on a common biochemistry.

Chemical Evolution in Extraterrestrial Places

In the 16th century, philosopher Giordano Bruno, at the expense of his life, claimed that many inhabited worlds existed. He might have been right, as a simple count of the number of stars in the universe yields an enormous number. Many stars probably have a planetary system, so that there should be a huge number of planets similar to Earth. Taking into account that the same physicochemical laws and principles are valid throughout the whole universe and with the same elements present, chemical evolutionary processes should be possible at many sites in the universe. Even if extraterrestrial biochemical systems different from the terrestrial ones developed, the crucial bioelements carbon, oxygen, nitrogen, and sulfur, as well as H_2O, would have been required to start a chemical evolution.

At this point, one has to distinguish between (a) places of prebiotic synthesis of organic material in general, like dust clouds, meteorites, and comets; and (b) places of prebiotic synthesis that can lead to chemical evolution, such as planets or moons.

Interstellar clouds of dust contain a large variety of simple and reactive organic molecules, such as HCN and formaldehyde. Little is known about the mechanisms that alter the organic precursors, and there is no indication that more complex or even polymeric molecules can form. Nevertheless, the organic compounds in the dust grains will contribute to planetary material if solar systems arise from dust clouds.

Meteorites and comets contain larger and more complex organic molecules than was once thought by scientists. Remains of living systems, however, have not been found in that ancient material, and it is uncertain whether cosmic conditions allow life to arise there.

Terrestrial planets and moons, on the other hand, may have an atmosphere and some liquid solvent at the surface; in other words, there is a true environment for chemical evolutionary processes. Even if extraterrestrial bodies are similar to Earth, chemical evolution may have led to a different outcome. Because extrasolar sites are difficult to access, two prominent examples in our solar system, the planet Mars and Saturn's largest moon Titan, are briefly discussed.

Mars had a planetary history similar to that of Earth. About 3.8 billion years ago, an atmosphere of CO_2 probably caused a greenhouse effect that generated mild conditions with liquid H_2O at the surface. This short period was finished by bombardment from space, leading to the loss of the atmosphere and thus the end of the greenhouse effect. The dropping of temperatures on Mars caused water to freeze, being covered by rock gradually; solid CO_2 was deposited in the polar regions. It is assumed that geothermal processes releasing frozen water and CO_2 from the ground as well as instabilities in the orbit around the sun could have led to repeated short warmer periods. Today, Mars's surface is very cold and exposed to intense UV radiation so that no life is expected to be found there. It is rather probable that some chemical evolutionary process proceeded during the short warm period in Martian history 3.8 billion years ago and that the chemical record of that time exists deep in the rocks.

Saturn's moon Titan has a thick N_2 atmosphere with some proportions of CH_4, a reducing atmosphere as postulated by the "primitive soup" theory. There is evidence for continents covered with frozen water that are surrounded by oceans of liquid hydrocarbons. The visit of the Huygens probe on Titan indicated the occurrence of complex chemical processes at the surface as well as in the atmosphere. However, at temperatures of about −180°C organic reactions will proceed at a very slow rate. Because H_2O is solid, only a completely different pathway of chemical evolution using hydrocarbons, such as methane as solvent, could lead to some sort of biochemistry.

Verification Problems of Theories on Chemical Evolution

Any theory that proposes an explanation for chemical evolutionary processes is confined to an incomplete description. This is due, among other reasons, to our fragmentary knowledge of the primitive Earth, its atmosphere, and its detailed geological features, as almost no geological record from that time is conserved. Hence, it is impossible to imagine all possible sites where relevant chemical processes could proceed. Therefore, some local particularities that might have been decisive cannot be taken into consideration.

Nevertheless, this is not absolutely necessary as scientists are searching for plausible environments of chemical evolution. The exact place and the order of the pivotal processes of chemical evolution are and always will be out of the reach of scientific knowledge. Plausible environments are characterized by several features, such as availability of energy, input of molecular building blocks, and possible sites for accumulation and further modification of the generated molecules. Besides, every theory has to focus on a few central aspects of chemical interaction, simplifying other features of the environment, because it is not possible to include all potentially important characteristics within one theory. Thus, every theory may include some crucial features of the then-process.

One basic objection to any hypothesis is that it is not known how first life developed and how it was constituted. Most hypotheses assume a similar but much simpler constitution than extant life, and there are only a few hypotheses that propose first living systems on a completely different basis.

Limitations of Simulated Chemical Evolution

An experiment can only be as good as the hypothesis on which it is based. Experiments cannot take all environmental features into consideration, but some environmental conditions, over a certain period of time, might facilitate a complex process like chemical evolution. A high complexity in the interplay of the contributing factors to chemical evolution would hint at a singular process. If that process was singular, however, then a theoretical interpretation and an experimental repetition would be almost impossible.

Other challenges of experimental simulations are time and the rate of investigated reactions determined by kinetics. Chemical evolution might have required a time span of some 10 million years; thus, slow reactions also could have influenced the process. Such slow reactions proceeding over a period of, for example, 1,000 years may lead to a slow accumulation of certain reaction products that were important for chemical evolution. In the laboratory, such reactions have to be sped up by changing the reaction conditions to be able to detect some products at all. Different or more drastic reaction conditions may generate secondary reactions that change the primary result. Therefore, the outcome of simulation experiments has to be interpreted carefully.

Furthermore, experimenters may encounter other time problems when investigating buildup processes of various monomers, for example, amino acids to peptides. Statistics show that a huge number of possible sequences in a peptide results from the combination of few different amino acids. Hence, it will take many runs to find a desired peptide with a certain sequence.

Finally, it will be always uncertain whether experimental results show one feasible pathway of chemical evolution or the actual process of chemical evolution having proceeded on Earth.

Recent Chemical Evolution on Earth

Hypotheses about recent biogenesis existed until the mid-19th century. Then, Louis Pasteur showed that life is not spontaneously generated in rotten organic material, concluding that all life is generated from other life.

All living species known on Earth are based on the same basic principles. Thus, if there are still places where chemical evolution evolves into living systems, they will be somehow remote. Otherwise they would have already been detected. Because bacteria have been discovered in secluded areas as deep as several kilometers in the rock, such places or recesses at the bottom of the sea may be promising candidates. Energy could be provided by radioactivity or geochemical reactions there. However, it remains uncertain how such processes can be identified, considering that organic material is permanently produced and altered by natural processes and living species.

In general it is unlikely that processes similar to those that led to first life on Earth still occur, because the environmental conditions (e.g., the composition of the atmosphere) have changed much since then. This is due to chemical evolutionary processes that continually change the environment. Besides, there always will be interaction between living species as competitors for energy and nutrients.

Can Simulated Chemical Evolution Create Life?

Laboratory experiments can generate the basic constituents of modern life in chemical evolution simulations. Furthermore, the simulation of basic processes in living systems like replication, in the case of separate ribonucleic acid (RNA) strands and their replication enzyme, and metabolic reactions can be performed in the laboratory.

Nevertheless, these experiments are still remote from the creation of an interaction of the separate and complex replicable and metabolic machinery. These two running systems show a complex interplay so that the mixing of all necessary proteins and the genetic apparatus from dead bacteria in a nutrient-rich environment would probably not start new life easily. It is not sufficient to put all relevant molecules together to start life, as illustrated by the analogy that a heap of bricks is still far away from being a house. At present, the only possibility of simulating life-like systems is by computer modeling.

One can still imagine that simple living systems may arise unexpectedly and with uncommon characteristics in laboratory experiments. Such systems are difficult to predict because they may differ remarkably from known systems. It is uncertain whether such emerging living systems would form at all and whether they would be recognized as life.

Could Chemical Evolution Occur Again on Earth?

Because there is still disagreement about how chemical evolution, leading to life, once proceeded and how unlikely this process is, it is rather difficult to predict the future. Starting from restrictions on possible present chemical evolution, future processes also will be limited to niches in remote areas. These restrictions seem even more plausible as an extinction of life may be caused or accompanied by some sort of environmental catastrophe that deteriorates the atmospheric situation. Future chemical evolution, if possible, would probably have to choose different pathways due to other environmental conditions.

Evolution, Cosmic

Cosmic evolution can be defined, in the simplest terms, as the scientific study of change as it has occurred since the beginning of this universe. The age of the universe is now estimated to be approximately 14 billion years. The concept of the arrow of time has been employed to record the major changes that have resulted in the universe's increasing complexity. Cosmic evolution focuses on the interconnectedness of all parts of the universe. This orientation can be noted at least as early as the 16th century in the writings of Nicolaus Copernicus and Galileo Galilei. The idea of the centrality of planet Earth was abandoned only in the past several hundred years. The movement toward more critical thinking about humans and the universe was a prominent element of the Renaissance.

Julian Huxley, a 20th-century British biologist, is associated with a scientific approach to the study of cosmic evolution. Pierre Teilhard de Chardin, a 20th-century French geopaleontologist and Jesuit priest, emphasized the religious aspects of cosmic evolution. Mainstream scientists have generally taken an objective orientation, claiming that it is crucial to continually gather and test data to further our general understanding of the order and nature of this universe. Implicit in these attempts is an implication that humans, however important and advanced at present, should not be considered as unique or as the center of the universe. The study of cosmic evolution is becoming increasingly interdisciplinary in that it includes scholars in astronomy, physics, chemistry, geology, biology, and anthropology. Recently, physicist Eric Chaisson has written extensively on the seven major stages of cosmic evolution: particulate, galactic, stellar, planetary, chemical, biological, and cultural.

The *particle epoch* refers to the first few minutes after the big bang that scientists generally agree created our universe. The big bang itself probably took only a few seconds and could be described as the beginning of the arrow of time, or of time itself. At that point, the intense energy kept matter from forming even elementary particles. The weakening and cooling of energy initially resulted in the production of hydrogen, the lightest and most common element in our universe. Research on the *galactic epoch* represents special challenges to scientists. Though galaxies have been observed throughout the universe, there are still questions about exactly how they were formed. It is generally concluded that most were formed during the universe's first billion years, and that conditions conducive to their formation are no longer present. The conditions that first produced stars during the *stellar epoch* still exist at the present time. Astronomers have observed new stars being formed in the Milky Way. For stars to form, stellar gas must combine with large amounts of matter. The sun is an example of a star with medium mass that has lasted around 5 billion years and is expected to last at least that long into the future.

The *planetary epoch* is generally assumed to have developed as the result of the stellar epoch, since planets appear to form as the result of the explosion of stars with a large mass. At the time that the sun was forming, around 5 billion years ago, other planets appear to have been formed by the fragmentation of a large ball of gas and dust. Earth is an example of a planet closer to the sun, which accounts for its smaller size and rocky surface. Under the original harsh conditions, it seems likely that life did not yet exist. Earth is also held to be approximately 4.6 billion years old. During the *chemical epoch* the available energy resulted in the growing complexity of simple chemicals that would eventually make life itself possible. Perhaps 4 billion years ago, the *biological epoch* began with the formation of the earliest and simplest forms of life. Fossil records have indicated that a particularly diverse set of new life forms appeared during the Cambrian period, about 550 million years ago. Compared to other forms of life and complex organisms, humans have existed for only a few million years, with more advanced humans appearing only about 150,000 years ago.

The *cultural epoch,* the seventh and final stage, includes the present day. The most rapid period of advancement of civilization took place within the last 10,000 years, including the rise of technology, the development of symbolic language as articulate speech, and even the desire and ability to measure time itself more accurately. This fertile period represents just 1% of human history. As humans evolved, an actual increase in brain size occurred. Those changes increased their capacity to acquire and store information and to pass it on to others, as well as to have the curiosity and ability to tackle a topic as complex as cosmic evolution.

Chaisson emphasizes the importance of energy in the evolutionary process. Though the amount of energy in the universe is fixed according to the conservation principle, cosmic expansion has resulted in an ever-increasing energy flow per mass over the past 10 billion years. Galaxies, stars, planets, and various life forms can be described as open systems. They are able to exchange energy and matter with their surroundings. The increased energy that results may explain the growing complexity of the universe and the increased order of its various structures. In this sense, a kind of natural selection occurs when a specific system survives because it has been able to process energy at the most efficient level. Chaisson describes the arrow of time as linear and not reversible, with the sequence of the various epochs that occur being more important than identifying how much time actually passed during each epoch. It can be useful to imagine the arrow of time as flexible and able to be modified as scientists gather more data. Fortunately, modern scientists have the advantage of increasingly sophisticated technological resources for finding new data. An important example is the Hubble Space Telescope, a major tool used in the 2007 Cosmic Evolutionary Survey (COSMOS) at the California Institute of Technology. The survey revealed that this universe consists of only 4% ordinary matter. The remainder, not directly observable, consists of 22% dark matter and 74% dark energy.

Cosmic evolution can be described as a historical study as well as a scientific discipline. Scientists strive to avoid being judgmental in their observations, and the interdisciplinary nature of the field can only increase the scope of what scientists and other scholars may discover. In addition to satisfying humankind's natural curiosity, the study of cosmic evolution is an important way of linking the past with the present and speculating on the future. What we learn could also allow us to monitor our impact on evolution in the most constructive way possible.

Evolution, Cultural

The process of cultural evolution is a phenomenon the strict and clear definition of which can hardly be found in contemporary anthropology and philosophy. In most branches of humanitarian knowledge, concepts of cultural and social evolution are viewed within the framework of the entire theory of evolution of human society, which inevitably implies an evolutionary approach to human culture as well. At the same time, the history of cultural evolution conceptualization in anthropological thought proves that the idea of evolving social structures and functions, as well as material culture, throughout a vast period of time has been in this disciple since the middle of the 19th century.

Concepts of Cultural Evolution: The Evolutionist Paradigm

Ideas about the evolution of human culture were formulated for the first time at the end of the 19th century as a logical application of evolutionism to a peculiar branch of cognitive philosophy that was based in turn on an idea of development (mostly progressive in its character) of human beings and human culture over time.

Early ideas about cultural evolution as the essence of human history were expressed by Edward Burnett Tylor in 1865 in his *Researches Into the Early History of Mankind,* in which basic postulates of further understanding of this phenomenon in ethnology, cultural, and social anthropology were expressed. According to Tylor, in all parts of the world, human culture gradually evolves from its savage stage through barbarism toward civilization; cultural differences among different peoples can be explained by the fact that these groups represent different stages of cultural evolution and have no racial or any other implication. Cultural achievements (innovations) could be invented by the cultural group itself or inherited from previous generations; alternatively, they could be also adopted from neighbors.

In a series of subsequent scientific works (*Primitive Culture,* 1871; *Anthropology,* 1881) Tylor improved his understanding of cultural evolution as an immanent process of gradual development that is identical with cultural progress and inevitably means steady perfection of certain cultural phenomena over time. Notwithstanding differences with the so-called degeneration theory of Joseph de Maistre, widely popular at that time, Tylor did not totally exclude the possibility of regressive changes in human culture caused by historical and natural catastrophes.

Based on his own original definition of the historical and social essence of culture taken as a general anthropological concept, Tylor provided numerous examples of so-called evolutionary rows, in frames of which particular genres of cultural phenomena and artifacts were arranged in certain sequences, beginning with their simplest form up to contemporary highly developed versions. The "doctrine of survivals," or living cultural fossils (archaic cultural elements preserved from one stage of cultural evolution into the next), was another instrument applied by Tylor to prove that changes of culture through time were progressive and gradual.

An original understanding of cultural evolution as a cyclic process was proposed by another early evolutionist, Adolf Bastian. He interpreted the history of humankind as a continuous round of events that were altered only when new challenges ("irritants") provoked a new turn in the evolutionary process. The more isolated a group is in its life cycle, the more unalterable its culture is, thus providing few chances for evolution. According to Bastian, the deeper the connection certain collectives have with their geographic habitat, the weaker the evolutionary prospects are for their culture.

It should be stressed, nevertheless, that most early evolutionists, such as Lewis Henry Morgan, Herbert Spencer, James G. Frazer, and others, tended to emphasize a stage approach to the interpretation of cultural evolution, stressing universality: Insofar as basic principles of cultural evolution are common for all of humankind, similar stages of cultural evolution yield similar results and outcomes. This thesis was regarded as a substantial background for the creation of global historical periodization of human cultural development and social changes.

Continuity of cultural changes was considered by early evolutionists as one of the basic principles of cultural evolution, and in their understanding these changes were mostly quantitative and did not imply qualitative transformation of the subject under study. Thus, no attempts to explain the history of culture and its components' origin could be traced in the works of these early evolutionists.

Cultural Anthropology Between World Wars I and II

Formation of national schools in ethnography and cultural and social anthropology at the turn of the 20th century brought new insight into the application of cultural evolution in native culture studies and caused broad diversification in the understanding of the essence of cultural changes in time, not limited to evolutionary methodology.

At this time, cultural history occupied the attention of the anthropologist Franz Boas, who effectively dismantled the idea of orthogenic evolution with respect to human society, stressing at the same time that globalization and generalization in terms of cultural essences carries the risk of veiling the real cultural diversity of the world. He believed that every culture has its own history that is unique and precious. Thus, the development of culture should not be labeled as progressive, cyclic, or regressive as was done by early evolutionists. According to Boas, cultural changes reflect the peculiarities of the inner social development of a group as well as external social and environmental impacts, which cause an elaboration of peculiar modes of life or human behavior.

His followers, representatives of the historical school of cultural anthropology, were far from understanding the history of a culture as an evolutionary process progressive in its inner essence. They tended to explain the dynamics of culture in time mostly by processes of cultural diffusion, which imply broad intercultural interaction. Similar cultural phenomena could be caused by principally different challenges and have different origins.

Further studies in the field of cultural changes in time are connected with the name of Melville Herskovits, who argued that morphological differences between humans, geographic position of a group, and mode of production could not be regarded as the basic determinants of certain cultural origins and changes over time. According to his views, which became the theoretical background of cultural relativism, every culture is equally valuable and important, representing a unique cultural focus that is highly distinctive and often cannot be compared with cultural focuses of other cultures. Denying ethnocentricity in any form, cultural relativists regard the history of humankind as a set of independently developing cultures, each of which is at the same time stable and variable; this cultural variability is the basic source of global culture dynamics in time.

Neoevolutionary Interpretation

The constructive critique of early evolutionists' linear understanding of cultural evolution by most ethnological and anthropological schools of the first half of the 20th century provoked a fundamental revision of the theoretical background of evolutionists' theory of cultural dynamics and gave rise to the peculiar ideology known as neoevolutionism.

Within this framework, evolution is viewed as forward movement stimulated by an indefinite set of reasons, motives, and challenges. Their detection is the focus of most of representatives of this theoretic branch of cultural anthropology. Diversity in understanding of the cultural essence of evolution and the peculiarities of its realization within certain human groups is perhaps the most striking feature of the neoevolutionist understanding of cultural evolution. Interpreting culture as a set of interdependently and pluralistically evolving systems is typical of neoevolutionists. The question of the universality of stages in the historical evolution of culture is another subject of sharp theoretic discussion among neoevolutionists, along with the idea of multilinear forms of cultural evolution.

One of the most widely known versions of neoevolutionistic interpretation of cultural changes through time is represented in series of monographs by Leslie A. White (*Science of Culture,* 1949; *Evolution of Culture,* 1959). According to White, cultural evolution is a unified process of development in which one form is growing through another in chronological consequence; every form of culture in this context is shaped by a combination of different elements of culture. He believed the basic reason for cultural evolution was the improvement of human adaptation to the world, and he suggested that the degree of success of this adaptation could be measured rather precisely.

White believed that energy is the basic source and driving force of any process, cultural evolution included. Energetic richness of a culture is the main criterion of its maturity, and cultural progress could be measured by quantity of energy per capita used annually by its transmitters. In this way, progressive forms of cultural evolution implying improvement of human adaptation were associated with a growth in power consumption.

Julian Steward, another famous representative of neoevolutionism, also tended to link cultural evolution with human adaptation. In his *Theory of Culture Change: The Methodology of Multilinear Evolution* (1955), Steward proposed an original interpretation of culture as a peculiar system of evolution determined by the necessity to adapt to particular geographic environments. Taking into account the variability of geographic situations and the plurality of its changes through time, cultural evolution inevitably displays itself as a multicircuit process resulting in a plurality of cultural phenomena and forms. The origin of the latter he proposed to explain by correlation among peculiarities of natural environment, technological parameters of certain societies, and specific features of its activity (functioning).

Adhering to a pluralistic version of cultural evolution, Steward believed that different cultures could develop in fundamentally different ways, and this difference depends on the plurality of their adaptation to natural environment: Peculiar landscapes elicit an elaboration of peculiar adaptive forms and elements of culture. He put into scientific circulation the notion of "cultural ecology," which describes the process of human cultural adaptation and the interaction between culture and the natural environment. Cultural adaptation was understood by him as a permanent and perpetual process, inasmuch as no known cultures have failed to adapt perfectly to their niche.

On the basis of his original understanding of the role of natural environment in cultural evolution, Steward detected the phenomenon of "parallel evolution," which implied that cultures of human collectives living in similar geographic situations and characterized by similar technology evolve similarly, even if they are located far from each other and have no direct or mediated contact.

It is worth mentioning, nevertheless, that Steward was rather far from simplistic explanations of all elements of culture and their changes through time by ecological adaptation. In his works environmental impact on cultural evolution is viewed dualistically: The geographic situation stimulates the elaboration of certain forms of culture and, at the same time, restricts realization of some innovations. He was a proponent of the pluralistic approach to the conceptualization of the role of environment in cultural evolution, suggesting that at the early stages of cultural evolution, human culture mostly was prone to environmental impact, while the cultural compass of societies with highly developed technology is considerably wider.

In contemporary cultural anthropology, neoevolutionistic ideas concerning plurality and multicircuitry of cultural evolution have been developed by Marvin Harris. In his *Cultural Materialism* (1980), he argues that cultural evolution results from, and is stimulated by, satisfaction of human needs with the help of technologies that show strict correlation with peculiarities of environment at certain periods of time and imply optimal forms of exploitation of available resources using minimal expenditures of labor and energy.

Recent tendencies in the study of cultural evolution are connected with a symbolist approach to culture as a global phenomenon. One such version is represented by Charles Lumsden and Edward Wilson, who identified the central importance in cultural evolution of a process they call *reification,* for which the enabling device is symbolization. The central place in this process is occupied by language as the basic means of symbolization, whose origin and changes over time are integral parts of the subject field of cultural anthropologists, linguists, historians, as well as geneticists who are studying gene flows and reconstructing, on this basis, cultural contacts and further cultural changes. Recently, Richard Dawkins introduced the notion of a *meme*—a replicator of cultural information analogous to the gene. On this basis a wide variety of computational approaches to cultural evolution have been elaborated, most popular among which are Liane Gabora's MAV (meme and variations) model, David Ackley's concept of distributed Lamarckian evolution, Lee Spector and Sean Luke's idea of cognition evolvability, and others.

Evolution, Issues in

There is no shortage of issues in evolution. Some are highly contentious, others are benign. Evolution, by its very nature, is prone to controversy because it is largely a science of inference about a historical process, a process that takes place over time and space. Evolution involves unique events that can never be revisited in their entirety and can only be reconstructed through evidence associated with those events. In this way, reconstructing evolution is methodologically no different from a process of detective work that attempts to reconstruct a crime scene or any other event that has occurred only once. Because evolution is a historical process, its expression over time provides the focus for many of the uncertainties and questions in the science of evolution. These challenges may be relatively ephemeral as they are recognized and solved, or they may persist over longer periods before being solved or reformulated, or they may even emerge again under new scrutiny or with the discovery of new evidence. In evolutionary research, time is of the essence; it must always be addressed. This entry illustrates some of the issues in evolution that focus on, or are derivative of, evolution in time.

RNA or DNA?

A central dilemma for understanding the genetic origin of life is the identification of a stable, self-replicating genetic molecule that simultaneously carries the information necessary for copying itself and for catalyzing that replication process. Modern life relies on two complexly interrelated molecules for this process: DNA (deoxyribonucleic acid), as a carrier of information, and proteins, which perform chemical reactions. Proteins are involved in the formation and maintenance of DNA, and yet DNA is required for the protein formation instructions. This dual function raises the question of which process came first. One possibility is that a self-replicating peptide or other protein molecule evolved first, and DNA became possible as a result. The problem with this model is that it requires a random assembly of amino acids to form chainlike polymers rather than irregular clusters. A simultaneous evolution of proteins and DNA would require two improbable events. The evolution of a sequence of elements that replicates and also provides the template of replication represents another possibility, suggested by the role of RNA (ribonucleic acid) in living organisms.

The single-stranded nucleic acid molecule known as RNA can function both as a carrier of information and as a catalyst promoting the self-replication. RNA also includes genes that accelerate biochemical reactions. RNA has the potential to make and maintain DNA as well as proteins. This RNA theory suggests that life may have first begun as an "RNA world" of organisms that preceded the evolution of DNA life. The RNA world theory suggests there was a time when RNA rather than DNA was the primary mechanism of storing genetic information, but when replication of genetic material already followed the same rules as modern DNA by matching the amino acid adenine with uracil (equivalent of the DNA thymine) and cytosine with guanine. This ancient, ancestral RNA is theorized to have played the same catalytic roles as modern protein enzymes where the first genetic life-form was simply a self-replicating strand of RNA that may have been enclosed within a protective lipid membrane while modern metabolic processes, with an efficient replication process, emerged later.

If life and genetics are synonymous, the evolution of life through an RNA world may represent the beginnings of modern life. The possible antiquity of RNA implied by the RNA world model is emphasized in biochemical studies showing that RNA molecules play key structural roles in the formation of a variety of essential coenzymes that mediate manufacture of lipids and other biological molecules. RNA also includes genes that change shape when binding to specific cell molecules and regulates cell chemistry by turning genes on and off. There is widespread agreement that RNA represents a critical step in the origin of life, but after decades of chemical experiments, the emergence of a fully functional RNA world from earlier prebiotic chemical solution remains problematic.

The RNA theory provides no insight as to how life first made the transition from a prebiotic solution of biological molecules to those of DNA and cellular life. There may have been a critical transition stage, such as a metabolic system, that was followed by a genetic molecule that was structurally simpler and chemically more stable than RNA. Metabolism initially uses relatively simple molecules (carbon-oxygen-hydrogen and possibly sulfur), whereas RNA function relies on exact sequences of chemically complex nucleotides involving a carbon-oxygen-hydrogen-nitrogen-phosphorus system. Biologists are generally confident that there was a transition from an RNA world to the current DNA-protein genetic system, but how the prebiotic molecular world evolved the linkage between individual nucleotides comprising an RNA strand remains unsolved.

Viruses as Life

Viruses cross the boundaries that are used to define the concept of life. In general, evolutionary biologists may not give due consideration to the role and contribution that viruses have made to the origin and evolution of life. This oversight may be due, in great part, to a widely held view that viruses do not represent living entities and do not, therefore, represent significant elements or contributors to the tree of life. But viruses can be killed, can become extinct, and adhere to general rules of evolutionary biology, including the process of natural selection. And they do have a large impact on the survival and evolution of their hosts.

The determination of viruses as living or nonliving entities represents a persistent question since viruses were first identified. As in all other biological systems, viruses store, copy, and express information. In some respects they conform to qualities of organisms that are accepted as having a living state, but in other respects they do not. There is widespread agreement that life is bounded by birth and death for organisms that live with a degree of biochemical autonomy and have the metabolic ability to produce the molecules and energy necessary to maintain life. Viruses, on the other hand, lack biochemical autonomy because they lack the means to produce their own proteins and consequently rely totally on their symbiotic molecular parasitism of other living organisms. Because viruses are parasitic to support essentially all the biomolecular requirements, they may be viewed as nonliving parasites of living metabolic systems. In this context they can be described as metabolically active containers lacking the genetic potential to propagate without "borrowing" life from other living organisms. Viruses may be no more than environmental or chemical toxins that kill off some hosts.

The question of whether viruses are alive may be no more informative than the question of whether a gene or protein is alive. Individual subcellular constituents such as mitochondria, DNA, RNA, genes, enzymes, and cellular membranes all represent levels of chemical complexity equivalent to those of many viruses, and yet they are generally considered not to be living in the same way as cells or organisms are living. Unlike cellular organisms, some viruses can bring themselves back to an active or "living" state and some viruses can replicate in "dead" host cells such as those without nuclei. Where an individual cell is infected by more than one dead virus, the virus can become reactivated when the multiple viral genomes complement the damage and reassemble the "living" virus. This is the only known biological entity to have this capability.

A widely held view on the origin of cellular life is that it first evolved in oceans and that it was preceded by a period of evolution involving precellular, chemical-replicating forms. These chemical entities were able to use themselves as a template for synthesis using existing molecules in the surrounding environment. Given the fact that all cellular life uses nucleic acid molecules as genetic information and relies on protein-based catalysis, the ancestral replicating systems may also be assumed to rely on nucleic acids or related molecules as information storage and biotic synthesis. As the main storage molecule of genetic information in living organisms, DNA is a comparatively chemically inert and stable molecule that cannot perform the catalytic process required for replication. In contrast, RNA is known to function as both genetic storage and as a catalyst of RNA, and autocatalytic RNA may have been the principal molecule used as both information storage and catalysis in the prebiotic world. RNA can break the molecular bonds of RNA, although it is comparatively inefficient in constructing new RNA molecules. If more efficient replicating systems did not exist in the prebiotic world, then this inefficient RNA-based process may have represented a viable system of replication. With the subsequent emergence of protein catalysis and faster replication processes, the prebiotic RNA replicators would have became extinct, with the possible exception of RNA viruses as the sole living descendents of the prebiotic world.

Viruses are obligate intracellular parasites. They cannot replicate outside cellular environments. This current condition may be seen to preclude the existence of viruses before the evolution of cellular life. If, however, viruses are recognized as molecular genetic parasites, they may be capable of parasitizing any replicating systems, including other viruses, and any prebiotic molecular systems. Any genetic replicators, including noncellular prebiotic replicators, would be susceptible to parasitic replicators or viruses, as are viruses parasitized by other viruses. These parasites of parasites could be anticipated to have also existed in the prebiotic world.

No fossil record of viruses has been discovered, so there is no external reference to calibrate the origin of various virus lineages. As prebiotic life forms, viruses would have to precede the first record of prokaryote cellular life (bacteria), about 4 billion years ago, and the cyanobacteria (blue-green algae), about 2.6 billion years ago. Each of these groups has distinct and characteristic viruses, but they also share the presence of tailed viruses and this may be the result of this group of viruses evolving prior to their divergence. The earliest eukaryotes (unicellular algae) appear in the fossil record between 2.2 and 1.8 billion years ago, followed by relative evolutionary stasis until the Cambrian explosion with the appearance of numerous skeletal organisms. The evolution of these forms also is likely correlated with the emergence of many types of viruses.

Viruses appear to have numerous evolutionary origins as indicated by the different specific genome replication processes of individual virus families, suggesting each virus family derived from a different ancestor. Other viral groups are so large and diverse that available sequence data currently do not support the view that even they evolved from a single common ancestor.

It is now widely thought that viral lineages are old, and they originated independently of the replication system in their hosts, and there are several independent origins for viruses.

Origin of Complex Life

There is no objective demarcation between "complex" and "simple" life, but a major organizational difference separates unicellular and noncellular organisms from multicellular organisms (Metazoa) where specialized cell functions are present. Metazoan cells are interpreted as descendants of unicellular organisms that may also have a composite origin involving the combination of noncellular organisms resulting in the metazoan cell with a central membrane-bounded nucleus surrounded by cytoplasm with specialized organelles. The combination or incorporation of precellular organisms would explain the occurrence of nonnucleic DNA in organelles such as mitochondria and chloroplasts.

In the context of relative complexity, the combination of cells results in new features not present in unicellular organisms, such as extracellular matrix providing support for the cells and including gelatinous matrices infused with fibers such as collagen and other macromolecules. Metazoan cells comprising tissues are also connected to each other by molecules that form attachments and also permit intercellular communication. Most tissues comprise sheets of cells that are usually interconnected and have apical and basal regions and are usually attached to a basal layer of extracellular matrix. Connective tissues are also embedded in extracellular matrix, but they are not as closely associated. Another major tissue category is nervous tissue, which forms the main integrating and coordinating system of the body and is present in almost all free living metazoans.

The Metazoa comprise a range of contrasting body structures that appear abruptly in the fossil record and lack intermediates. The Metazoa appear to be monophyletic (share a most recent common ancestor not shared by nonmetazoan life), but the arrangement of major lineages (phyla) is variable even though many researchers use the same information. In morphological studies, the Cnidaria (jellyfish and their relatives) are often represented as one of the earliest of living metazoan phyla. Even the Chordata, which mostly comprise the vertebrate groups (fish, amphibians, reptiles, birds, and mammals), are often treated as having originated near the beginning of metazoan life and are often linked with the invertebrate Echinodermata (starfishes). Molecular phylogenies have yielded some different results, some suggesting that cnidarians evolved independently of the remaining bilaterally organized metazoans.

Two main evolutionary issues concern when metazoan life evolved and in what sequence. The branching order of lineages may be theorized through phylogenetic analysis that predicts their evolutionary relationships. This order may be compared with their order of appearance in the fossil record, and where the two sources of evidence coincide, the sequence may be viewed as an accurate representation of metazoan evolutionary history. This approach is challenged by the uncertainties of fossilization, and soft-bodied organisms, particularly those that are unicellular, are rarely preserved as fossils. The definition and dating of the earliest geological formations in relation to the fossil record may also be problematic. The earliest rocks dating from about 600 million years ago (mya) comprise the Neoproterozoic era until the beginning of the Cambrian period about 543 mya. Metazoan fossils earlier than about 565 mya are limited to embryos, body fossils, and traces of metazoan activity and include the sponges as the only living metazoan phyla represented, although Cnidaria (jellyfish) are thought likely present because they represent a basal or primitive lineage. Later Neoproterozoic fossils include small, shelled fossils. The first appearance of recognizable trace fossils (formed by disturbance of sediments by the activities of an organism) formed by a series of straight to curving segments mark the beginning of the Cambrian about 530 mya. The Cambrian fossil record includes the first appearance of 11 of the modern phyla, including mollusks, arthropods, starfish, and chordates. From the end of the Cambrian (490 mya) to the beginning of the Mesozoic (248 mya) only four additional metazoan phyla first appear, whereas most of the remaining phyla either have a post-Mesozoic (65 mya) fossil record or lack a fossil record altogether (14 soft-bodied phyla).

Cambrian Explosion of Life

Fossils may raise as many problems as solutions for scientists who track the temporal origin and sequence of life in the fossil record. Fossils are informative in the sense that they provide empirical evidence for the existence of an organism at a particular place and time. But they are less informative about the evolutionary identity and the relationship of that past organism to modern life. This problem occurs at all levels, from identifying a species relationship for recent fossils (e.g., whether Neanderthals are a separate species or a variation within modern humans), to their placement at a higher taxonomic level such as a genus, family, order, class, or phylum. These problems may be compounded by the lack of preservation in fossils, particularly the general absence of information on soft-tissue organization. Even features that do fossilize may be only partially preserved.

Fossils also yield ambiguous information about the timing of evolutionary events. The oldest fossils represent forms that can be identified only at a high level of classification, that they represent, for example, a bacterium, a single-celled organism, an animal, or a plant (and even then, the identification may be uncertain). The oldest recognizable fossil for any particular group of organisms also cannot provide any temporal information other than the minimal age of fossilization of that group.

How much the origin of a group may precede the fossil record cannot be directly gleaned from the fossil itself. Given this limitation, the fossil record is presumed to give a reasonable indication of historical sequence as more derived groups (e.g., mammals) appear in the fossil record later than those that are more generalized (e.g., fish or invertebrates). When larger groups representing many species are absent from the fossil record, there may be greater confidence that they are either rare at that time or had not yet evolved. There may be a relatively high level of confidence in correlating fossil appearance with the timing of evolutionary origin when skeletonized organisms are involved, but in the absence of skeletons the lack of fossilization may represent the relative rarity of conditions for fossilization of soft tissues rather than an actual absence. In dealing with the origin and first appearance of skeletal life, this is a major constraint on scientists' efforts to identify the temporal origin of skeletonized organisms.

The problem of correlating the first fossil appearance with evolutionary origin is exemplified by the various multicellular phyla that first make their appearance in the fossil record during the Cambrian period that began about 543 mya and lasted until 490 mya. The earliest Cambrian fossils indicate an increase in biological diversification and body size compared with Precambrian organisms. The earliest fossils are traces of movement or occupation of sediments by organisms and mineralized skeletons that increase in diversity during the first 15 million years of the early Cambrian. The traces are also larger and more diverse than Precambrian traces and include branching burrows and larger vertical burrows. Major locations recording diversification of Cambrian life include the Chengjiang fauna from Yunnan, China (Middle Cambrian), and the Burgess Shale formation, British Colombia, Canada (Middle Cambrian).

Precambrian fossils that may be recognized as members of living metazoan phyla are limited to sponges, although the soft-bodied Cnidaria (jellyfish) are presumed to be present. In the Early Cambrian, about 530 mya, fossil members of modern phyla that first appear include single- and double-shelled mollusks (snails and shellfish), echinoderms (starfish), annelids (worms), Cnidaria (jellyfish), chordates (precursor to vertebrates), a diverse array of arthropods (bodies with external, jointed skeletons), many of which cannot be assigned to living arthropod classes, and forms that may represent primitive fish. It is the arthropod groups that show the most striking diversification of body structures, including many that are distinct from later arthropod groups, and others that look like members of the phylum Onychophora, a living group that may represent a transitional stage between soft-bodied annelids and the externally skeletonized arthropods.

Because these fossils appear over a geologically short period of time, their pattern of fossilization is characterized as the "Cambrian explosion." The appearance of these fossils would represent a comparatively rapid explosion of evolutionary diversification if the fossil record accurately represents their evolutionary origin. Because most of the diversity corresponds to organisms that have evolved durable, mineralized skeletons, their fossil appearance may be an artifact of fossil perseveration, representing an increase in the durability of skeletal structures rather than their first appearance. Evidence that may suggest the fossil record corresponds to a rapid diversification during the Early and Middle Cambrian is found in groups that appear to have required durable skeletons to function so their evolutionary origins may be no earlier than the origin of their durable skeletons. The large increase in trace fossil abundance and variety also began only shortly before the fossil explosion and may suggest that many of these groups may have first evolved around the time of their fossil appearance. There is also the possibility that the ancestral forms of the Cambrian phyla were present in the Precambrian, but rarely preserved, if at all. As with any fossil record, the absence of earlier fossils does not preclude an earlier origin, which may be corroborated only through later fossil discoveries.

Origin of Sex

Sex involves the coming together of complementary cells, where the biological attraction is strong enough to recombine genes, with the result that the new organisms are genetically different from their parent cells. Understanding the evolutionary and temporal origins of sexual reproduction is linked to understanding the origin and evolutionary relationships of organisms that may be classified into five main reproductive groups. Two groups are entirely or principally unicellular. The bacteria are single-celled organisms that lack nuclei. These organisms reproduce through binary fission, although bacteria may also incorporate genes from other bacteria or absorb genes that have been released into the surrounding water from dead bacteria. The protocists comprise cells with a nucleus (including algae, slime molds, and ciliates) that also often reproduce through binary fission, but also sometimes exhibit cellular fusion. Most protocists are single celled, but some form colonies of cells that adhere together.

The multicellular groups comprise the fungi, which reproduce through the production of spores, the plants that reproduce from both spores and the cellular unions that produce embryos, and the animals that develop from the union of egg and sperm. It is in plants and animals where sexual reproduction requires cellular fusion followed by the division of a fertilized egg that forms the embryo. This process requires an alternating halving and doubling of DNA in each generation and a correlated parental mortality.

The origin of multicellular organisms from unicellular ancestors appears to involve not only the adherence and intercommunication of individual cells but also novel combinations of unicellular organisms. Both animals and plants include organelles that have their own DNA (mitochondria in animals, chloroplasts in plants). Some comparative studies have resulted in the proposition that protocists first evolved through the integration of bacteria, and this process of symbiosis may also have significant implications for the origins of metazoan sex. Each generation of animals reverts to what is effectively a single-celled protocist-like stage, and the mammalian fertilized egg may resemble the ancestral protocists that evolved the first doubled chromosome complement. But instead of remaining a single-celled organism, the cells of this ancestor stayed together and formed an embryo with differentiated tissues and organs.

The origin of sex in plants and animals would appear to be contemporaneous with the evolution of multicellular organisms that develop from an embryo. The reproductive links may be indicated in some protocists where asexual and sexual reproduction is present along with multicellular organization. Seaweeds comprise single algal cells that remain together, but they are not plants in the sense that they do not develop from an embryo. In some algal colonies any one cell may break away and start another colony, whereas others (e.g., *Volvox*) form small colonies within themselves that are later released when the gelatin holding the parent colony together dissolves. Some *Volvox* colonies will produce cells that function as ova and others that function as sperm that swim to and fertilize the ova. The fertilized ova forms a zygote within which meiosis will take place, and each resulting cell will begin a new colony.

The presence of sex within protocists suggests that sex may be as old as the protocists in general. There is no direct way of dating this origin. The earliest metazoans may extend back as far as 600 mya whereas the first protocist evolution may have taken place at any time earlier when life was first possible on the planet, perhaps 3.8 billion years ago. Even with such uncertainties, sex would seem to have a history as old as that of cellular life, and sexual reproduction through the formation of embryos may even have preceded the evolution of the multicellular organisms that comprise the plants and animals that dominate life's diversity in the present.

Punctuated Equilibrium?

A long-standing question is whether the rate of evolution is constant over time or whether it is variable with periods of rapid evolution and other periods when little or no evolution takes place (stasis). The concept of punctuated equilibrium represents a proposal in favor of evolution alternating between sometimes long periods of stasis punctuated by periods of rapid evolution during speciation. Punctuated equilibrium was popularized in the English-speaking world by Niles Eldredge of the American Museum of Natural History and Stephen Jay Gould of Harvard University. They introduced the concept of punctuated equilibrium in response to an incongruity between the fossil record and the popular version of evolution as a gradual process of evolutionary change over time.

Eldredge and Gould observed that Charles Darwin emphasized a process of gradual evolution, but this theory was incongruent with the expectation that this gradual evolution would be observable by the prevalence of transitional forms between very similar stages in the fossil record. In reality, although a series of transitions in succeeding geological layers over time could sometimes be observed, in most cases there were gaps between the older and younger fossils. The lack of transitional forms was attributed by Darwin to the incomplete nature of the fossil record; transitional forms were missing because they were often not preserved. In this way, the fossil record was misleading about the process of evolution over time by giving the impression that evolution was a continually interrupted or punctuated process.

Not all evolutionists supported the theory of gradual evolution, and some proposed major evolutionary changes whereby new species or forms appeared without any identifiable intermediate form. These "saltationists" included Richard Goldschmidt, who proposed that species could give birth to entirely different forms that were anatomically different from their parents. As this process was not observed in the laboratory, it raised many questions about how such a novel form could survive and reproduce, and Goldschmidt's theory did not gain wide popularity among evolutionists.

Some fossil gaps may be apparent rather than real, where speciation occurred through dispersal to another locality where a new species evolved, and this did not overlap the related species until a later date when it would also fossilize in the same location and give the appearance of a gap. But that theoretical possibility notwithstanding, Eldredge and Gould argued that between the gaps in the fossil record were relatively long periods where a species persisted and that the problem with the fossil record was less that there were gaps than that there were these periods of stasis suggesting that evolution was not a gradual process.

As well as a description of the fossil record, punctuated equilibrium was also proposed as an evolutionary mechanism, based on conventional speciation theory and the notion of adaptive change through natural selection, which explained the origin of reproductively isolated communities over time. They argued that most anatomical change, whether or not it was adaptive, does not occur throughout the bulk of a species' history but during rare events when reproductively isolated species bud off from parental species. Most species do not have a continuous distribution but comprise geographically isolated populations, and given physical isolation of relatively small populations on the edge of a species range, it was possible to get adaptive divergence taking place. This divergence was rapid over geological time although it was not ecologically instantaneous and may involve tens of thousands of years and may mostly involve small evolutionary changes.

As a pattern, punctuated equilibrium described the apparent stasis of species evolution interrupted by speciation taking place over relatively short time intervals. As a mechanism, punctuated equilibrium represents a theorized mechanism based on natural selection of isolated populations affected by changes in the environment. This mechanism may be problematic for many situations where related species are vicariant (replace each other in geographic space) and each occupies a relatively broad geographic distribution, which may suggest speciation involves multiple populations. New developments in developmental and molecular biology also suggest the possibility that the "sudden origin" of new species or morphological structure may take place without necessarily requiring natural selection as the driving force. This is particularly significant for the origin of species over broad geographic areas that span many different local environments and populations that may be broader than the effect of natural selection at the local level.

Continuum

Evolution, by its very nature, is a theory about continuity. But in the present, life is full of discontinuities between those individual organisms that are involved in a close biological (usually reproductive) relationship and those that are not. The sense of discontinuity is also seen in the fossil record, where distinct species or other groups appear or disappear without apparent intermediate forms. The appearance of discontinuity is often seen as more of a problem for evolution than that of continuity and results in various theoretical solutions, ranging from that of punctuated equilibrium to proposed molecular and developmental transitions of entire organ or tissue systems rather than always through incremental and gradual evolution by many small steps.

Biological continuity may be seen in those individuals grouped into units called species. Most species are sufficiently distinct as to be almost self-evident, but limited cases involving various levels of hybridization and different modes of reproduction have led evolutionists to propose universal criteria for recognizing and distinguishing species. In most cases these attempts have focused on the creation of definitions that are true regardless of time and space. These definitions act as essential qualities or essences by which a species may be recognized and often center on reproductive relationships involving criteria such as a reproductive isolation (and its converse, mate recognition) with many, many scientific arguments about whether a species is a "true" species or not. All criteria of this kind are independent of a particular place and time and measure the status of a species solely on whether or not it conforms to the definition. In this approach, species are being defined according to an essential attribute (such as reproductive isolation) or essence.

The problem with essence as the attribute of a species is that essences do not evolve over time or space, but species do. Ancestral species diverge and become descendant species. For evolution to take place, species cannot exist as the expression of an essence because the essence precludes evolution. Recognition of this problem led to the formulation of species as historical entities or individuals that share a unique common history. At any one time and place, the biological limits of a species may be diagnosed with respect to those features of the organism and environment that are seen to identify the species boundaries. Such species diagnoses are valid in reference only to the specified place and time and do not, therefore, require a species to refer to an inner essence. In practice, species may be characterized by one or more particular features, including morphology or reproductive biology, but there is no absolute demarcation required to recognize these qualities independently of a particular spatial and temporal context.

As historical individuals, species may show evolutionary discontinuities where the biological features are spatially and temporally distinct and continuity where they are not. Evolutionary continuity may be seen over time as descendant species merge at their origin with the ancestor or over space where species may show local continuity in biology or reproduction (e.g., breeding between adjacent populations) or discontinuity where more distant populations are spatially isolated so they never interbreed or are unable to produce viable offspring when brought into contact. Here discontinuity is a function of an overall biological continuity that separates out over time and space. In this context a species, like all other units of biological classification, represents a link in the chain of divergence and differentiation rather than a point of separation and isolation.

Extinctions

The history of evolution is the record of speciation and extinction, from the first appearance of life through to the present. The process of evolution is a complicating factor in understanding extinction. When speciation takes place, there is a transformation of the ancestor into descendants, and this transformation may be regarded as a form of extinction even though the lineage continues to exist. Species may also hybridize, causing the "extinction" of the original forms, at least with respect to their original spatial and temporal characteristics.

Extinction may be fast or slow, and its causes local or regional, and climatic or extraterrestrial in origin. The fact of extinction is not at issue, but the causes and extent of extinction are. Even in the present when the planet is faced with one of the most severe extinction rates over a geologically instantaneous moment of time, there is controversy over what, if anything, can be done about the global destruction of habitat and even climate through human modification and destruction of the environment.

Past extinctions on a similar scale have been referred to as "mass extinctions," when species diversity dropped dramatically and globally. Causes of such extinctions have been attributed to major planetary changes related to the balance of global temperature, the influence of massive regional volcanic eruptions, and climate altered through plate tectonics. Only over the more recent decades has greater attention been given to the extinction role of extraterrestrial objects such as asteroids and comets even though it has long been recognized that the earth has a history of many major meteorite impacts.

Periodic major extinctions became apparent to late–19th-century geologists, who delineated geological layers that could represent particular units of geological time. The sequential arrangement of these layers according to their relative age resulted in the formulation of a geologic timescale. The early geologists relied on fossils to correlate the geographically separate geological layers representing the same temporal units. Through their different fossil compositions, major geological layers could be recognized. The different fossil communities were at first attributed to the separate and sequential creations of life.

Evolutionary paleontologists later came to recognize that the contrasting fossil biotas in the major geological layers resulted from evolution and diversification following major extinctions of previously dominant forms. Several major episodes of global declines in species diversity have been identified over the last 550 million years of the earth's 4.6-billion-year history, beginning with a mass extinction inferred from geological evidence of a catastrophic climatic change to the most recent change characterized by the extinction of dinosaurs as the earth's dominant life form.

Extinction of dinosaurs at the end of the Cretaceous at 65 mya is widely attributed to the impact by a comet that caused a 30-fold increase in iridium deposits at the Cretaceous-Tertiary boundary. A major impact crater that also formed at this time in the Yucatán Peninsula of Mexico is widely believed to be involved with, or solely responsible for, the mass extinction of members of the dinosaur clade except the birds, and perhaps 79% of terrestrial plants and 47% of the marine genera, including most marine reptiles. The extinctions are attributed to the effect of the immediate impact as well as atmospheric dust, acid rain, and the elimination of sunlight sufficient for photosynthesis. The extent and persistence of these effects is, however, uncertain, as some studies suggest the dust may have been rapidly reduced through rainfall, and the correlation of many modern plant and animal distributions with Mesozoic tectonics suggests the widespread survival of many lineages, possibly including some modern bird and mammal groups that then diversified in the Tertiary.

The nature and causes of earlier mass extinctions becomes more difficult to assess. The end of the Triassic at 199 mya is marked by the extinction of 53% of marine genera and 22% of marine families, and 12% of vertebrate families. It is after this extinction that dinosaurs became dominant on the land. The causes of this extinction remain unknown, but possibilities include rapid sea level rise and volcanic eruptions. Only 50 million years earlier was the largest recorded extinction, at the close of the Permian at 250 mya, reducing 57% of all families and perhaps 96% of all species in the sea. On the land there was a 77% reduction of tetrapod families (amphibians and reptiles). Among the marine extinctions, the tropical groups or members of the reef-building community were particularly affected. These relatively large estimates are problematic because there is a lack of complete terrestrial fossil layers from that time and errors in taxonomic classification as well as false extinctions where taxa disappear from the fossil record at the end of the Permian only to turn up again later in the Triassic. The extinctions coincide with the massive Siberian volcanic flood basalts, some degree of low oxygen and other changes in ocean chemistry, and a sudden spike in global temperatures. Explanations encompass a variety of terrestrial factors as well as the possibility of an extraterrestrial source.

In the late Devonian, at 376 mya, 57% of marine genera and 22% of marine families disappeared, including the trilobites. At the end of the Ordovician Period, at 439 mya, the second largest mass extinction induced the disappearance of the trilobite-dominated communities of the Cambrian. There was little life on land at this time, with the earliest fossil evidence of plants in the form of spores from the uppermost Ordovician. The extinction may have occurred through an alternation of cooling and warming over a short period of time, which eliminated 60% of marine genera and 26% of marine families. In the early Cambrian, at 512 mya, the elimination of about 50% of all marine species and geological evidence of sea-level glaciers near the equator at in the Precambrian at 600 to 700 mya have led to the Snowball Earth hypothesis, according to which the entire earth was ice-covered until terminated when carbon dioxide accumulation reversed the cooling. This event is inferred to have resulted in a major extinction of existing organisms, although this impact cannot be measured through the fossil record.

Human Origins

The origin of humans begins at the time when the human lineage separated from the common ancestor shared with the nearest living great ape relative. It is at or after this point of separation that the human lineage (hominids) evolved a new skeletal structure that made bipedalism obligate and freed the forelimbs from necessarily assisting with terrestrial locomotion. In contrast, the nearest great ape relative is descended from a lineage that did not evolve these features even though it too is derived from the same common ancestor as humans.

The hominid fossil record currently extends back about 6 million years with fossils that are mostly assigned to the genus *Homo,* which includes humans (*Homo sapiens*) and the australopiths (*Australopithecus* and *Paranthropus*). There are also four other genera that have been proposed as hominids although the evidence for their being hominids is far more ambiguous as they comprise limited fragments and bipedalism extrapolated from indirect evidence (*Ardipithecus, Sahelanthropus, Kenyanthropus*) or partial direct evidence (*Orrorin*).

The initial separation between humans and the nearest living great ape species was initially thought to have occurred much earlier, as another fossil thought to also be a hominid or close hominid relative dated to about 13 mya. This fossil, known as *Ramapithecus,* was represented by an apelike jaw with humanlike dentition. The fossil was fragmented at the midline of the palate, so the shape of the jaw was not known, but reconstructions suggested it was more like the squat, parabolic shape of humans than the U shape of apes. Paleontologists regarded *Ramapithecus* as a definitive hominid or at the very least a close hominid relative that showed the human lineage first diverged from the common great ape ancestor at least by this time.

An apparently contradictory perspective developed in the 1960s, as biologists started comparing protein molecules, and later, as they focused on DNA molecules. These studies at first pointed to African apes as being most closely related to humans, and subsequently this arrangement was replaced by a closer relationship between humans and chimpanzees because they showed the least amount of molecular differences in their DNA (although the contrast between humans and gorillas and orangutans was also very small). Molecular systematists argued that differences in molecular similarity could also indicate the relative age of divergence between related groups. Where members of a group were equally different from another external group, their divergence was seen to occur at a steady, clock-like rate and this clock-like divergence could be used as a measure of evolutionary time. All that was needed was a calibration point to match divergence with absolute time, so that molecular ages could be given for those species lacking an adequate fossil record. By including species with an accepted fossil record, it was theoretically possible to date the divergence between humans and their nearest living great ape relative.

It is now almost universally accepted as a scientific fact that humans and chimpanzees diverged from a unique common ancestor and that even though chimpanzees are structurally more like gorillas, the latter resemblance is misleading. The oldest fossil members of the human lineage (hominids) date back to about 6 mya, but neither chimpanzees nor gorillas have a recognized fossil history beyond some very recent records. The molecular clock appeared to provide a solution, and calibrated molecular clocks predicted divergence dates of 5 to 8 mya for humans and chimpanzees. This was a much more recent date for hominid origins than suggested by the *Ramapithecus* fossil, but a later discovery of another fossil in the *Sivapithecus* group appeared to provide a solution. *Sivapithecus* was recognized as representing the same group as *Ramapithecus,* and because *Sivapithecus* was the older name, it took priority for naming this combined group that included the former *Ramapithecus.* As more complete fossils of *Sivapithecus* were found, it was apparent that these fossils were distinctly orangutan-like. This similarity was believed to preclude these fossils, including the original *Ramapithecus,* from representing a fossil hominid or even a close hominid relative because orangutans were not believed to be more closely related to humans than were the African apes. The alternative possibility, that orangutans were more closely related to humans than African apes, was not considered. Humans were now promoted as not only having diverged very recently from a common great ape ancestor with chimpanzees, but also having evolved a radically different biology resulting in very little, if anything, that was structurally unique to humans and chimpanzees.

The absence of uniquely shared structures between humans and chimpanzees remained an evolutionary anomaly because the theory of evolutionary classification established over the past several decades is based on the principle that sister groups (those that share a unique common ancestor) also share one or more unique features inherited from that unique common ancestor. In the absence of any other theory of relationship, the lack of unique features shared by humans and chimpanzees could be disregarded, but in the early 1980s evidence for the existence of many features unique to humans and orangutans began to accumulate, and these structural characteristics support a closer relationship between humans and orangutans than humans and chimpanzees. As many as 40 unique features have been identified, and at least 30 are strongly documented comparative studies. If orangutans are more closely related to humans than are African apes, then so too are fossil orangutans relatives such as *Sivapithecus,* which is now dated to about 13 mya. This fossil record may suggest that the divergence of hominids from the nearest living great ape (the orangutan) occurred earlier than the time that the molecular clock theory predicts.

The structural evidence for the orangutan relationship with humans sharply contradicts the widely accepted theory that similarity of DNA molecules necessarily precludes any other pattern of relationship derived from nonmolecular evidence. Unlike the molecular evidence, which does not correspond to any comparable structural similarity between humans and chimpanzees, the orangutan evidence is congruent with the fact that the earliest accepted hominid fossils not only look more like orangutans than African apes, they also include several features that are otherwise unique to orangutans and their close fossil relatives.

The contradiction between the molecular and structural (anatomical, reproductive, physiological, behavioral) evidence for human origins represents one of the most controversial and profound challenges of modern biology. At the very least, the orangutan evidence raises critical questions over the validity of commonly accepted assumptions about molecular similarity and evolutionary relationships, and whether molecular clocks can necessarily identify maximum divergence ages. And yet the orangutan theory of human origin has become one of the least recognized and debated issues in evolutionary biology today. There is an almost total silence on the subject within the scientific community. Such silence fails to apply the scientific method, according to which anomalous results demand further research and investigation. As long as this challenge to mediocrity remains unchallenged, the credibility of evolution as a science suffers. Here time is definitively of the essence.

Teleology

Teleology is a temporal concept of causality by which a current structure or process originates in order to serve a future purpose or goal. In this concept it is the future that determines the past and the present. Teleology was the predominant mode of reasoning to explain the natural world dating from the time of Aristotle, who saw life as showing a trend toward perfection, and even after Darwin, who provided a mechanistic view of biology in his book *On the Origin of Species.* The theory of evolution was supposed to end teleology as an explanation of origin in terms of meeting a future goal or purpose because evolution was seen to be an interaction between random mutation and the process of natural selection favoring differential survival of those individuals with variations that resulted in increased reproductive fitness. In Darwin's theory the mechanism of evolution was seen not as a process having a demonstrable relationship to the future but rather as a consequence of past events and current relationships between the organism and the environment. This outlook does not preclude a philosophical or religious perspective that treats evolution as a teleological process, but such perspectives are not derived from scientific observations that are not informative about whether or not evolution, or the universe, has a purpose.

Evolutionary explanations based on teleological language continue to abound in modern biology in publications ranging from professional research to popular media. This teleological language explains the origin of a particular structure, behavior, or other adaptation as having occurred "in order to" serve its current function—where *function* refers to the contribution a structure gives to the survival of an organism or a species. This function cannot empirically exist without the structure that makes the function possible, and yet the origin of the structure is attributed to that future function. In this context, evolutionary theory uses teleology to explain the origin of biological structure (whether anatomical, physiological, or behavioral) as meeting the requirements of future functions that confer increased survival on the species.

The prominent American Darwinian evolutionist Ernst Mayr claimed that there is now complete consensus among biologists that teleological statements do not imply any conflict with physical or chemical actuality, and the problem of teleology is reduced to the distinction between which teleological statements are legitimate and which are not. It may be argued that teleological language may not require a teleological meaning if it does not endorse unverifiable theological or metaphysical doctrines, attribute physical and chemical properties to biology that are not also applicable to inanimate objects, accept future goals as the cause of current events, or apply human qualities such as intent, purpose, planning, or deliberation to organic structures. Because biological systems behave as if they were teleological (e.g., the maintenance of homeostasis by physiological processes of the cell), teleological language may be unavoidable. It may also be argued that evolutionary biologists are irreducibly involved with teleology because they are in the practice of trying to understand the world with reference to the future when addressing the evolutionary significance of biological structures in terms of their functions.

The principal teleological expression in modern evolutionary biology is the explanation of a structure in terms of its function. This expression is usually in the form of a structure evolving in order to serve or achieve a particular function. For example, feathers evolved as an adaptation for flight. But when it became evident that feathers preceded flight, feathers were understood as an adaptation for some other preexisting function that was later co-opted into a new function. This resulted in evolutionists trying to guess whether an adaptation existed for the existing function or an imagined preexisting function, or whether there is ever any function in the original appearance of the structure or during its subsequent evolution. Evolutionary history becomes a field of imagination where any manner of functions may be invented and somehow explain the origin of the structure, even though such temporal and goal-directed explanations say nothing about the nature of the structure itself.

In preevolutionary biology, natural theology provided a supernatural explanation for teleology. Darwin's argument for natural selection suggested that evolution was a mechanical or physical process that is not organized to meet future goals or purposes. Many early evolutionists, however, continued to view evolution as a teleological process such as the *scala naturae* or "chain of being" where a steady advance was seen to occur through a supernatural force or internal drive toward perfection. This teleological philosophy was also applied to non-Darwinian alternatives to natural selection such as *orthogenesis,* a term used in 1893 by the German evolutionist William Hacke, who recognized that there were evolutionary sequences in complexity in which reversals either did not occur or were rare. As an example, a penguin may become a marine animal, but it remains a bird and does not become a fish. Hacke argued that if any kind of variation could occur, such reversals should be frequent due to those variations being advantageous as some stage. That this was not the case suggested that evolutionary changes may take place that did not owe their origin to environmental selection.

The orthogenetic theory recognized that evolutionary changes were limited to those that were made possible by existing biological structures. This view was supported by a minority of early evolutionary biologists, and it was most explicitly developed and supported as an alternative to Darwinism in the panbiogeographic synthesis of Léon Croizat. In the absence of a biological mechanism for explaining how new mutations may not be random, orthogenesis was characterized by Darwinian evolutionists as mystical and teleological. The teleological restriction for orthogenesis was also seen to be evident in examples from the fossil record that were supposed to demonstrate a linear direction to evolution, with the reduction of toes in horses from the ancestral five to the current single toe as the classic example. This linear concept was contrasted to phylogenetic evidence that evolution was not linear but rather involved a process of diversification or branching. Falsification of linear evolution was consequently a falsification of orthogenesis. This rejection mistakenly conflated two distinct concepts: that of linear evolution and that of orthogenesis. In his original formulation of orthogenesis, Hacke cited the reduction of horse toes from five to one as an illustration of a biologically driven trend, but he did not confine the process to that of a linear or purposeful evolution. Whether or not the historical sequence of horse evolution was "linear" or a branching "bush," there was a reduction of toes that took place over space and time resulting in the single-toed horse of today. Croizat resolved the apparent contradiction between diversification through speciation and the apparent linear sequence implied by orthogenetic sequences by proposing a vicariant form-making model by which characters are heterogeneously distributed over a widespread ancestral range and these geographic variations provide spatially different starting points for subsequent differentiation and speciation. In recent decades new molecular genetic discoveries have also drawn attention to patterns of "concerted evolution" and biological mechanisms of molecular drive, such as biased gene conversion, that result in evolutionary novelty without requiring improved reproductive fitness as a necessary result.

It may be argued that resorting to teleological explanations for the origin of structures in terms of their future function obfuscates the evolutionary process by avoiding the need for causal explanation and a deeper understanding of biological structure. For example, the teleological explanation for the evolution of the leaf as an adaptation for photosynthesis, or the evolution of a feather as an adaptation to flight or insulation, provides no information about the evolutionary origin and structure of the organs themselves. Adaptive, teleological explanations contain no greater information content than purely teleological creationist explanations.

As an empirical science, evolutionary theory can only be neutral about whether or not there is an underlying teleology in the universe and its evolution. Such possibilities are broached from theological or philosophical perspectives but not from science. Teleology remains the most troubling presence of nonscientific thought in modern evolutionary biology that obscures any distinction between a supposedly empirical science of evolution and teleological theories of existence such as intelligent design.

Evolution, Organic

The notion of Darwinian evolution of forms and entities, according to which all organic species descend from a common ancestor through various processes, among which natural selection is the most crucial, forms the framework of current biological investigations. Although biology has undergone deep transformations and conceptual shifts since 1859, the initial formulation of this modern idea of evolution is due to Charles Darwin's *On the Origin of Species.* Darwin promoted a new interpretation of major biological concepts (e.g., adaptation or function) and raised new problems for researchers. The notion of biological evolution entails important consequences regarding the idea of time, especially concerning the time of biological processes and forms, as well as the use of temporal processes in biological explanations.

The first section of this entry sketches the historical context of the rise of evolutionism. The second section explains the major concepts of biological evolution, according to the contemporary version of Darwinism. The third section then focuses on some major controversies that recurrently appeared in the history of evolutionary biology, concerning the process and the pattern of evolution.

History of the Idea of Organic Evolution

The idea of an evolution of species traces back far prior to Darwin. However, Darwin is credited as the father of modern evolutionism because he argued not only for a pattern of descent between species—the *tree of life*—but for a process likely to explain this pattern—*natural selection.* Among prior tenets of what was called transformism, some 18th-century writers (e.g., Jean-Baptiste René Robinet, Benoit de Maillet, and Jean-Baptiste de Lamarck) held versions of evolutionism that explained evolution, yet through rather implausible mechanisms.

Several problems met by naturalists were reasonably stimulating biologists to conceive of a general evolution of species. First of all, whereas big differences among species are obvious, it is not so clear sometimes whether two individuals are of distinct species or of distinct varieties of one species. Therefore lots of classes held to be distinct species, hence distinctively created by God, might turn out to be varieties of one single species. A mechanism would then account for the differences among them. Carolus Linnaeus, author of the most general system of classifying species and proponent of the idea that species were distinctively created by God (fixism), yet faced in this way the problem of hybrids. His contemporary and rival George Buffon defined a concept of species in terms of the ability to interbreed and have fertile offspring, a concept that fared better than a purely morphological concept of species like that of Linnaeus but that was not generally applicable. Moreover, as Immanuel Kant famously explained in the *Critique of Judgment,* naturalists until the 19th century noticed more and more frequently that the types of various species are often quite similar to one another, as if, for example, all the vertebrates were variations on a same theme—what Johann Wolfgang von Goethe called "original type." Étienne Geoffroy Saint-Hilaire in 1820 claimed that whereas the two major orders, vertebrates and arthropods (such as crustaceans), seem absolutely separate (an idea held by his rival Cuvier), they were actually variants of a same type, the arthropod living inside its spine and the vertebrate outside of it. Therefore, several thinkers, particularly from the school of *Naturphilosophie* in 19th-century Germany, conceived of a general evolution of species from the simplest to the most complex forms—though often a logical evolution of forms rather than a historical process—as an explanation of this pattern of similarity.

Religion has obviously been an obstacle to the acceptance of evolution. The Church claimed officially that the earth was only 6,000 years old, which makes a process of transformation of species inconceivable, because at the scale of human civilization no one had witnessed any such change. But this difficulty, which was still precluding Buffon from accepting explicitly the evolution of species (even if he would accept the transformation of varieties) slowly vanished during the 19th century, because, among other reasons, of the discoveries of fossils of unknown animals and of the advancement of geological theories of Earth. Charles Lyell, who was Darwin's friend, wrote *Principles of Geology* (1830–1833), which claimed that Earth could have been shaped several million years ago.

For those reasons, a general audience became more familiar with the ideas of evolution. Just before Darwin, Robert Chambers wrote *Vestiges of the Creation,* a widely read book that sketched a picture of the evolution of organic forms without providing a scientific theory to support it. At the time, philosophers such as Herbert Spencer elaborated general theories of evolution, which in general relied on a formal scheme of complexification. Before him, Lamarckism, the most accomplished transformist theory before Darwin, appealed to two forces: complexification (which explains why, in the same genus, simple forms are likely to give rise to more complex forms) and adaptation to circumstances through inheritance of acquired characters (the latter is generally the version people think of when they refer to Lamarckism).

Evolution by natural selection is one example of simultaneous discovery in the history of science: Darwin, after a long journey on the HMS *Beagle,* came to this idea through reflections on the geographical distribution of species, on morphology, and on domestication, while at the same time naturalist Alfred Wallace had the same idea. This anecdote indicates that in the 1850s the time was ripe for evolutionary theories. Darwin and Wallace presented their results in 1858 in a joint meeting that anticipated the publication of *On the Origin of Species,* which Darwin wrote over several years and published in 1859, before revising it extensively in five successive editions. The book is "one very long argument," and whereas most chapters use arguments from various fields such as embryology, morphology, biogeography, or paleontology to support the idea of evolution by natural selection, several other chapters are devoted to a rebuttal of objections that Darwin foresaw, such as the lack of intermediary forms in the fossil record, complex organs like eyes, and the evolution of instincts.

In general, however, many biologists were convinced by Darwin's demonstration of an evolution of species. The general audience was more reluctant because of religious reasons. However, the fate of Darwinism is more concerned with the reactions to the process hypothesized by Darwin to account for evolution, that is, natural selection. Darwin was indeed pluralist regarding the processes generating evolution; for example, he accepted Lamarckian inheritance of acquired characteristics. The major question then was the relative impact of those several processes on evolution, and this is perhaps the main issue that biologists who followed Darwin have had to address.

What we call Darwinism might have been born when German biologist August Weissmann, working on heredity, conceived of a separation between somatic cells and germinal cells, that is, the characteristics of an individual (and likely to change) and the characteristics that the individual inherited from his or her parents and passed to his or her offspring. This prevents any inheritance of acquired characters and leaves natural selection as the most plausible general mechanism of evolution.

The history of Darwinism in the 20th century means first the modern synthesis, followed by neo-Darwinism in the 1930s. Briefly stated, natural selection, according to Darwin, sorts individuals that vary and have various offspring. The process of selection will occur no matter how the variation is caused, so Darwin's theory was neutral regarding an explanation of hereditary variation (i.e., why all offspring of a couple of zebras are alike, as zebras, and different, as differing to some extent from their parents). But in the 1900s, Mendelian genetics came into play. At first sight, genetics and Darwinism seem at odds, because Darwin was talking of evolution through selection of small differences, whereas genetics treats combinations of discrete characteristics, which seems nongradual. Hence, a controversy opposed Darwinians and Mendelians until the 1920s. Then, Ronald Fisher, Sewall Wright, and J. B. S. Haldane showed that by devising probabilistic models of the evolution of genetic frequencies in populations (a field called population genetics), far from opposing Darwinism, Mendelian heredity is an explanation of heritable variation that makes natural selection necessary and powerful. Mutation of genes and recombination during meiosis and fecundation (in the case of sexual reproduction) provide the variation upon which selection operates. This synthesis between Mendelism and Darwinism is the origin of today's biology. Later, such synthesis was extended to systematics (with Ernst Mayr) and paleontology (with George Simpson). However, the preeminence of population genetics in the modern account of the processes of evolution entailed that evolution is now conceived of as the "change of gene frequencies in a population," whereas the first Darwinians were thinking more loosely, in terms of change of organic forms.

Concepts in Darwinian Evolution

The Concept of Natural Selection

Darwin thought of natural selection as the result of the "struggle for life": Because resources generally are rare in an environment and because the rate of increase of a population generally exceeds the availability of resources (an idea that he famously took from Thomas Malthus's *Essay on the Principle of Population,* 1798), it follows that only the individuals who are better equipped to obtain resources will survive and reproduce, being then likely to pass those abilities to their offspring. The frequency of those traits supporting those abilities increases, and this continued process explains a general change in the species, which finally leads to a novel species (some individuals being so different from the initial ones, or so distant, that they could no longer interbreed with them). More concretely, this competition (mostly between members of the same species) consists in procuring food, escaping predators, and finding sexual partners.

A more abstract formulation of natural selection, less tied to this biological case, can be given. Following Richard Lewontin, any population of individuals satisfying three conditions will undergo natural selection: Those individuals vary regarding some traits (*variation*); they have offspring that vary from them and from one another, in a way that the variation between offspring and the mean of the population positively correlates with the variation between their parents and the mean of the population (*heritability*); and those properties according to which they vary are relevant to the expectation of their having some number of offspring. (If several organisms replicate and vary, but the properties transmitted have no consequences upon their probability of reproduction, there will be no selection at all.) This third property can be called *fitness*. Whereas still intuitive for Darwin when he talked about "survival of the fittest" (following Spencer, and wanting to reject any intentional connotation of the word *selection*), *fitness* is now a technical term that means both survival and expectancy of offspring. Defining the fitness of a trait implies assuming that this trait somehow correlates with the offspring expectancy (Fig. 1).

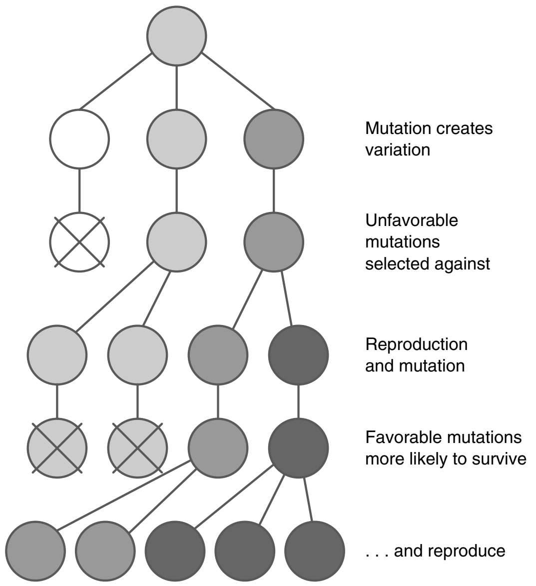

Figure 1 Diagram of a selection process in neo-Darwinism

What the selected individuals really are is not relevant in this formulation. Hence there logically can be selection of organisms, which was what Darwin thought, but also of groups, of species, and, at a lower level, of genes. One of the most debated questions in the philosophy of biology, indeed, is the "units of selection" controversy, namely, the question of what, among those kinds of things, are the ones by which selection takes place. In *Adaptation and Natural Selection* (1966), George Williams argued that selection apparently acting on groups—for example, altruistic behaviors that seem to increase the well-being of the group while threatening the organisms that achieve them—can in fact be explained in terms of selection acting on individuals (organisms or genes). Kin selection, according to William Hamilton, is a selection acting on one gene carried by several individuals: Selection will retain an organism that acts against its "interests" if the consequences can favor one of its kin. On this basis, Richard Dawkins has argued that natural selection indeed acts upon genes rather than organisms. Genes do "replicate"—they are "replicators," in Dawkins's language—but the rate at which genes successfully replicate depends upon the interactions among organisms in terms of reproduction. Philosopher David Hull suggested another formulation of selection: Natural selection is the process according to which replicators differentially reproduce due to the interactions of entities named interactors (in the usual case of biology, it is the organisms). This formulation suggests that natural selection can occur among various objects to the extent that they replicate; for example, Dawkins writes of cultural selection, because cultural entities also seem to replicate.

Explaining Through Natural Selection

The *diversity* of species (in time and in space; e.g., why there are kangaroos in Australia but not in South America) and the *adaptation* of organisms to their environments are explained through Darwinian evolution. First, the taxonomy of species receives a historical interpretation. The only diagram in *On the Origin of Species* (Fig. 2) represents a pattern of branching between species, or genera, or any biological taxa. All the taxonomic relations (being part of the same genus, etc.) were reinterpreted by Darwin in terms of history: The closer two species are in a morphological taxonomy, the closer they are in the temporal sequence of evolution.

The traditional explanation for adaptation referred to the Divine Will or a Providence that would account for the fit between organisms and their environment—for example, the beak of certain species of finches that fits to the depth of the holes within which they chase insects. The Darwinian explanation of adaptation is natural selection: Such a process obviously led to the fit of the beaks with the holes, and in the same time, to the divergence of the Galapagos finches into several species, all being specialized in one kind of hole and characterized by one length of beak. This Darwinian example illustrates how natural selection accounts for both diversification and adaptation of species.

Natural selection provides also a way to escape the suspicion of teleology that constantly assaulted biology. Modern natural sciences exclude explanations in terms of intentions or goals, because by

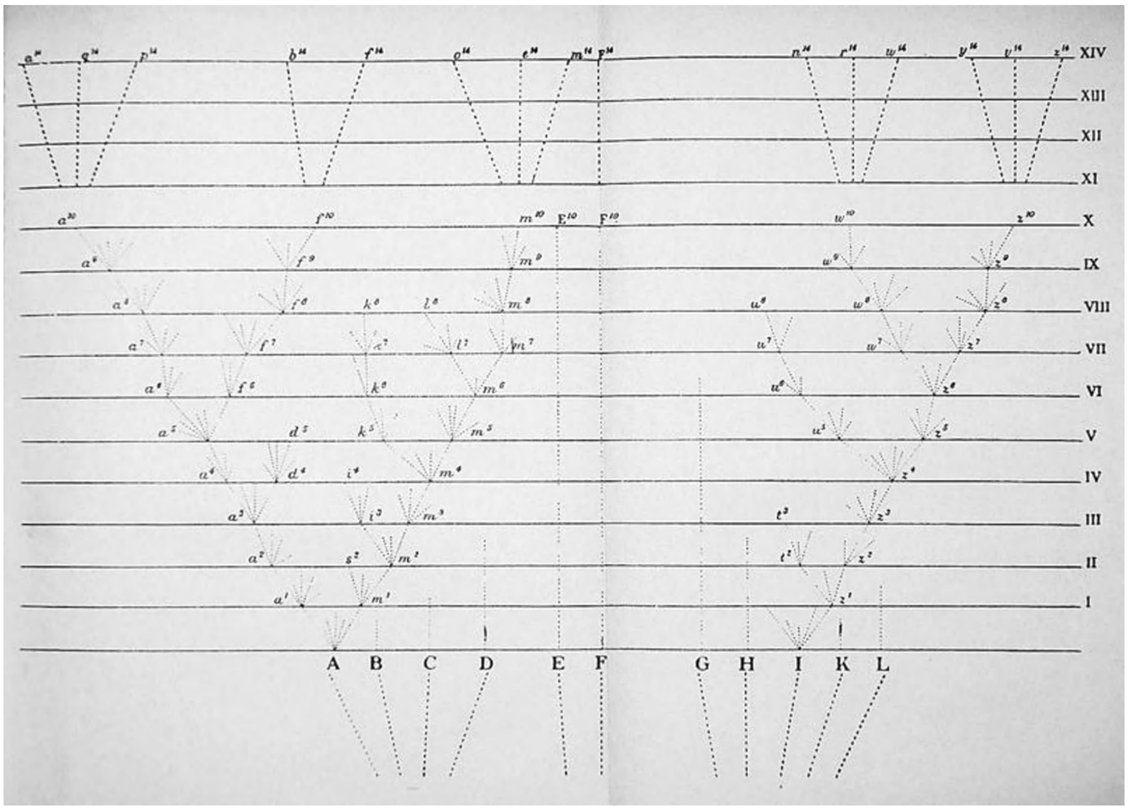

Figure 2 Darwin's diagram of branching evolution

principle nature has no desires. However, talking of *functions* of organic parts means that those parts are here *in order to* do such and such: Such a proposition seems teleological. Although not really embarrassing for biologists, this problem puzzled philosophers of science—especially when funding science for research on concepts in theology was no longer admitted. Kant devoted half of the *Critique of Judgment* to the problem of legitimizing teleological judgments in life sciences without appealing to a Creator. Yet in the Darwinian framework, functional statements do not object to naturalism: philosophers Larry Wright and Ruth Millikan suggested interpreting "the function of X is Z" as "X has been selected because it was doing Z," which does not appeal to any transcendent intention. Natural selection might legitimate the functional talk traditional in biology.

Proximate and Ultimate Causes

The emergence of evolutionism entailed a whole transformation of biology. During the rise of molecular biology, after James Watson and Francis Crick's discovery in 1953 of DNA as the substance of genes, Mayr reflected upon the synthesis to which he contributed. He argued that causal explanations in biology can take two forms: proximate and ultimate. Proximate causes are the processes and events that cause a feature in the life of organisms; for example, the "genetic program" of a certain bird accounts for its migrating behavior, and the physiology of its muscles accounts for the way it flies. Molecular biology, physiology, biochemistry, and embryology unveil proximate causes and constitute what is called functional biology. Evolutionary biology aims at accounting for why the organism is likely to be the way it is; it searches for the evolutionary history that led to the genetic program embodied by the migrating bird. Those ultimate causes extend far prior to the existence of the organisms or species considered. Paleontology, behavioral ecology, ecology, systematics, and population genetics constitute the main disciplines of this evolutionary biology. Mayr added that whereas proximate causes amount to explanations of the same kind as those usually found in physics and chemistry, ultimate causes require another kind of explanation, as they rely mostly on natural selection and have to integrate knowledge of history as a background condition. This of course makes evolutionary biology the core of biology, upon which relies the specificity of biology regarding other natural sciences. This implies that biology has an irreducible historical dimension, contrasting with natural sciences that search for unhistorical laws or correlations, striving only for what philosophers, following Ernst Nagel, call "nomothetic explanations." Moreover, most of the conditions of evolution are themselves products of evolution (e.g., the process of fair meiosis assumed by all the Mendelian rules). The science of organic evolution therefore required that scientific explanation consist also in depicting contingent temporal processes.

Form and Function

In 1916, historian Edward Stuart Russell published *Form and Function,* in which the history of biology is depicted as a fight between two general approaches to living phenomena: a focus on *function* versus a focus on *form*. Those features—forms and functions—are obviously both proper and exclusive to living beings (brute matter does not display transmitted forms). Russell saw the famous debate that opposed Cuvier and Geoffroy Saint-Hilaire at the natural history museum in Paris in 1830 as one major episode in this long-standing debate. Geoffroy, arguing in favor of one general type of organisms realized in all orders, was a tenet of form biology, whereas Cuvier was interested primarily in functions and proposed the principle of "conditions of existence," according to which all functions in an organism must be feasible and compatible. For this reason, because one could not change one function without altering the whole and then making the organism unable to fulfill the principle of conditions of existence, Cuvier opposed Lamarck's gradual transformism. On the other hand, for Geoffroy the general types are fine-tuned only by local adaptations, but their main morphological rules are something universal in the living realm, hence not connected to specificities of the various environments within which various species came to life: For this reason, adaptation cannot account for those rules. The spine, for example, pervasive across all order of organisms, exemplifies such a formal feature.

In *On the Origin of Species,* Darwin considers this debate from the viewpoint of evolution by natural selection. He admits that there are two general principles of biology: conditions of existence (Cuvier) and unity of types (Geoffroy Saint-Hilaire). He inquires into their connection, namely, whether functions of organisms, shaped by natural selection, are the main factors accounting for the various features of the species or whether some general formal features, independent of the successive environments of organisms but historically transmitted, are the major constraints on the history of life. He answers that the principle of the conditions of existence redounds to natural selection, whereas unity of type specifies the stable persistence of organic forms. However, because those inherited forms are themselves constituted through evolution by natural selection, those types in the end rely on the action of natural selection and the unity of type gets subsumed under the conditions of existence principle. This means that Darwinian biology subordinates form biology to function biology.

Major Long-Standing Issues in Evolutionary Biology

Issues Relevant to the Process of Evolution

Even if selection is acknowledged as one of the main causes of evolution—Lamarckian evolution being excluded—other mechanisms have been conceived of by biologists. One classical formulation of the question of evolution in population genetics is analogous to mechanics, as argued by philosopher Elliott Sober in his 1984 work *The Nature of Selection*. Considering some varying traits in a population, geneticists first write the equations that would rule the change of gene frequencies in a pure Mendelian case with no selection, no mutation, and no migration—this is called the Hardy–Weinberg equilibrium. Then they compare it to the actual case. Any deviation from the expected equilibrium frequencies should have a cause, possibly natural selection. Yet, Sewall Wright in the 1930s showed that in small populations, a sampling error occurs that can lead to the fixation of some genes independently of their selective value. This “random drift” would disappear in infinite populations, but because real populations are always bounded, random drift surely matters in the actual evolution of gene frequencies.

Thus apportioning the causes of evolution, especially selection and drift, is a constant problem faced by population geneticists. Several important controversies in the course of evolutionary biology revolved around such issues. At the origin of the modern evolutionary synthesis, Ronald Fisher argued against Wright about the role of drift. If drift is important, as claimed Wright, then the mean fitness of populations is not always maximized, whereas Fisher opposed a mathematical formula he proved, the “fundamental theorem of natural selection,” meaning that the mean fitness necessarily increases until genetic variance is exhausted. Deciding this point implies an empirical knowledge of the size of natural populations. Later, the question involved an investigation of the reasons of genetic variability—polymorphisms—in populations. Biologists such as Theodosius Dobzhanski and Hermann Müller, among others, forged theories to account for this maintenance. Later, Motoo Kimura vindicated the so-called neutralist theory of evolution, claiming that most evolution at the level of nucleotides (the molecules composing the DNA) is neutral, due to drift, because most of the mutations of nucleotides are selectively neither advantageous nor deleterious. Although theoretically important, this theory does not truly oppose Darwinism because it is concerned only with the molecular level and leaves intact the idea that the evolution of genes themselves and of phenotypes is due to selection. However, the neutralist theory emphasized that evolution is a constant process occurring at many levels and according to various mechanisms.

It is often difficult to consider the evolution of one population of one species, because the ecological fates of several species are tied—each one defining selective pressure for the others. Cases of parasitism and of mutualism (e.g., between figs and wasps, ants and plants, humans and intestinal bacteria) belong to a general study of co-evolution, which accounts for innumerable features of the organic world.

Other important controversies arise when we turn our gaze from microevolution, which concerns rather short timescales and relatively unmodified environments, to macroevolution, or evolution at a higher level, concerning, for example, the appearance of new classes of organisms. It has been debated since the founding fathers of the modern synthesis whether macroevolution is microevolution at a larger scale or whether it requires novel principles. Simpson and Mayr defended the former position, because they thought that an appeal to novel principles (e.g., macromutations) would threaten Darwinism. Biologists such as Stephen Jay Gould, Niles Eldredge, Elisabeth Vrba, and Sean Rice consider natural selection of species, in which case the properties selected (e.g., the geographic range of a species; the genetic variability) are properties of the species itself, unlike the mechanisms accounting for microevolution, all of which have to do with traits of individuals.

But the main challenges concerning this question of macroevolution came recently from the evolutionary theory of development, or Evo-Devo. In microevolution, natural selection shaping adaptations for some functions is plausibly the main cause of evolution. This exemplifies the Darwinian bias in favor of function biology. However, in *The Changing Role of the Embryo in Evolutionary Biology* (2005), Ron Amundson argues that the adherents of form biology constantly opposed this Darwinian demonstration of the supremacy of function biology. Their challenge gets more consistent because they invoked some novel style of laws of forms that scientific investigation has been pinpointing for 3 decades. Briefly said, neo-Darwinians thought that mutation (and recombination) forms the material for natural selection. They separated two ideas traditionally joined: inheritance (i.e., transmission of characters from parents to offspring) and development (i.e., the ontogenetic process of an individual). Selection acts on traits, no matter the process through which the individual came to display those traits, so development seemed relatively external to evolution. Yet, some developmental theorists emphasized that development can both constrain and provide variations by changing the rhythm or order of the process, as Gould summarized in his classic 1977 work *Ontogeny and Phylogeny.* Evo-Devo researchers contend that the changes relevant to macroevolution, for example, key innovations like the wings of insects, or the thermoregulation system of mammals, involve the effect of developmental constraints and are not understandable solely as effects of natural selection acting on punctual mutations in the DNA. (But for them evolutionary theory is therefore more concerned with explaining across-taxa features, like the vertebrate limb, rather than change within taxa and thus adaptations.) This debate is obviously related to the set of problems posed by the understanding of the phylogenetic pattern in general.

Issues Relevant to the Pattern of Evolution

The tree of life raises three types of questions, all crucial to current evolutionary biology: the shape of evolution, its orientation, and finally its origins.

Gradualism and Discontinuities

For Darwin, evolution of the species was a gradual branching process. Neo-Darwinism emphasized gradualism, as variation would rely on small mutations. For this reason, neo-Darwinists have constantly been puzzled by discontinuous evolution, for example, key innovations. In the 1970s, paleontologists such as Gould and Eldredge challenged the general gradual view of phylogeny, arguing that changes in evolution display a discontinuous pattern: a fast (at the geological timescale) burst of novelty and a very long period of stasis, with only minor modifications possibly due to adaptation to local conditions. This theory of punctuated equilibria, albeit neutral regarding the mechanisms of evolution, fits with theories from Evo-Devo (held by Gould), which contrast very big changes relying on transformations in developmental processes with minor changes due to selection on point mutations. This issue rests mostly on the interpretation of the fossil record: Darwin claimed that its lack of transitional forms was due to geological reasons, whereas adherents of punctuated equilibria claim that the record is, as such, quite reliable and constitutes evidence for the stasis–burst schema of macroevolution. In this case, macroevolution would not be easily reducible to mechanisms of microevolution, and neo-Darwinism in general—since its core is population genetics—would have to be qualified. The emergence of the most general plans of organization (e.g., the one taking place in the Cambrian and explaining most of the extant phyla) is not accountable solely on the basis of micro-evolutionary principles.

In 1995, John Maynard Smith and Eors Szathmary initiated a theory of the major evolutionary transitions. Those are the fundamental events in evolution, through which the forms of inheritance and replication changed. Replicating macromolecules, single cells, multicellular organisms, social organisms, and organisms with language are the steps of this evolution. Each time, natural selection both contributes to the transition and becomes changed through it, because new selectable entities arise. In this perspective, evolution by natural selection is not absolutely tied to genes or life, and extends from molecule to talking beings. Such a globalized theory casts a new light on the problems of discontinuity in the mere history of life. Cooperation between entities (e.g., genes in chromosomes or insects in colonies) is a pervasive pattern of explanation of those transitions and requires understanding how natural selection could favor cooperative behaviors while selfish defection would be at first sight selected for.

Direction

A common view of evolution sees it as oriented toward greater perfection and achievement. Yet this is precluded by the very logic of Darwinism, for which natural selection optimizes populations regarding their environments—hence, two organisms of two different species, belonging to different environments, cannot be compared or considered as stages of a continuous improvement. At the same time, it is difficult not to notice in a given branch of the tree of life (e.g., the vertebrates or the mollusks) trends of increasing complexity: diversification of functions, finessing of detecting devices, increase of some quantities related to the size of genes, and so forth. Darwin was ambiguous regarding this issue: Although he opposed the notion of absolute perfection, he was led by common intuitions about progress in evolution. The major conceptual issue, however, is still to figure out a concept of complexity likely to capture those contrasted intuitions. Biologist Dan McShea has shown in recent papers that a "complexity" thought in pure formal terms (diversity of parts with no functional considerations) makes visible some phylogenic trends in increasing complexity. This notion is yet far from the intuitive one, and it seems, then, that no theory could decipher in the history of life this constant progress culminating in human species.

Origin

Evolution by natural selection commits one to say, like Darwin, that all forms of life came from one single organism (a position that irritated the defenders of religious orthodoxy). The fact that all species share elements of the same genetic code provides more evidence of this single evolutionary history. From a Darwinian viewpoint, the issue is the genesis of an entity satisfying the conditions of natural selection. This problem involves both chemists and paleontologists—people seeking traces of what happened and people conceiving processes that could have happened. Within evolutionism, questions of origin are crucial: origin of sexual reproduction (why humans pass on only 50% of their genes to the next generation, whereas organisms that reproduce asexually pass on 100%), origin of mind and of culture. Whereas no theory is completely satisfying, natural selection clearly plays a fundamental role in those events.

Evolution, Social

Social evolution is regarded as a particular form of general evolutionary process that occurred in communities of the genus *Homo* (or, more narrowly, in communities of anatomically modern humans). It implies changes over time of different forms of relationships among human beings (individuals and their group) that are inwardly connected and interdependent and have given rise to new social forms and connections.

Chronologically, the concept of social evolution applies to the process of origin and change in social organizations and social complexity, which is associated with structural changes in human society. It is difficult, however, to distinguish properly the social form of evolution from political, cultural, and other forms of nonbiological evolutionary processes, just as it is practically impossible to distinguish between social evolution and social development.

Social Evolution in 19th- and Early 20th-Century Anthropological Thought

Early ideas about social evolution were expressed in the works of ancient Greek philosophers such as Democritus and Aristotle; such ideas were disseminated more widely in the early medieval period on the basis of Saint Augustine of Hippo's Christian concept of sacral history. The Enlightenment brought new insight into social evolution, with multidimensional analyses of social changes framed in terms of the natural evolution of the world. In such a context, social evolution was identified with progress, which was understood as the gradual perfection of society, realized on the basis of humankind's spiritual emancipation. In the modern era, social evolution has been interpreted by Georg Wilhelm Friedrich Hegel, Karl Marx, and followers as a process determined by its primordial essence. The closest analogy to such an understanding of society's changes in time may be found in the life of a plant, which grows from a particular seed. Sometimes it takes a final form implying the preexistence of a certain final stage of evolution (as in different forms of utopias). Nevertheless, in terms of a teleological understanding of social evolution, the problem of the origin of new forms of social life remained unattended.

The tendency to conceptualize human history in a framework of gradual development that implies improvement of an already existing substance or the origin of new ones has occupied the attention of scientists and the public since the 1870s when Charles Darwin's *On the Origin of Species* was published. The concept of social evolution as directional and irreversible linear change became an integral part of the scientific discussions of that time, and it is not surprising that in seeking to explain its driving forces, anthropologists refer to mechanisms in biology.

The earliest application of evolutionary ideas to the study of human society, and the origin of the organic school in sociology, is traditionally ascribed to the work of Herbert Spencer, who managed to synthesize the embryology of Karl Ernst Ritter von Baer, the geological theories of Charles Lyell, the physical law of conservation of energy, and the ideas of Charles Darwin. According to Spencer, social evolution is a permanent redistribution of elements in their movements toward integration and disintegration, thereby creating some kind of equilibrium. Social dynamics was understood by Spencer as the progressive transition of a society from homogeneity to heterogeneity, or its differentiation. He distinguished four evolutionary types of human society (simple, compound, doubly compound, and trebly compound), which could range from politically nondifferentiated (egalitarian) primitive societies to complex civilizations. Survival of the most adapted industrial societies based on positive knowledge he considered the basic law of social development. Spencer's views created a background for social Darwinism, an ideological trend in social thought, widespread at the turn of the 20th century, that advocated for a reform of human social development according to laws of biological evolution. Competition, natural selection, the struggle for existence, and survival of the most adaptive individuals were recognized by social Darwinists as the basic determinants of social life.

Nevertheless, most early evolutionists did not share the view that different stereotypes of social behavior reflect different stages of historical development, and in frames of their peculiar field of study tried to illustrate social progress with the help of pertinent cultural phenomena. McLennan, Maine, Robertson Smith, and others studying common law, marriage, and kinship systems helped to promote the Stadialist hypothesis about social development by stages. In their understanding, these stages are universal, and the diversity of social institutions is the outcome of specific contingencies in the life history of certain groups.

For the first time, such ideas were shaped into strict schemes of human history periodization by Lewis Henry Morgan in his *Ancient Society* (1877). According to Morgan, human history could be subdivided into two global phases: The first one—*societas*—was characterized by social organization based on kinship, fraternity, and tribes and demonstrates egalitarianism, whereas the second—*civitas*—was represented by political organization based on different attitudes of humans to territory and property and was characterized by social and economic inequalities.

A different approach to social evolution was elaborated at the end of 19th century by Karl Marx and Friedrich Engels, whose basic point was the concept of the evolution of modes of production, understood as a concatenation of productive forces (often identified with technology) and relations that are practiced in the course of production (in most aspects determined by the ownership of productive forces). Against this background they distinguished four stages of societal development: primitive, slavery, feudal, and capitalist (*German Ideology,* 1847). Later, Engels, in his *Origin of Family, Private Property, and the State* (1884), based on detailed studies of Morgan's *Ancient Society,* worked out in detail the periodization of human history and interrogated the final period of prehistory (later called the "war democracy stage") when private property, classes, and the state arose. He demonstrated that the origin of the state, characterized by such traits as authorities estranged from the wider public, the taxation system, and so on, is the result of society's internal subdivision into classes.

Under the influence of Marx and Engels, the "stadialistic" scheme of social evolution, based on economic determinism, became widespread in Soviet academic life. During the period 1929 to 1934 on the basis of Engels's work, a general understanding of historical process as the dialectic replacement of one form of economy by another, more progressive one resulted in the elaboration of a five-component scheme of social and economic structures (Marx's four plus communism, grounded by Vladimir Ilich Lenin), which was proclaimed the only officially approved explanation of social evolution.

A gradual decrease in the popularity and reliability of evolutionism as the universal foundation of cognitive and interpretative methodology, and a tendency after World War II to replace it by functional and structural analysis and by historical, geographic, psychological, and sociological comparativistics, have led to a partial revision and shaping of neo-evolutionism as a self-sufficient methodological approach. Its proponents (V. Gordon Childe, Leslie A. White, Julian Steward, Marshal Sahlins, and others) had serious doubts about the possibility of global unilinear progress in culture and technology, arguing for plurality of historical process and its driving forces.

Stages of Social Evolution: Neo-Evolutionistic Approach

The stadial scheme *band—tribe—chiefdom—state,* outlined in brief by Marshal Sahlins in

1960, worked out in detail by Elman Service in 1962–1971, and further elaborated by Joseph Marino, is in a sense a restitution of the unilinear evolutionary scheme. In proposed consequence every stage could be described by a set of social, economic, and political parameters that demonstrate correlations with a certain chronological span. At the same time, Service implied that new social and political forms are strictly functional ones, and their evolution fits new needs of evolving communities. In such a context, social complexity could be viewed as an adaptive response to challenges to human survival. In contrast to Steward's and Service's adaptationist understanding of social evolution, proponents of the so-called political approach to detection of the driving forces of leadership shaping argue that central power results from expanding domination and necessity to control rather than the management of the economy for the benefit of an elite. This view is connected with the further development of Marxist ideas and is reflected in the particular view of social complexity formation elaborated by Robert Carneiro.

Band societies, or the family level of social organization, traditionally exemplified by leaderless egalitarian communities of prehistoric and contemporary hunter-gatherers, represent the simplest level of social complexity. The only principle of community leader choice is his or her personal qualities and abilities (primitive form of so-called meritocracy principle); in the case of nonsufficient management, administration, or both, the leader could be replaced immediately. Recent studies indicate that the gender attribution of the leader is not a decisive factor in leader choice and function delineation. At the same time, some hunter-gatherers (e.g., Australian aborigines) practice a form of nonegalitarian community with a tendency to concentrate power in a close group of elders who are organized hierarchically.

Tribal (or segmentary) society stage, or "local group" form of social complexity, usually is ascribed to the community with signs of so-called prestigious economy, which implies the presence of surplus product based on hunter-gatherers as well as productive economy. These social structures are characterized mainly by high territoriality and fragmentariness insofar as their main units—villages—tend to be self-sufficient economically but at the same time tending toward political, social, and ritual agglomeration.

Chiefdom and its conceptualization is one of the most widely discussed issues in contemporary social and political anthropology. Usually it is defined as a social organism consisting of group of villages (communities) organized hierarchically and subordinated to the central, biggest among them, where the chief (ruler) is living. The functions of the chief include organization of the economy, including procurement and redistribution; regulation of judicial and mediatory processes; and supervision of the social unit's religious and cultural life. In exercising power the chief could rely on rudimentary bodies represented in all territorial segments of the chiefdom. According to R. Carneiro, chiefdom structure is the first experience of political hierarchy introduced into local communities' networks and entailing loss of autonomy. At the same time, the endogamous elite of society had no monopoly over the application of force in the case of weakening of their control over the group. Usually the supreme power is sacralized or even theocratized, and chiefdom as a whole is characterized by common ideology and rituals. A. Johnson and T. Earle distinguish between simple chiefdoms, which include perhaps a thousand people with modest social differentiation, and complex chiefdoms, which engage tens of thousands of hierarchically organized people. The earliest signs of chiefdoms in Europe usually are traced back to the transition from Neolithic to Eneolithic period (about 5000 BCE) when primitive forms of town (protected settlements) spring up alongside ordinary settlements; origin of megalithic constructions, stratified burials, separation of special ceremonial places usually are connected with that time. During the Bronze Age these phenomena gradually became common for the whole ecumene.

The *state* phase of social complexity formation is characterized by internal differentiation by class, tightly connected with the origin of private property and exploitation; by high centralization maintained with the help of military, religious, and bureaucratic administration; and by the origin of ethnicity. Among other important traits of the state, record keeping, highly developed transportation and communication means, and the use of written language for civil and criminal law codification are usually mentioned. The most recent trend in the conceptualization of state origins is connected with the distinction of the so-called early state phase, characterized by nonstable relations and transferable status of classes, and by an ill-defined position of administration owing to a nonfixed legislation system, which is in the process of transition from common law to codified written form. Traditionally the earliest states are found in the Near Eastern zone (famous cities of Mesopotamia) and Ancient Egypt. Attribution of the ancient Greek *polis* to that phase remains disputable.

This stadial scheme, in spite of its imposing restrictions on the cultural and economic variability of human societies in time and space, had by the mid-20th century contributed greatly to the systematization of an impressive database collected by archaeologists and ethnographers. In the late 1980s it was brought into correspondence with a new database by A. Johnson and T. Earle and, since that time, has remained one of the most widespread in Western and former Soviet Union anthropology schemes dealing with issues of the origins of social complexity. Currently it is competing well in distinguishing among egalitarian, rank, and stratified society as the main evolutionary stages of social complexity evolution in prehistory, proposed in 1967 by M. H. Fried and based on the dynamics of social inequality.

Multilinear Social Evolution: Contemporary Theories and Hypotheses

Traditionally, the origin of the multilineal version of cultural evolution is associated with Steward, who in the context of rapid development of neoevolutionism in the mid-20th century had proposed the concept of *multilinear evolution,* with special emphasis on plurality of social development (*Theory of Culture Change,* 1955). An important cornerstone in this context also was proposed by Sahlins and his distinction between general and specific evolution (1960), which opened wider perspectives for a pluralistic interpretation of the global history of humankind and human culture.

Nevertheless, the roots of multilineal understanding of social evolution could be traced back to 1857–1861, when Marx distinguished three social and economic forms preceding capitalism—Asian, Antique, German—each of which could be interpreted as independent versions of the transition to state organization. Later, Engels (1878) suggested two forms of state origin (Eastern and Antique). Engels understood pluralistically not only lines of evolution but also the background of the process itself. Engels's "enigma" is widely discussed in the context of neo-Marxism, along with the well-known private property–based class theory of state origin, explained in detail in *Origin of Family, State and Private Property* (1884). In other works (e.g., *Anti-Dühring,* 1876–1877), Engels used a functional version of the explanation of state formation consonant with that of Marx.

These multilineal ideas, maintained since the very beginning by representatives of so-called intellectual Marxism (e.g., K. Vittfogel, N. Plekhanov), were later creatively developed by representatives of Soviet science and Western neoevolutionism. In this context, Soviet science emphasis was shifted toward detection of differences between "eastern" (or state property–based) and "western" (or private property–based) lines of social development (Yu. Pavlenko, G. Kiselev, K. Morrison, A. Southall).

Some researchers interpret Asian and Antique lines of state formation as dead-end versions of social development, with the Antique going no farther than a slave-owning system; only the German line managed to give birth to a feudal economy and, later, the capitalist society of the modern era. The final third of 20th century brought to light a "Slavonic" line of state formation and further social development connected with impetuous administration and bureaucracy development and a "nomadic" version of social, political, and cultural evolution characterized not only by unique forms of economy and livelihood but also by a relatively high level of aggression.

In the 1970s, a shift toward environmentalism in anthropological thought brought into researchers' view the ecological situation, which could stimulate or impede social transformations. This idea, based mainly on Steward's assumption about the adaptive abilities of economic systems, was later developed in a series of models that included such variables as climatic risk and resource base diversity. Certain fundamental ideas were proposed by Marvin Harris (1977, 1979), who believed that social evolution is provoked by an inherent human tendency to suffer eventual depletions in living standards that, in their turn, result from population pressure and environmental degradation.

The subject of social evolution remained a focus during the entire 20th century. In contrast to most of the aforementioned theories of social evolution, Max Weber suggested that the subject could not be identified with society itself—rather, it is a mere abstraction, arising from individuals who are evolving in the context of a certain value system. His idea has become a background for the elaboration of typological, psychological, and culturally anthropological approaches to social evolution conceptualized through interaction of cultural and social systems, in which individual motivation is conditioned by values (patterns) of particular cultures, and each social system determines the realization of motives. In this context the principal source of social evolution could be found in world models elaborated by human beings; such world models determine ways in which individuals realize their interests in the course of social evolution, trying to find problem solutions (i.e., world rescue) through the introduction of innovations in all spheres of human life, sometimes creating new problems and threats.

Existentialism

Defining existentialism as a philosophy is notoriously difficult, primarily because it embraces several philosophical positions, many of which conflict. Yet, existentialism can be generally defined as a reaction against traditional philosophy's emphasis on the abstract, the objective, and the rational; instead it emphasizes the dynamic, the subjective, and the personal. Emphasizing personal involvement, engagement, choice, and commitment, existentialism is concerned with the existential, feeling, thinking individual who makes decisions and acts from a particular life situation rather than from a universal position determined by reason, history, or time. Existentialists advocate choosing an *authentic* life: a life not attained through social norms and everyday expectations but rather through the individual's own choice, engagement, and self-creation. Consequently, abstractions and generalizations are avoided on the basis that each individual should choose and create his or her own nature. This radical freedom, checked only by death, which defines the limits of existence, and personal responsibility leads to the feelings of despair, boredom, and alienation popularly associated with existentialism. Thus at its core, existentialism is the study of problems of existence and questions of being. Questions of time—how the individual exists within the present and relates to the past and future—are central to many existentialist philosophers' questioning of being.

As an intellectual, literary, and cultural movement of the late 19th and early 20th centuries, existentialism is largely identified with the French intellectual Jean-Paul Sartre. The major intellectual precursors of the movement are varied but are found primarily in the work of 19th-century Danish religious thinker Søren Aabye Kierkegaard, German philosopher Friedrich Nietzsche, and Russian novelist Fyodor M. Dostoyevsky. A few major philosophers identified as existentialists include Martin Heidegger, Karl Jaspers, Martin Buber, Maurice Merleau-Ponty, Gabriel Marcel, and Miguel de Unamuno y Jugo. However, many, most notably Albert Camus and Martin Heidegger, rejected the label, in part to avoid generalization and group classification. As a cultural and literary movement, existentialism flourished in Europe in the 1940s and 1950s, largely under the directive of Jean-Paul Sartre, Simone de Beauvoir, and Albert Camus.

Heidegger and Sartre

Concerning issues of time, two of the most important existentialist writers are Heidegger and Sartre. Yet, their differing conceptions of the power of the moment and its relation to time, as well as of individual freedom and choice, led them to differing theories of time. In *Being and Time* (1927), one of the most influential existential works published before World War II, Heidegger proposed a new conception of our relation to time and history. For Heidegger, existence is always historical. Rather than view time as a sequence of moments, he argued that human existence must be understood from three units of existential time: past, present, and future. Existential time is a unified structure in which the future recalls the past and gives meaning to the present. Existence, then, is more than just being present in a series of temporal moments; it is the orientation of oneself within the unity of a history. He further argued that while choice belongs to a moment, it is not limited to the moment. Thus, to lead an authentic life, the individual must understand choice within a historical framework. For Heidegger, human choice is always within the context of the past, present, and future, and therefore within the context of meanings and agendas that did not originate with the individual and so cannot be eliminated. The freedom to make choices, then, does not allow individuals the ability to escape their historical contexts. Rather, the freedom of choice allows humans the opportunity to create responses that have the potential to generate unexpected possibilities within their given context.

Whereas Heidegger argued that existence is historical and that individual freedom and choice are informed and checked by a historical context, Sartre argued a strikingly different position on being and history that was originally formulated in one of his best-known philosophical works, *Being and Nothingness* (1943). Sartre viewed history as the foundational situation in which the individual makes choices and the process of self-making occurs. His understanding of the individual's position in time is largely informed by his theories on meaning, freedom, and choice. For Sartre, the individual's only source of meaning is freedom—more specifically, freedom of choice. All things and beings, including humans, acquire meaning through human projection. Because that projection is totally free and not conditioned by the past, individuals are defined only by how they choose to define themselves. This open freedom allows individuals to completely control the meaning in their lives and thus to control the meaning of the past, present, and future. Individuals, then, are solely responsible for the future. Sartre argued that individuals fear this open freedom and responsibility and cling to rigid self- and social definitions. He demanded that human individuals recognize this freedom and act decisively in an otherwise inherently meaningless world.

Together Heidegger and Sartre raise questions about how the future is linked to the past and how the present is constructed. Both recognize that the past does not simply continue unguided, and both argue that the influence of the past is propelled by human freedom and choice. For Sartre, freedom of choice provides humans the agency to control the meaning of the past. For Heidegger, freedom of choice provides humans the agency to overcome the past. In addition, both reject the idea that rational analysis of the past can guide future values. For Heidegger, human choice is always contained within a framework of meanings and contexts that can be creatively reformed and manipulated to generate new possibilities. For Sartre, human choice is always separated from the past through a moment of indeterminate freedom: The individual is always granted the freedom to choose what past to propel, and in doing so, to shape the present and the future anew.

Nietzsche

Whereas Heidegger and Sartre dealt with conventional views of time divided into past, present, and future, other existentialist writers—namely, their precursor Friedrich Nietzsche—adopted a cyclical view of time. Throughout his writing, though most notably in *The Gay Science: With a Prelude in Rhymes and an Appendix of Songs* (1882) and *Thus Spake Zarathustra* (published in four parts between 1883 and 1892), Nietzsche advocated a revival of the ancient concept of time as "eternal recurrence," wherein time repeats itself cyclically and one's life is lived over and over again. The cyclical nature of time bestows the individual with an enormous responsibility, and the way that one lives life becomes crucial. Nietzsche's conception of time placed significant importance on questions of being and existence, as well as the significance of the choices one makes in life. Nietzsche's premise is most notably dealt with by the 20th-century writer Milan Kundera in his novel *The Unbearable Lightness of Being* (1984).

Conclusion

At the core of existentialism's questioning of being is the questioning of time: What will humans choose to become? How much freedom and choice do humans have in relation to the past, to the present, and to the future? For most existentialists, freedom of choice and the ability to make authentic choices allow humans agency in carrying on the past, negotiating the present, and directing the future.

Experiments, Thought

Because we are not always able to carry out physical experiments to learn more about our world, scientists, philosophers, and others use thought experiments. This type of experiment is a way to use the imagination to investigate puzzles and new theories. Anyone can conduct thought experiments. All that is needed is to conceive of some problem or question, imagine in your mind how it might be tested or resolved, develop in your mind a method to do this, and rationalize what the results might be and how these results would affect the real world.

By no means are all thought experiments confined to scientific areas. They are used in philosophical arguments, in discussions about ethics and morals, and in other areas. Sometimes they are used to disprove preexisting theories and sometimes to advance new theories.

Thought experiments are nothing new—they were carried out by thinkers more than 2,000 years ago. A very early experiment, known as "Lucretius' Spear," is described in his poem *De Rerum Naturam* ("On the Nature of Things"). Lucretius used the technique in thinking about the nature of space. He described what might happen if one could carry a heavy spear to the edge of the universe and then hurl it forward. Only two results seem possible: Either the spear would keep going, in which case obviously there was something beyond the edge, or the spear would be stopped at the boundary. If there were indeed a boundary, then what was outside the boundary? In either result, space must be infinite.

Other Greek philosophers, such as Ptolemy, Plato, Socrates, and Aristotle, all used what we now call thought experiments. Some of the most important were created during the Renaissance, when thinkers such as Galileo Galilei, René Descartes, and Isaac Newton used them to develop principles still important today.

Newton, in his Newton's Bucket experiment, argued for the existence of absolute space and absolute motion. In other words, he attempted to show that space and motion are not dependent on anything else. If all matter in the universe were removed, space and motion would still exist because they do not depend on anything outside of themselves.

Newton's Bucket described an imaginary experiment in which a bucket is filled partway with water and then suspended by a rope from an overhead rafter. The bucket is then turned around and around until the rope is tightly wound. At this point, the water is perfectly level. However, when the bucket is released, it begins to spin. As it spins faster, just as water stirred in a cup gradually begins to rise around the edges and sink in the center, so too would the water in the bucket act.

At the beginning, while the water was level but the bucket had just begun spinning, there was a relative relationship between the water and the bucket. As the speed increases, even though the bucket and water are moving at the same speed, the level of the water changes. Newton felt this proved that the level of the water did not depend on the motion of the bucket; therefore space and motion were not in a relative relationship. Later thinking about space, time, and motion brought this idea into question.

A thought experiment by Albert Einstein dealt in a way with the questions of absolute motion or rest. Einstein described a magnet and a spiral wire. We know that a magnet next to a wire can create an electrical current. He imagined what would happen if the magnet were at absolute rest (assuming there is such a thing). The wire, because of its proximity, would develop an electric current. If the wire is stationary and the magnet moves, there would still be a current induced in the wire. Finally, if both were moving relative to each other, the induced current still would be created. These and other Einstein thought experiments all fed into his special theory of relativity, the first principle of which is that the speed of light is the same for all observers no matter what their position is in relation to the origin of the light source.

Anticipating concepts of relativity by more than 400 years was Giordano Bruno (1548–1600). In several thought experiments Bruno expounded relativistic concepts. For example, in the Argument of the Third Dialogue of his *De l'infinito universo et mondi* (*On the Infinite Universe and Worlds*), Bruno noted that looking down from a mountain on a sea on a bright night, we would see the whole sea illuminated. However, afloat on the sea at the same time, we would just see a small bright area near us.

Closely allied to these mental experiments are counterfactuals, which are used in many subject areas as well as in speculative fiction, sometimes called alternative history. Counterfactuals spring from taking a significant event in history and imagining what the world might be like had the event not happened. What if the Great Wall of China had never been built? Would the constant barbarian invasions have prevented developments in China that later influenced the West? In the United States, what if the South had won the Civil War?

Historiographers may use thought experiments to explore the development of various schools of political thought, such as Marxism. Social and public policy questions can draw on these techniques to try to shed light on moral and ethical questions such as abortion. A moral philosopher named Judith Jarvis Thompson set up the "Famous Violinist Problem." This experiment describes a situation where an individual is kidnapped. This individual's internal organs are linked to a world-famous violinist whose organs have failed and will die unless saved by this operation. By staying on this support for 9 months, the violinist will recover and survive. If disconnected before 9 months, the violinist will die and all the great performances that might have been will never take place. Do the perpetrators have a moral right to take such an action?

Today few scientists deny the usefulness of thought experiments. In fields such as philosophy, ethics, and linguistics, some thinkers raise questions about the validity of this way of thinking. These objections range from concerns about their impracticality, overreliance on intuition, divorcement from reality, to the tendency toward oversimplification of complex issues. However, when looking at the long list of scientific advances spurred by these experiments, it is difficult to deny their importance.

Extinction

The process of evolution allows for extinction in that the survival of the fittest tends to assist in population growth and diversity but extinguishes the weak. By extension or analogy, extinctions related to the evolutionary process affect not only plants and animals but culture as well, and all that it entails. In 1846, Justus Liebig observed that the success of a population or community is dependent upon an intricate complex of environmental conditions and that any condition that approaches or exceeds the limit of tolerance for the organism or population in question may be said to be a controlling factor. By exceeding the limits of tolerance, extinction can occur with innovations, inventions, communications, ethnicities, languages, economies, and civilizations. The Stanley Steamer became extinct when the internal combustion engine gained in popularity early in the 20th century. What ever became of the 13-key Marchant calculator so popular with statisticians in the 1950s? For that matter, how many communicate in Latin anymore? There were societal things that now no longer exist, or are no longer active, or have gone out of use, or have become ineffective: The incandescent lightbulb, so ubiquitous today, may become extinct in the 21st century as more energy-efficient alternatives become available to a world increasingly concerned with dwindling energy supplies.

During the past couple of billion years, life has evolved from simple one-celled creatures, such as the amoeba, into complicated complex multicellular life forms or living environments. Along the way, several mass extinction events have occurred. One of the two largest mass extinctions was caused by the breakup of Pangea at the end of the Paleozoic era, known as the Great Dying, when about 90% of all marine species and 75% of all land animals became extinct. The other was at the end of the Mesozoic era, when massive igneous eruptions and the impact of a great meteor created a highly toxic planetary environment, resulting in the extinction of about 75% of all marine species and, on land, the total extinction of the dinosaurs. The limit of tolerance was definitely exceeded in both cases.

In the past 500 million years there have been at least five or six major extinction events, and about the same number of smaller ones. A variety of conditions, including igneous (volcanic) eruptions and meteorites, have contributed to these extinction events. Toxic gases entering the atmosphere from extensive igneous eruptions, resulting in acid rain and acid deposition, have the ability to kill plant and animal species. This has occurred historically and is also taking place at the present time. Then, too, global cooling and global warming have resulted in extinctions by merely exceeding the limit of tolerance through significant increases or decreases in temperature. Along with the associated temperature change is the change in the amount of available moisture. Climatic stress is a very real thing as large areas exceed tolerance levels for the more sensitive species.

We will learn more about global cooling after the present global warming period ends; that is, if we are in another interglacial stage, as many scientists believe. With regard to global warming it is likely that emissions of methane gas (CH_4) in the sea floor, soils, and melting ice caps contribute to "greenhouse" gases in greater amounts than carbon dioxide. A large release of methane is often related to surface igneous activities, which are related to convection currents in the mantle, which in turn are related to plate tectonics. Such large emission of methane in the past may again take place in the future.

Extinction events, large and small, are continually being studied, particularly since the more recent glacial ice began retreating. These events tend to coincide with humankind exploring the land in areas where the ice was retreating, as well as other areas of the world. It is known that certain species of horses, camels, sloths, elephants, glyptodonts, peccary, antelope, and bison disappeared together over 8,000 years ago. The extinction of the mammoth occurred about 11,000 years ago. Certain birds also became extinct about the same time. And stratigraphic evidence, including volcanic ash, suggests that extinction of many species of tortoises occurred about 70,000 years ago, showing that climatic change and volcanic eruptions are both involved. Many archaeological sites show that extinction events closely followed the arrival of humankind. Very simply, civilization tends to shrink the range needed for other species: The Colorado squawfish, Carolina parakeet, California condor, Everglade kite, Eskimo curlew, and Labrador duck, among others, have become extinct in the past 200 years. These are not new observations about the diminishing wilderness and decimation of natural areas. Research continues as currently endangered species and the extent of their ranges are at the mercy of humankind.

A comparison of extinctions in the natural setting with those in the cultural domain is rendered difficult by the tendency to think in terms of human time rather than geologic time. Natural extinction events take thousands of years or even longer, while cultural extinctions occur in rapid succession with each technological innovation or societal upheaval. At the present time, as scientists continue to search for answers to the questions surrounding biological extinction, the paradigm of cultural extinctions may yield information useful in understanding and responding to these phenomena.

Extinction and Evolution

Charles Darwin (1809–1882) assumed that species have gone extinct in a steady and progressive way through the history of life; that is, over time. The diversity of life is reflected in the large number of present-day species, but a much larger number has existed over time, owing to the fact that extinction is the ultimate fate of all species; 99% of all species that have ever lived on Earth are estimated to have become extinct since life originated, about 3.5 billion years ago. A species' duration on Earth is very short on the geologic timescale; normally, a species becomes extinct within 10 million years after its origin. Thus, it is now widely accepted that species become extinct, but this fact was not known 200 years ago. It was previously thought that species were fixed in form, until Jean-Baptiste de Lamarck established that species change over time into new species. However, Lamarck assumed that lineages of species continue indefinitely without branching, so they did not go extinct.

Georges Cuvier (1769–1832) is accredited as the first to establish the extinction of species. He studied the fossils from large terrestrial mammals that had never been observed alive and realized that such fossils must not be overlooked. He considered that each species had had a different origin, and then it stayed stable in its form. Successive catastrophic events then drove these species extinct.

The principle of uniformitarianism, developed by the geologist Charles Lyell in his *Principles of Geology* (1830–1833), was essential for Darwin. It is simply that the basic physical processes involved in the present-day structure of the Earth are assumed to have been the same everywhere and at all times. In the pivotal work *On the Origin of Species* (1859), Darwin considered that the modern variety of species was the result over time of the process of descent with modification. Thus, the successive species are linked to each other by a branching genealogy, the tree of life. This tree-like evolution, where species disappear gradually rather than as a result of catastrophic events, allows for extinction. Darwin assumed that due to competition with other species, the causes of the extinction of species were mostly biological. However, there were a series of peak times when extinction rates appeared to be exceptionally high, now called mass extinctions, but Darwin attributed them to gaps in the fossil record rather than real catastrophic events. Today, the absolute dating of rocks by radioisotope methods has ruled that possibility out. Thus, Darwin held that extinction is coupled with the process of natural selection and is, therefore, a main element of organic evolution.

The Fossil Record: Evidence for Extinction

The fossil record is the main source of information on the history of life and it provides strong evidence for evolution and, therefore, for extinction. However, the fossil record is neither complete nor perfect. It contains merely a small part of all the species that have ever existed and not in a representative way. The proportion of species known from the fossil record is about 0.02%; in other words, about 250,000 fossil species. The fossil record is biased in favor of mineralized hard-skeleton invertebrate species, long life span species, and geographically and ecologically widespread distributed species. Foraminifera, single-celled eukaryote marine microorganisms, are one of the best groups to evidence organic evolution, as they show a widespread and almost continuous record with intermediate forms between species. But even with the best-recorded species, the exact time of extinction of a species is impossible to determine. The last appearance of a species in the fossil record usually happens before the time of extinction as a consequence of the lack of completeness in the fossil record. The misinterpretation of the fossil record may lead to what is called pseudo-extinctions. It means that a species (or higher taxon) apparently becomes extinct but it reappears in younger rocks. It may be due to taxonomic artifacts or to the incompleteness of the fossil record.

The divergence of species is usually based on physical expressed characteristics, that is, morphological and behavioral characteristics, but the latter are generally not observed in fossil species. Thus, two species that recently evolved from a common species may blur into each other, as would be expected in an evolutionary process. Furthermore, the extreme forms of an evolving lineage may seem sufficiently different that they are identified as different species, even more if due to the incompleteness of the fossil record when there are only few specimens recorded from the extremes so the evolving lineage cannot be detected. A second kind of pseudo-extinction due to taxonomic artifacts can occur in situations involving higher taxa above the species level. A paraphyletic group (an artificial group of taxa comprising a common ancestor but not all of its descendants) could become extinct although some descendants of that group continue to exist. For instance, the birds are descendants of one dinosaur group, which became extinct, but birds survived that extinction.

The so-called Lazarus effect is a kind of pseudo-extinction due to the incompleteness of the fossil record. A Lazarus species is one that disappears temporarily from the fossil record, but it can be inferred to have existed during that time by its reappearance in younger rock strata. However, its disappearance would be a pseudo-extinction if its later occurrence is overlooked. A mass extinction can seem artificially more abrupt, gradual, or stepped than it actually was because of the Signor-Lipps effect. Sampling gaps in the fossil record, through an interval of time before a mass extinction, may lead to the scattering of the last occurrence of taxa prior to their actual extinction.

The fossil record has been used to estimate the change of the diversity of life and therefore of the extinction rate through the history of life, compiling the time distributions of taxa in the fossil record. In the 19th century, the geologist John Philips, after plotting diversity against time, was able to recognize the great faunal transitions that mark the boundary between the Paleozoic, Mesozoic, and Cenozoic eras, that is, the major extinction events now called the end-Permian and Cretaceous-Tertiary (K-T) mass extinctions. But the most widely used compilation is that developed by Jack Sepkoski and published in a series of papers beginning in 1981. Three main conclusions are inferred from it: The average extinction rate seems to decrease from the Cambrian period (about 500 million years ago) to the present; there are five time periods of particularly high extinction rate, which have become known as the Big Five mass extinctions; and a periodic pattern of peaks in extinction rate occurs every 26.2 million years.

Extinction Over Time: Background Extinctions and Mass Extinctions

Extinctions have occurred throughout the history of life as a consequence of the branching structure of evolution. These extinctions are called *background extinctions*. The decline of the average extinction rate from the Cambrian period to the present is a controversial subject, because it may be an artifact caused by the way the extinction rate is measured. Diversity in the Cambrian is known to be lower than in the Mesozoic and Cenozoic eras. Consequently, for a given extinction rate, fewer taxa needed to go extinct. As a result of the branching structure of evolution, the numbers of species per genus and per family (higher taxa) have increased over time. Thus, fewer genera and families will go extinct through time for a given number of species going extinct. But the decrease in extinction rate may be real. Taxa may have become more resistant to extinction, perhaps suggesting progressive adaptive advances. Species may have initially occupied central niches (the position of a species within its environment and community, i.e., the habitats it occupies and the resources it consumes) that are subject to more intense competition than are marginal niches. Thus, a higher turnover of occupying species occurs. Over time, more marginal niches are occupied where the species may last longer and, consequently, have lower extinction rates.

The five major mass extinctions occurred at or near the ends of the Ordovician, Devonian, Permian, Triassic, and Cretaceous periods. The Permian mass extinction is the biggest in the history of life, with about 95% of the species going extinct. In the K-T mass extinction, where dinosaurs and ammonites (coiled-chambered shell cephalopods similar to the pearly nautilus) were driven finally extinct, at least half (and perhaps 75%) of species suffered extinction. Even though it is clear that the extinction rate was extremely high through mass extinctions, it is not clear whether mass extinctions are truly different from background extinctions. Thus, mass extinctions could just be the intensification of background extinctions, fully random or selective. In the last case, the most plausible idea, they would follow different rules than would background extinctions, which are responsible for the extinction of the vast majority of species.

It has been estimated that there was a periodic pattern of peaks in extinction rate every 26.2 million years during the Mesozoic and Cenozoic eras. However, not all predicted peaks coincide with known extinction events in the fossil record, and there was a lack of those peaks in the Paleozoic. Recently, another periodic pattern has been calculated every 27 million years, which clearly matches with the 26.2-million-year periodicity.

Extinction Selectivity

The combination of Darwin's theory of evolution by natural selection and Mendel's genetic theories constitute the modern synthesis, or neo-Darwinism. Species usually have excess fecundity so they generate many more offspring than can survive. This implies a competition within every species to survive, as the genes in the population of offspring are a random sample of the genes present in the parental population. The better-adapted forms to the environmental conditions, and thus the variants that improve survival or reproductive success, will increase in frequency and, eventually, a new species will be originated. Darwin considered that competition between species is the main cause for extinction, and thus all extinctions are selective. It is obvious that extinction does not affect all species in the same way, but more factors than only competition between species are implied. Species with large body size, ecological specialism traits, low reproductive rate, and slow growth are more likely to suffer extinction. Species with large body size are usually characterized by small populations and low reproductive rates; that is, they are rare. Species with broad geographic ranges are much less prone to extinction than species with smaller ranges, but not when extinction is so severe as during mass extinctions. In this case, survival depends on the geographic distribution of the entire group but not of the individual species. Tropical taxa usually suffer much more extinction than high-latitude taxa, but there is also no difference during mass extinctions. Species-rich taxa have lower extinction rates. Not all taxonomic groups show the same mean duration of their species, so those with shorter duration have higher extinction rates.

Taxonomic selectivity is not common, but occasionally it is prominent. Such is the case of the extinction of the trilobites (arthropods gone extinct at the Permian mass extinction), dinosaurs, and ammonites at the Mesozoic mass extinction. This evidence—that taxonomic selectivity may operate at higher levels than the species level—makes it possible that diverse higher taxa have become extinct. Therefore, mass extinctions can drive taxa extinct not because they are poorly adapted to normal environmental conditions, but because they happen to lack adaptations to the new conditions or characteristics, such as lacking extensive geographic ranges that favor survival during the extinction. These contrasts in selectivity between mass extinctions and background extinctions evidence the evolutionary importance of mass extinctions. Even though they account for less than 5% of the total number of species that have become extinct through the history of life, they can drive to extinction well-adapted and successful taxa. This makes sense in terms of evolution, as natural selection cannot ensure that its taxa will survive sudden abrupt environmental shifts. The species selection pattern can even shed light onto the nature of the mass extinction event.

Understanding the causes of the mass extinctions has become an important and controversial issue since the proposal of a giant meteorite impact as the main or triggering cause for the K-T boundary mass extinction. Other common abiotic causes of major extinctions are climate change, volcanism, sea-level changes, anoxia (low-oxygen conditions), and shifting continental position. However, the evolutionary consequences of mass extinctions are probably more important than the events themselves.

Evolutionary Consequences of Mass Extinctions

The evolutionary process following mass extinctions is a key to the postextinction role of the diversity of life as new evolutionary opportunities are created by the demise of dominant groups. After the dinosaurs became extinct at the K-T mass extinction, the mammals radiated rapidly and occupied the ecological space vacated by dinosaurs. Mass extinctions triggered the diversification of survivors, not only in terms of numbers of species but also in terms of morphological or ecological variety. However, the fossil record shows that not all survivors radiate after mass extinctions, and therefore survival alone does not guarantee evolutionary success. The diversity of survivor groups can follow different ways over time after a mass extinction. Some groups accelerate diversification following the extinction event, as is the case with mammals after the K-T mass extinction. Others groups suffer a delay just after the extinction event. Some of them rapidly recover and continued their diversification, but others never really recover from the mass extinction. The latter usually disappear several million years after the mass extinction, although some of them manage to survive until the present day, and they are often called living fossils (e.g., the pearly nautilus). Immediately after the mass extinction event, severe environmental conditions persist, and they can even prompt more extinctions and delays in species recovery. Mass extinctions, which are especially severe among rare and restricted distributed groups, tend to homogenize the postextinction fauna. Low-diversity assemblages dominated by generalist species characterize these intervals. Generalist species are often small in size, and under normal conditions they are rare, with very few populations. Even though mass extinctions have provided major evolutionary opportunities, they did not trigger such a big diversification of life as the one at the beginning of the Paleozoic era, the Cambrian explosion, when most of the major groups of animals appeared for the first time, as evidenced in the fossil record.

The recovery process after a mass extinction can show considerable variety all over the world. Furthermore, recovery processes are different for each mass extinction as different taxa and different ecological, climatic, and oceanographic settings are involved. Thus, the speed of recovery may differ between mass extinctions, but the fossil record shows that it always takes a long time to recover, as much as 10 million years.

Today, the extraordinary proliferation of just one species, our own, is triggering what is considered to be the sixth mass extinction. It may be viewed as not natural, but the fossil record provides strong evidence for mass extinctions throughout the history of life. Moreover, the fossil record provides evidence of recovery after all of them. Apparently, we should not be worried about a sixth mass extinction of all life on Earth due to the misguided actions of our own species. However, the fossil record also shows us that the evolutionary recovery of biodiversity is extremely slow compared to a human lifetime and a long time compared to the total life span of our species so far. Impoverishment is the legacy of extinction on human timescales, but extinction also creates new evolutionary opportunities. Even so, survivors of mass extinction are not always the best adapted, just the luckiest. Of course, not all survivors are going to be successful in terms of ongoing evolution.

Extinctions, Mass

Unlike an extinction, which affects a single species, a mass extinction is the large-scale elimination of multiple species caused by catastrophic global events. There have been five mass extinctions in geological time. It is believed that a sixth mass extinction is currently in progress, the first since the advent of humankind.

Ordovician Mass Extinction

The first mass extinction took place at the end of the Ordovician time period 438 million years ago (mya). Life forms in the Ordovician period were restricted to the seas, and the Ordovician mass extinction is one of the most devastating extinctions in geological history, with more than one quarter of Earth's marine species being eliminated. Numerous species of the trilobites and brachiopods were eliminated, while graptolites and conodonts were also seriously affected. Over 100 marine invertebrate families were destroyed in the mass extinction. Scientists attribute the cause of the mass extinction at the end of the Ordovician to glaciations and the consequent drop in sea levels. As a result of the drop in sea levels, there becomes a shortage of inhabitable space on the continental shelves. Along with this shortage, the sea temperature dropped as a result of glaciations, also affecting life forms.

Devonian Mass Extinction

During the late Devonian period, a second mass extinction swept the earth around 360 mya. The reefs faced near elimination, as did several other marine animals. Creatures affected included brachiopods, trilobites, and conodonts, as well as the placoderm armored fish. Land records for this time are less clear, and it is possible there was a major extinction among land flora.

Permian Mass Extinction

The Permian mass extinction is the largest mass extinction in geological history. This extinction ended the Permian period, 250 mya, and marked the transition between the Paleozoic and Mesozoic eras. The effect of the mass extinction reached across both land and sea, wiping out over 90% of all species on Earth. Over one half of the marine species perished, including the rugose and tabulate corals, fusulinids, and several echinoderms. Brachiopods also suffered, ending their dominance in population. There was also a regionally vital extinction among plant life. The last of the trilobites were eliminated during the Permian mass extinction. Over one half of the vertebrate families were lost. The exact cause of the mass extinction is debated, with speculative causes including major volcanic eruptions, glaciations, and changes in sea level. Some scientists attribute the mass extinction to the collision of the Gondwana and Laurasia land masses to create the land form Pangea. Another theory includes a massive comet or asteroid impacting Earth, which would have also contributed to the mass extinction.

Triassic Mass Extinction

The Triassic mass extinction happened 50 million years after the previous mass extinction, about 200 mya. By this time, a number of land and marine life forms had repopulated the earth, and reptiles had evolved into crocodile-like animals and a few mammal-like reptiles. Most of these animals were destroyed in the mass extinction, including conodonts, and others, such as the calcareous sponges and shelled ammonites, were nearly wiped out. The cause of this mass extinction is believed to be the result of a combination of catastrophes happening over the span of 100,000 years or less. These events include an estimated 4-mile-wide meteor impacting Earth near Quebec, creating a 70-mile-wide crater; eruptions of lava flow underneath the Amazon river valley; and a dramatic change in climate. Together these events were sufficient enough to create a mass extinction, allowing the dinosaurs to emerge.

Cretaceous Mass Extinction

The best-known mass extinction took place 65 mya, ending the reign of dinosaurs and the Cretaceous period. This mass extinction marks the elimination of the calcite-shelled phytoplankton, coccolithophorids. Also eliminated in this extinction were the ammonites, belemnite cephalopods, and the primitive bivalves. Among the land-roaming animals, dinosaurs were wiped out in the Cretaceous mass extinction, allowing mammals to dominate Earth in the Cenozoic era. It is believed that a combination of catastrophic events is to be attributed to the cause of the Cretaceous mass extinction. The most drastic event was the impact of a 6-mile-wide asteroid colliding with Earth near the Yucatan Peninsula. This event created widespread forest fires, giant tidal waves, and massive amounts of poisonous gases in the atmosphere. There were months of darkness due to the large quantities of Earth and asteroid debris in the atmosphere, blocking out the sunlight. Numerous species of plants died and herbivorous animals starved. Over half of the species on Earth perished.

Causes of Mass Extinctions

The causes of the various mass extinctions are debated, including theories of volcanic eruptions, meteor impacts, sea-level changes, and climate changes. Mass extinctions do not happen overnight but rather over a period of thousands of years. Major volcanic eruptions create deadly gases in the atmosphere, resulting in a number of side effects. There is a regional warming due to the sulfur dioxide released into the atmosphere, as well as global warming from the carbon dioxide. These global temperature changes can affect a number of flora and fauna if, like coral, they are delicate in response to temperature change. Throughout prehistory, a dominant species of a period was not overthrown by another species but rather by a mass extinction. This allowed other species to evolve and become the next dominant group. Mammals existed during dinosaur domination; however, it was not until a mass extinction eliminating all nonavian dinosaurs that mammals evolved further and became the dominant life form. Mass extinctions were also fairly selective in which species were affected. An example is during periods of global warming or glaciations, species that survived within limited latitudinal distances were more strongly affected because of their inability to adapt to thermal changes. Other species living in a wider latitudinal range were more likely to tolerate the thermal change.

Future Mass Extinctions

Although a number of species have become extinct, there has not been a mass extinction since the dawn of humankind. Of the 1.7 million known species, only 5% of them have been catalogued, and there is an estimated 5 million to 50 million unknown species. It is estimated that 1 out of every 1 million species became extinct per year prior to human existence. It is estimated that today 1 out of every 1,000 species is becoming extinct. This rise in the rate of extinction is attributed in part to anthropogenic activities. This rate of extinction is rivaled only by the three most catastrophic mass extinctions, leading many scientists to believe we are heading toward, or are already in, a sixth mass extinction.

F

Farber, Marvin (1901–1980)

In the history of recent philosophy, Marvin Farber represents a bold thinker who dared to change his intellectual interests in light of continuing advances in the special sciences. Although he was at first drawn to the rigorous study of phenomenology with its focus on pure consciousness, Farber later became very critical of its subjective orientation and limiting methodology; he stressed that there is a crucial distinction between a claim about existence (ontology) and a method of inquiry (epistemology). Farber realized that phenomenology alone is unable to adequately answer important questions concerning ethics, epistemology, and metaphysics. It was Farber's serious acceptance of the fact of evolutionary time that resulted in his academic shift from idealism to materialism. The awesome cosmic perspective in astronomy and the disquieting implications of human evolution in anthropology convinced him that the sweeping temporal framework in modern science offered the only true interpretation of the fleeting place our species occupies in a dynamic universe.

Although Farber had studied phenomenology under Edmund Husserl (1859–1938), he found greater value in the diverse ideas of Giordano Bruno, Ludwig Feuerbach, and Friedrich Nietzsche. Bruno held that this universe is eternal, Feuerbach claimed that religious beliefs are the product of human psychology, and Nietzsche taught that "God is dead!" and therefore new values are needed to replace traditional superstitions. Farber incorporated these penetrating insights into his own critical investigations of the human situation. Furthermore, Farber's concern for human problems found inspiration in the social analyses of Karl Marx, Friedrich Engels, and Vladimir Lenin. Farber accepted the materialist stance and historical framework of these three social theorists and, with a keen sense of human compassion and critical optimism, he anticipated the emergence of increased enlightenment as our species embraces the ongoing findings of science and the indisputable power of reason.

Charles Darwin's theory of evolution had had an enormous influence on natural philosophy. It challenged the previously accepted age of this planet, fixity of species, and recent appearance of humans on the earth. The remarkable discoveries in geology, paleontology, anthropology, and biology (particularly genetics) throughout the 20th century yielded overwhelming empirical evidence to support the scientific fact of organic evolution. Farber stressed the independent existence of the evolving world from human consciousness. His own ideas went far beyond the myopic views of existentialists and even the pragmatic naturalism of John Dewey (1859–1952), whose philosophy retained a concept of God. Moreover, Farber advocated a pervasive naturalism that not only rejected all forms of spiritualism and supernaturalism, but also removed humankind from any special position in the flux of cosmic reality. Among the recent major philosophers, he stood almost alone as an unabashed atheist and uncompromising materialist.

Darwinian evolution contributed the fatal blow to any earth-bound and human-centered worldview. Marvin Farber acknowledged the quintessential value of having a sound comprehension of time in order to properly and accurately explain reality, whether it be cosmic history or human existence within it. His own naturalist attitude and refreshing vision, with its steadfast commitment to pervasive evolution, offered a sobering interpretation of our species grounded in an open inquiry that respected both scientific evidence and philosophical reflection.

Fatalism

Fatalism is the belief that the future is fixed and that there is nothing we can do about it. It implies that our wills are causally inefficacious.

The Fates of Mythology

The belief in fatalism, like many others, has its roots in the quasi-religious mythologies of ancient peoples, many of which personified the notion of fate. Thus Greek mythology supposed that three Fates, daughters of the goddess of Necessity, had control of our lives from beginning to end and that it was therefore impossible for us to do anything contrary to what they had prescribed for us. We may think we are in control of our own destinies, but we are mistaken. Both Homer's *Odyssey* and Aeschylus's *Prometheus Unbound* depict mortals as puppets of the gods.

Fate and Predestination in Monotheistic Religions

Belief in the Fates has a correlate in each of the three main monotheistic religions: Judaism, Christianity, and Islam. In all three the concept of fate or destiny mutates into the theological doctrine of predestination—the doctrine that there is a Book of Life in which are written the names of those whom God has selected for salvation or damnation. As St. Paul took pains to point out, a person's ultimate future is already determined by the grace of God, not by anything we can do of ourselves.

This form of fatalism is often linked to the doctrine of God's foreknowledge. The God of theism is supposed to be omniscient (all-knowing) as well as omnipotent (all-powerful) and omnibenevolent (wholly good). By virtue of his omniscience, it has been argued, God knows our futures right down to the finest detail. Hence, it is concluded, we can't do anything other than he already knows we are going to do. The details of our daily lives, as well as our ultimate destiny, are already set (if not in stone, then in God's mind). Much theological debate has raged over which doctrine takes logical precedence: foreknowledge or predestination? Is God's foreknowledge of our futures a consequence of his having predetermined them? Or is it the other way around?

Such sayings as "Thy will be done"—whether the word "thy" is taken to refer to the Jewish Yahweh, the Christian God, or the Muslim Allah—incorporate the fatalistic suggestion that nothing can be done that is contrary to God's will. There's no use in struggling against it; one must simply submit.

Commonplace Sources of Fatalistic Belief

Belief in fatalism can have much humbler sources, as in such commonplace observations as "It wasn't in my stars," "It wasn't meant to be," "I guess his number was up," or "What will be will be." Persons mouthing such sayings may have some astrological, religious, or metaphysical doctrine in mind. But they need not. They may utter them without even pausing to ponder what, if anything, they mean. Thus can the inanities of ordinary language lend support to vague and unexamined philosophical doctrine.

Philosophical Sources of the Doctrine of Fatalism

Serious philosophers, too, can be led to flirt with fatalism by reflecting on matters of language and logic. Aristotle was a case in point. In *On Interpretation,* Aristotle puzzled over the application of logical principles to statements about the future. His example was, "There will be a sea-fight tomorrow." Clearly, he reasoned, this statement must—by his own Law of the Excluded Middle—be either true or false. Suppose it to be true. Then, it seems, there is nothing and no one that can bring it about that the sea battle will *not* occur. Otherwise the statement would not have been true. Suppose the statement to be false. Then, it seems, we can conclude that there is nothing and no one who can bring it about that the battle *will* occur. Otherwise the statement would not have been false. It seems, then, that logic itself dictates that the future, whatever it holds in prospect for us, is fixed and occurs of necessity. No one, on this analysis, can do anything to make the future be other than it is going to be.

Some thinkers have concluded that logic does indeed provide a sound basis for believing fatalism true. Others have thought to escape from fatalism by finding a path between the alternatives of statements being either true or false. Statements about the future, some have said, are neither determinately true nor determinately false. So-called three-valued logics have been devised accordingly. Still others have claimed that there is a fallacy involved. They have argued that from the truth of a statement about the future—that such and such an event will occur—all that follows is that it *will* indeed occur, not that it "must" occur. Likewise for the case where such a statement is false: All that follows is that the event *will not* occur, not that it "cannot" occur. There's no hint of fatalism in either case.

Determinism Distinguished From Fatalism

It is sometimes supposed that the doctrine of determinism—in the form of a belief in the causal interconnectedness of all events, from past to present and thence to the future—also has fatalistic implications. But surely this must be wrong. A determinist can well believe that just as our present actions are the effects of past events, so our present actions have their own effects and so can play a role in determining future events. That is to say, a causal determinist can consistently say that our wills are causally efficacious, at least some of the time. Since fatalism denies that our choices can have any effect on what the future is to be, a fatalist cannot consistently say this. Hence determinism does not imply fatalism.

Father Time

The intangible passage of time, challenged only in photographs, is an unstoppable entity with no clearly defined scientific beginning or end. As with grains of sand passing through an hourglass, there is nothing one can do to stop or freeze time itself in order to hold on to one specific moment. This leaves us with only memories. This concept of time, being such a powerful and unforgiving force, is commonly represented by the old and wise figure known as Father Time, which can be traced back to the early Romans and Greeks.

Before the ancient Greeks recognized the brothers Zeus, Poseidon, and Hades as rulers over the world, they worshiped their father Chronus (*Khronos*) (Latin root *Chronus* meaning time), the god of time. The Roman equivalent *Kronos* not only doubled as the Titan god, but also was seen as the god of agriculture (also giving him the name Saturn), often causing him to be portrayed with a scythe. There was also an annual midwinter weeklong harvest celebration called Saturnalia, held to honor, thank, and celebrate Saturn.

Father Time is traditionally depicted as an old, bearded figure, and as previously mentioned, always with a scythe at his side. To stress just how powerful he was, however, some ancient Romans depicted Kronos as the personification of Aion ("eternity"), a masculine and youthful god. Some murals show him against the sky holding a wheel inscribed with the signs of the zodiac. But for the Romans, the traditional portrayal with the scythe represents the sowing and tilling of the land each year, which brought about bountiful harvests. Like the Greeks, the Romans recognized Kronos's great importance as the god of time. In mythology, the ultimate flaw in any humans attempting to perform heroic feats was their mortality, giving the scythe a symbolic representation of how life is not only short, but also can be quickly and decisively ended at any point. This had been seen, and still is seen, as perhaps an inspiration to take the fulfillment of life's purposes with urgency.

The image of Father Time is culled from several sources, including the Holly King (a mythical figure), the Celtic god of the dying year, and Chronus, the Greek god of time.

Source: Archive Holdings Inc./Getty Images.

A similar equivalent character in contemporary society would be the Grim Reaper, as he is also always seen carrying a scythe, and like Kronos is much feared. But awareness of the figure Father Time is not completely removed from current society, and still carries the same messages; he is even mentioned and sung about in popular music. Father Time possibly has another connection to current popular society through his striking resemblance to the figure of Santa Claus. In the year 354 CE, Pope Liberius, originally Peter Valvomeres, declared that the observance of the birth of Christ would be on December 25. It is thought that perhaps this was done in hopes of drawing attention away from the pagan Saturnalia (in which there was also gift giving). Some movies and books portray Father Time as even having a connection with Christmas by stopping or slowing down time, allowing for Santa Claus to have time to travel all over the world in one night. Father Time is also sometimes recognized in popular culture soon after, in the recognition of the New Year. It is seen that with each passing year, at the striking of midnight, Father Time takes the old year and "passes on" the duties of time to the Baby New Year, who will in turn be transformed into Father Time during the months ahead.

Fertility Cycle

The creation of new life has always mystified and intrigued human beings. One source of this fascination

Source: Getty Images.

is the cycle of fertility, which governs the existence of all living things. Indeed, the short period many species have to reproduce makes each fertile season extremely important. For people, finding ways to encourage fertility has been a goal for centuries. We now know that many factors affect human fertility, including age, nutrition, physical health, hormones, and genetics. Even with the advancement of medical technology in recent decades it is still difficult for some couples to conceive. It is easy to see why ancient societies would have put so much hope in magic and religion. Worship of gods and goddesses, festivals, and sacrifices have all been practiced in the hope of promoting life.

As vital to the survival of human civilization as the fertility of men and women is the fertility of crops. The time constraints of the reproductive cycle also impact agriculture. Because of the limits of seed growth, famines have killed millions of people throughout the centuries. Climate factors and disease also can destroy an entire season of crops. For example, the potato famine of Ireland in the 1840s not only killed many people but also caused mass emigration from that country. Ancient cultures learned quickly that the survival of the harvest was vital to the survival of the people.

Most cultures have had deities associated exclusively with the celebration of spring's growth and the fall's harvest. Before the advent of modern biological science, people could only guess at what helped to encourage life. The earliest farmers believed that their crops were inhabited by spirits that caused them to thrive or die. It was believed that the spirits were released when the plants were harvested. The harvesters began to perform rituals to thank the spirits for the crops that survived. This tradition continued and was practiced in most of the major civilizations throughout history.

In Egypt, Osiris was worshipped as the god of agriculture and was often depicted with a green face representing fertility. He was also the god of the dead, showing the Egyptian belief in the connectivity of life and the afterlife. The story of his death and resurrection was used as an analogy for the cycle of life. Every year the Nile flooded the plains and made the soil rich and fertile. During this time the Egyptian people had a festival celebrating the rebirth of Osiris and the opportunity for a new harvest to grow.

The Greek goddess Demeter was the patron of agriculture and fertility. She was believed to have taught humans how to tend the soil and raise crops. Thesmophoria was the festival held in her honor. It took place right before the harvest in hopes of achieving a bountiful return. These celebrations of life often included music, sports, and feasting. The goddess was known as Ceres in Roman times; her name translates to mean "grain mother." Some believe that the term *Mother Earth* was created to describe this goddess.

Native North Americans celebrate the Green Corn Festival when the harvest is ready to be gathered. During the first few days people cleanse themselves and their homes to prepare to welcome the new crop. The festival lasts for many days and includes dancing, sports, and feasting. It is thought that the American tradition of Thanksgiving comes from colonists attending this celebration.

Every species' primary goal is to thrive and reproduce. To accomplish this, human beings have created many rites and rituals. Pagan groups revered rabbits as symbols of fertility. Rabbits can produce several very large litters every year, and females are able to be impregnated with a second litter while still carrying a first. Early peoples were amazed and envious of rabbits' extraordinary ability to procreate. The tradition of the Easter Bunny originated among early Christians in the incorporation of pagan spring traditions into the celebration of Easter, which occurred at the same time of the year.

Typical ancient African fertility goddess, carved on wood, West Africa. The worship of gods and goddesses, festivals, and sacrifices has all been practiced in the hope of promoting life. The fertility of crops is as vital to the survival of human civilization as the fertility of men and women.

Source: Diane White Rosier/iStockphoto.

The Greek goddess Aphrodite, known among the Romans as Venus, was worshipped as the personification of love, beauty, and sexuality. Her festival was the Aphrodisiac and was celebrated throughout Greece in the spring. During this time people ate and drank certain items that they believed would increase fertility. The term *aphrodisiac* is still used today to describe foods with these qualities. Some people believe Aphrodite's connection with water is the reason that some seafood is considered as such. During the festival, orgies were encouraged and sexual intercourse with a priestess of the goddess was considered the highest form of worship. Hera was the goddess of marriage and motherhood and was also prayed to for help with fertility and reproduction. Her Roman counterpart was Juno.

In ancient Egypt, Min was the god of fertility and sexuality. He was worshipped as a god of the harvest but was primarily seen as bestowing sexual powers. Min is often depicted with an erect phallus. In Egypt, lettuce was believed to be an aphrodisiac and was eaten in the spring to promote reproduction. Bast, the goddess of fertility and childbirth, was represented as a woman with the head of a cat. In Egyptian society cats were believed to be divine and to have the power to give life. There were many festivals for Bast throughout the year. As with Aphrodite, some of the Egyptian fertility festivals included orgies.

In recent decades the human population has increased dramatically. Health care and food preservation technology have decreased infant mortality and increased life expectancy. Overpopulation has become more of a dilemma for the human species than the fear of extinction. Consequently, some people now use medicine and technology to shorten or even stop both male and female fertility cycles.

FEUERBACH, LUDWIG (1804–1872)

Ludwig Feuerbach, German philosopher, was noted for his materialistic interpretation of God/ Christianity and humankind within a temporal framework. Although his philosophical and anthropological perspective was established before the theory of evolution (1859) by Charles Darwin (1809–1882), Feuerbach understood that the emergence of consciousness allowed humankind to integrate intelligence and emotion with the understanding of human mortality. Consequently, the concept of God, theology, and religiosity manifested itself in various ways in order to bring both ontological and teleological fulfillment to a personal finite existence. This materialistic and heretical explanation encompasses a range of metaphysical implications from religion to scientific and philosophical enlightenment. Feuerbach recognized that God, prayer, love, and the desire for immortality are deeply rooted in the psychology of the human species. Essentially, God and his attributes are humanity's projection of itself that is juxtaposed within the finitude of human existence and understanding. Scientific and philosophical knowledge has aided (and for Feuerbach must continue in the future to aid) humankind's understanding of itself within an evolving universe. Feuerbach's major works include *Thoughts on Death and Immortality* (1830), *The Essence of Christianity* (1841), and *Principles and Philosophy of the Future* (1843).

Experience, Identity, and the Infinite

Feuerbach presented a unique interpretation of time conditioned by human experience. The combination of emerging consciousness tempered with external experiences allows for a shift in the personal beliefs expressed within the historical context of individual and social integration. In these terms, personal and social identity become transformation events that alter perception, morality, and anthropomorphic qualities of deities. The changing qualities of deities, as with the concept of immortality, denote the distinction of these temporal shifts in thought. From the lost perspective on mortality of the ancient Greeks and Romans to the independent governing factors in individual immortality, the concept of God(s) becomes both a temporal and superficial essence. Ultimately, this essence is humanity's finite projection of the infinite that is, God. During this projection, humankind surrenders its inner being to a self-created nonexistent entity.

In Feuerbachian terms, the concept of time, when finite and infinite are juxtaposed, creates a sense of temporal eternity by which finitude is expressed in personal mortality. This awareness of death, a complete termination and dissolution of life and spirit, is a precondition of human life limited by human reason. The human spirit, which is equated with consciousness and reason, is limited within these parameters of a material existence. Although individual existence and individuality are temporal, human thought is considered by some to be beyond time; albeit solely dependent on the temporally finite material body. This in itself raises a perceived paradox. For Feuerbach, temporal experience (finite) and thought (finite yet infinite within finite consciousness) foster a sense of infinity that is in itself a finite spatiotemporal existence. Personal immortality becomes an illusion that is less illustrious than an infinite and personal God.

As Feuerbach pointed out, God and religion mirror human nature. The concept of God, a created and projected illusion subjected to shifts in definitions within time, is unique in human thought. God has become the archetype for the simultaneous existence of both the material/nonmaterial and finite/infinite. Consequently, the expressions of anthropomorphic qualities of God—life, emotion, infinite consciousness—and nature are steeped in mystical interpretations of the human quest for immortality. The greatest manifestation of this quest is seen in the basic and contradictory principles of Christianity. Concepts of the Trinity, Christology, and the Resurrection combine the supreme ideal—nonmaterial, infinite, loving, and omnipotent—with the antithetical states of human life, the limitations and frailties of human existence. When compared in this manner, sin becomes a self-imposed conceptual prison from which humankind seeks to free itself, via prayer, and reaffirm itself in value and unifying identity. However, rational and critical thought expose several contradictions within religious thought as presented by Feuerbach; among them God (essence), doctrine, and revelation being the greatest of all contradictions.

Feuerbach held that humans are unique in the animal world. Essentially, humans are held to be universal beings that reflect the totality of their being: unlimited and free. Artistic creativity, philosophical contemplation, and science are signs of this totality or unity. Differing from Aristotelian, Platonic, medieval, or modern philosophy/theology, the materialistic completeness or unity is regarded as the essence of being human. It signifies a metaphysical shift to a form of materialism that encompasses all known reality of human existence. Furthermore, Feuerbach understood the relevancy of scientific advancements—that is, creativity precedes science—and the role of philosophy in ultimately reclaiming humanity's loss and bringing about a completeness of being. This process begins with the task of what Feuerbach stated as the transforming and dissolving of theology into anthropology. Though Protestantism was considered as the beginning, Feuerbach would find today's humanism and advancements in science, especially in anthropology, biology, and psychology, as a progressive step in fulfilling this philosophical transformation. It is uncertain what direction this futuristic philosophy would take. However, the abstract notion and metaphysical implications of infinity and finitude will be redefined in the light of creative scientific advancements in biology (including physiology), physics, and technology; all of which will bring about a refined ontology and self-directed teleology. This signifies a continuous and dynamic process, as seen in Feuerbach's philosophical framework.

Feuerbach's Impact on Philosophy

The consequence of Feuerbach's thought on philosophy has been profound. Although materialism and naturalism were not new philosophical perspectives, Feuerbach did provide a new direction in the explanation of the human condition. His understanding of theology, particularly Aquinas and Hegel, combined with the spirit of the Enlightenment sought to free humankind from its perceived illusions of God and religion. This philosophical, albeit psychological, explanation forced a progressive reevaluation of the terms by which life and time are understood. Unlike Friedrich Nietzsche (1844–1900) in his proclaiming the death of God and the eternal recurrence, Feuerbach's humanization of God and religion becomes less nihilistic but retains discomforting thoughts about human finitude and mortality. Within the concept of time, human existence, both individual and as a species, is tenuous. In Feuerbach's view of reclaiming all parts of humanity, a complete unity of being can be attained and human fulfillment achieved. This is the essence in the finitude of humans in relation to the external world.

Fichte, Johann Gottlieb (1762–1814)

Johann Gottlieb Fichte was born on May 19, 1762, near Bischoffswerda in Saxony. He was a prolific writer, but space permits only a few of his works to be mentioned here. His ideas on time resolved largely into his notion of history.

Fichte studied at the prestigious University of Jena and then became a private tutor in Switzerland. Inspired by Kant's critical philosophy, Fichte published *Versuch einer Kritik aller Offenbarung* (*Attempt at a Critique of All Revealed Religion*) anonymously in 1792. Kant praised the work and made public that Fichte was its author. This made Fichte a formidable intellectual in the public mind, but the work's critical nature aroused suspicions of atheism. Fichte was greatly gifted in rhetoric, and he gained a wide reading audience in a series of publications. In 1793 he was offered a professorship at Jena at the suggestion of Johann Wolfgang von Goethe. He published a work in the same year designed to sway the German public to support the French Revolution. In the next year, *Grundlage der gesammten Wissenschaftslehre* (*Groundwork for* *the Entirety of Science*) appeared, which contained Fichte's attempt to turn Kantian metaphysics into a science deriving from a single principle. In their most exact form, Fichte's metaphysical ideas on time are found in the *Groundwork*. There followed *Das System der Sittenlehre* (*Science of Right*) in 1798, which showed the public that Fichte's scientific idealism would be a highly ethical, even moralistic and preachy, sort.

When he published *Über den Grund unseres Glaubens an eine göttliche Weltregierung* (*On the Grounds of Our Belief in a Divine World-Order*) in 1799, Ficthe ironically came into conflict with the University at Jena over charges of atheism. He had suggested in this work that the divine world-order requires human agency to become actualized. But the orthodox view was, of course, that the Divine Will of God cannot be thwarted by human free will, and the university officials supported orthodoxy. So Fichte moved on to Berlin.

There he published *Die Bestimmung des Menschen* (*The Vocation of Man*) in 1800. This highly popular work made his obscure scientific system accessible to the general reading public. Though *The Vocation of Man* was short on detail, the reader could discern the outlines of Fichte's notion of time. Strictly speaking, *secular time does not exist,* according to Fichte. Time as a metaphysical form and time as all of human history, have an essentially *sacred* nature. Time, independent of a Divine Will, simply cannot exist, because the internal form of intuition is a tool in the hands of the Creator; further, all historical events are manifestations of his will, for Fichte, but are achievable only if human beings freely choose sacred time. Man's free will creates the Divine world-order, in short, a notion that alarmed some readers. This insistence that *all time is sacred* sought to rescue history from empirical (English) science and from Spinozism. In this sense, Fichte's notion of history is more akin to Herder and Jacobi than Kant.

Fichte was awarded a professorship at Erlangen in 1805. In a series of lectures, Fichte argued against Schelling, among many others. While at Erlangen he also published *Reden an die Deutschen* (*Addresses to the German Nation,* 1800) to rally Germans after their defeat by Napoleon. In 1809 he became a professor at the University of Berlin. Fichte died on January 27, 1814.

Reputation as a Philosopher

Among his contemporaries, Fichte's reputation as a philosopher fluctuated wildly. In his *Lectures on the History of Philosophy,* Hegel judged that Fichte had completed and improved Kant's system. Fichte's one-time student Arthur Schopenhauer, on the contrary, considered Fichte to have been a charlatan capable of advanced rhetoric, but no more. The court of history, at least to date, has largely relegated Fichte to having been a minor idealist philosopher between Immanuel Kant and Georg Wilhelm Friedrich Hegel. And Fichte's status as an important figure in early German nationalism and the proto-Fascist economic system, and as an anti-Semite, has not aided his reputation. For recent scholars more interested in a philosophy of nature, Fichte has been overshadowed by his younger-yet-close friend Friedrich Wilhelm Joseph von Schelling.

Fichte on the Ego

Once Kant had introduced his "critical philosophy," thinkers began to question whether he had deduced the transcendental ideal structures of the "noumenal world," including time and space, correctly. Each post-Kantian philosopher reinterpreted and/or restructured the newly discovered noumenal world according to his own vision. For his part, Fichte reduced Kant's noumenal structures to the "transcendental ego," which he considered co-terminal with man and God, or more accurately, absolute ego is the identity of transcendental and empirical ego.

He began with the principle of identity, A = A, which would serve as a foundation for German idealism. Fichte played on the ambiguity between empirical ego and transcendental ego, and took the principle of ego (I = I), or the autonomous free self, to be the supreme principle upon which the rest of his idealist system would be based.

And yet the ego supported only his "science of knowledge." There is also faith in God, the transcendental ego, which in turn supports the empirical ego. God's existence is of the greatest certainty, and is the truth transmitting certainty to all other truths, argued Fichte in *The Vocation of Man.*

God has a Divine Plan, which has been produced through the transcendental ego and empirical ego.

Why this plan, and not another, was chosen by God, Fichte admitted was the great mystery of the world. Still, in Fichte's deeply religious worldview, the vocation of man is not only to know, but to have faith, too.

Fichte's Ideas on Time

As for time, Fichte accounted for it, like everything else, as a product of the self-positing I = I. The ego most certainly exists, he argued, in agreement with Descartes. In its second logical moment, however, the ego posits an object (a "non-ego") outside itself. "Inasmuch as I posit another in opposition to the ego, I posit myself as not posited." In other words, the ego structures objects that it then places outside itself, as if they were independent of the ego. The ego takes objects not as its own production but as part of an outside world. Yet all determinations of the object are ideal.

Time and space are examples of the division of ego and non-ego, which limit each other. Time limits space, and space limits time. The self views its own mental faculties operating in time but considers objects to exist outside, in space. In terms of identity,

I = Time, whereas Not-I (Object) = Space

In the third moment of his logical system, both ego and non-ego are partially negated to arrive back at the identity of ego with itself. For Fichte, this third moment is always moral and religious in nature. And so in this sort of spiritual insight, the limitations of one's own empirical ego are recognized, but also the limitations of the outer world constructed by the ego in the form of non-ego. The empirical ego, in its *partial negation,* comes to understand its own higher identity with the transcendental ego.

This means that the entirety of time has been produced from sensations and transcendental structures for a distinctly religious, moral purpose. (This notion that time is essentially a means toward a hidden divine end can be traced all the way back to Anaximander at the dawn of Western thought, but most directly from Herder.) Human beings are challenged by life not only to learn and know, but also to act—that is, to act morally. Only in this way does humankind bridge the subjective element of its existence with the objective world, which in the moral third moment is an ethical ideal outside one's self. Thus his idealism ended in a rather uncompromising piety.

Evaluation

From a Hegelian perspective, Fichte set out with the identity of subject and object, but then privileged the subjective as the absolute, after all. There was no final place for nature in his account; the ego produces all of time and space. For Hegel, Fichte came back again and again to only the empirical ego, and so was a subjective idealist. Even though Hegel considered Fichte's logic much clearer than Kant's method, history has judged otherwise. Much of Fichte's obscure argumentation met with criticism among his contemporaries.

To his great credit, though, Fichte's major contribution, again according to Hegel, was in his insistence that philosophy must become a scientific system following from a single principle.

FILM AND PHOTOGRAPHY

Film is traditionally understood to be the material medium that unites photography and cinematography. Photography and cinema are, together, distinguished from other media by sharing this material basis. In fact, the earliest photographers did not use film, but, rather, glass or polished metal plates, and a modern photographer or cinematographer is increasingly likely to use electronic means of recording rather than film. Nevertheless, film is the best starting point for appreciating both what these media have in common and what differentiates them. Specifically, they differ in respect of their representation of time: photography produces a still image of a moment frozen in time, whereas cinema employs film to produce a moving image that shows time passing. The representation of time, the technological control of time, and the viewer's experience of time are all features that have crucial importance for the application and the value of film media.

The term *photography* was established by John Herschel (1792–1871), in an 1839 presentation to the Royal Society in England. The Greek words *photos* (light) and *graphis* (paintbrush) or *graphê* (drawing) convey the idea of "drawing with light." Light from a scene is recorded on a photosensitive surface, such as chemically treated film or an electronic sensor. In the case of photography, the data are subsequently processed and printed to produce a still image. A photographic image, or photograph, is sometimes called an exposure because the photosensitive surface is exposed to light for a finite duration of time and records only the data available during that exposure time. In the case of cinema, a large number of individual exposures are projected sequentially onto a screen and, from the perspective of the viewer, the result is a moving image—known as a motion picture or movie. *Cinematography* is from *kinesis* (movement). The photographic image typically has just one relevant time constraint: the duration of the exposure time. The cinematic image has other relevant time constraints: in addition to the exposure time, the image is also a function of the speed of the cine-camera—the rate at which frames are exposed—and the projection speed—the rate at which frames are screened.

History of Photography and Cinema

A camera obscura (Latin: *camera*—room, *obscura*—dark) is a darkened room in which light from an outside scene is channeled through a narrow aperture, by lenses and mirrors, to form an image on a screen. However, the resulting image is not a photograph; instead, the image we view inside a camera obscura moves in real time on the screen and leaves no permanent record. Artists can produce a hand-traced outline from the image, and light-sensitive surfaces can react to produce a temporary image; but these are not photographs. A photograph occurs when an image produced by exposure to light is fixed and made to persist over time. The process can be entirely chemical or mechanical, so it can occur without human involvement. This led the first practitioners to claim that photography was the "spontaneous" or "automatic" reproduction of nature by itself, and some argued that photography was a discovery rather than an invention. The term *camera* is now used for any mechanical apparatus that records data in this way. A camera typically has three key elements: lens, shutter, and photosensitive surface. The lens, along with an adjustable opening (the aperture), focuses light onto the photosensitive surface. The shutter mechanism opens and shuts to control the duration of the exposure to light.

The Heliograph

In 1826, Joseph Nicéphore Niépce (1765–1833) succeeded in producing a fixed image from a camera obscura by a process he called Heliography (sun-writing). His image of the view from an attic window achieved important status as the first photograph precisely because it is an enduring image created entirely by an exposure of light on a photosensitive surface. Niépce is not considered the sole originator of photography as history recognizes technical contributions from numerous people working independently and simultaneously. As many as 24 individuals have some claim to have invented photography. Two early contributions to the photographic process deserve special note: the daguerreotype and the calotype.

The Daguerreotype

Niépce's 1826 heliograph, *View From a Window at Gras,* required an exposure time of some 8 hours. With the aim of creating a faster exposure time, he shared details of his process with Louis-Jacques-Mandé Daguerre (1787–1851), who took over the project after Niépce's death and gave his name to the resulting process. A daguerreotype began as a sheet of copper, plated with silver and highly polished. The plate was treated with iodine fumes to give it a light-sensitive surface of silver iodine. The first daguerreotype images had an exposure time of 4 or 5 minutes, and the photographic image became visible when the latent image was first treated with mercury fumes, then fixed with a solution of table salt (sodium chloride). The process results in a "direct positive" print, which is extremely delicate and each image is unique. *Still Life (Interior of a Cabinet of Curiosities),* 1837, is thought to be the oldest surviving example. In 1839 the process was made public to the world by the French Academy of Science.

The Calotype, or Talbotype

In England, William Henry Fox Talbot (1800–1877) developed a process he called "photogenic drawing." Unlike the daguerreotype, which produced a single inverted image, Talbot's process involved the creation of a negative on chemically sensitized paper, from which multiple positive prints could be made. He called this image a calotype—from *kalos* (beauty); an example of a calotype negative survives from 1835, titled *Lattice Window Taken With the Camera Obscura.* Calotypes could be multiply reproduced, but, hindered by long exposure times and problems arising from paper texture, the positive prints were usually indistinct. Daguerreotypes offered a superior quality image, with exceptionally sharp detail. For many years the daguerreotype was more popular among the public, particularly for portraiture. However, in 1851 the collodian wet-plate process replaced Talbot's paper negatives with glass plates and speeded up the exposure time. Ultimately, Talbot's negative–positive process proved to be the prototype for the future of commercial and popular photography.

The Stereograph

Throughout the 19th and early 20th centuries, the stereograph, from *stereos* ("solid") and *skopein* ("to look through"), was one of the most popular forms of photography. A stereograph is created by recording two images of a scene, simultaneously, but from slightly different locations. The two prints were placed side by side in a special viewer, one to be viewed by the left eye and one by the right eye. Viewing a stereograph in this way generates an illusion of three-dimensional space. Such was the demand for this format that a stereoscopic camera was produced. Equipped with two lenses, this camera was specifically designed to take two photographs at the same time. This format has subsequently entirely disappeared, not least because the stillness of the scene fails to entertain modern eyes more accustomed to moving images.

The Kinetoscope and Cinématograph

Even prior to the invention of photography, various devices had been designed to produce a moving image from static pictures. A moving picture is, really, an illusion of movement, created when one image is replaced by another in such a short period of time that the human eye registers the change as though it is the movement of an object. This phenomenon is known as "the persistence of vision." Many of the earliest devices used a rotating cylinder to generate a rapid succession of images. The viewer looked at a fixed point through a series of narrow slits in the rotating drum and saw an apparently moving image. These devices were merely entertaining parlor toys, whereas the invention of cinema in the late 19th century owed its origins to a breakthrough from the world of photography.

Two basic elements are essential for cinema: First, we need an apparatus that records a series of images in sequential time order; second, we need an apparatus that screens the series of images in sequential time order. There are numerous different ways to satisfy one or the other of these requirements, but the invention of celluloid photographic film in the late 1880s provided a straightforward way to satisfy both at once. The advent of film caused the birth of cinema, so it is understandable that the term *film* is used, both as a noun and in verb form ("to film"), as an abbreviation for cinema, but not for photography even though film has been the material medium of both. Roll film provided not just a means of recording a sequence of exposures, but, crucially, also a means of controlling the time sequence when screening the images. The innovations leading up to this point show why film provided the breakthrough that led to the cinematic revolution.

The pioneers of photography investigated two approaches for recording a series of time-ordered images: one solution is to have multiple cameras, each making a single exposure at timed intervals; another solution is to have a single camera making multiple exposures one after another. In the 1870s, Eadweard Muybridge (1830–1904) produced a time-ordered sequence of a running horse using a row of 12 cameras. The shutter of each camera was triggered by cotton threads as the horse ran past. In 1874 scientists were able to use a "revolver camera" to record the transit of the planet Venus across the sun. This camera gun, devised for the purpose by César Jules Janssen (1824–1907), made 48 individual exposures around a circular daguerreotype plate.

Inspired by these ideas, Étienne Jules Marey (1830–1904) developed a process he called chronophotography (time photography) in the early 1880s. Marey used a spinning disk in front of an ordinary camera lens. The disk had slots at regular intervals so that a moving subject appeared at a different position every time an open slot permitted an exposure. The result showed the movement of the subject as a series of overlapping images on a single photographic plate. Eventually, Marey designed a camera to produce a series of multiple exposures that did not overlap. To achieve this he required the light-sensitive surface to move for each new exposure, so the medium needed to be flexible and robust. Glass and metal places were unsuitable, but, when celluloid photographic film became available in 1889, Marey was able to produce a short "film" showing the movement of the human hand. A contemporary inventor, Louis Le Prince (1841–1890), patented a 16-lens motion-capture camera in 1886, but this was unsatisfactory as it recorded images from slightly different angles. By 1888 Le Prince had developed a single-lens camera-projector and used this to record exposures at 12 frames per second on paper-based Eastman Kodak film. Fragments of his first motion picture, *Roundhay Garden Scene,* have survived, and Le Prince is one of several figures who are credited with the invention of cinema.

Thomas Edison (1847–1931) invented the kinetoscope in 1894. This was known also as the peep show because images were screened inside a box and viewed by one person at a time. The kinetoscope screened a 50-foot length of celluloid film at 48 exposure frames per second, and the entire show lasted only 13 seconds. In 1895 the Lumière brothers, Auguste (1862–1954) and Louis (1864–1948), unveiled their Cinématograph, which used a film projector to screen films to a group audience. The majority of early films were studies of human or animal movement and, although cinema would very quickly expand into creative and unconventional treatments of the time sequence, the first film audiences were fascinated simply by viewing the moving image of an ordinary event occurring in real time.

Technology and the Control of Time

Photography and cinema are highly dependent on technical apparatus and therefore particularly sensitive to technological progress. Whenever practitioners have reached the limits of existing equipment, they have urgently invented new camera apparatuses and devised innovative means of production. In this way the creative impetus has driven technological progress, but new technical advances have also produced surprising applications. A survey of the most significant technological advances points to one primary technical challenge: the control of time. The production of a photograph has three stages: preparation time, exposure time, and processing time. Technological progress has dramatically altered the time and resources needed for each of these stages.

Film and Film Speed

Early photographers were forced to spend hours working with raw materials to prepare wet-plates. The laborious preparation time for each photograph removed any prospect of spontaneity; plus the size and amount of equipment required was an encumbrance to the photographer. Photography required wealth, leisure time, technical skill, and some degree of physical strength. A pre-prepared dry-plate process was developed in the 1880s, and in 1889 George Eastman (1854–1932) launched the first celluloid roll film. These technical advances dramatically reduced the burden of preparation time and expensive equipment, but also generated an important further advantage: faster film speeds. Film "speed" is a measure of the threshold sensitivity of the film surface. The current international measurement of film speed is the ISO scale. A representative section of the scale (from slow to fast) is: ISO 100, ISO 200, ISO 400, ISO 800. With greater sensitivity, a film is quicker to respond to the available light. Hence as film speed is increased, exposure times can be decreased. Long exposure times require a camera to be securely mounted, but short exposures make it possible to use handheld cameras. Thus by the time the first drop-in film cartridge was marketed in 1963, cameras were cheap, quick, simple to use, and easily portable, making spontaneous photography available in any location and at any moment.

Automation: Shutter, Exposure, and Flash

Exposure times can be reduced by faster film speed, but also by increasing the level of available light. From the 1860s, photographers created additional light by burning highly explosive magnesium flash powder. Flash technology became less dangerous with the invention of the flashbulb in the 1920s, but photographers still needed to activate shutter and flash separately. In the mid-1930s the mechanisms for flash and shutter were made to synchronize, thus providing far greater control over the timing of the photograph. By the 1950s this became a standard feature on popular cameras.

The first cameras were limited by manual exposure times. A photographer removed the lens cap to start the exposure and replaced the cap to finish. The introduction of mechanized shutters provided much greater precision and control and made it possible to work with exposure times far faster than human action allows. By the end of the 19th century, shutter speeds as high as 1/5000th of a second were possible. When combined with roll film, faster shutter speeds also increased the number of separate exposures that could be taken during a given period of time. The fastest modern SLR (single lens reflex) cameras can make 10 exposures per second.

Even with these mechanical aids, photography still required human expertise for judging the optimum exposure time. However, in 1938, Kodak manufactured a camera equipped with a sensor to calculate the exposure time. Combined with the other technical advances, it was marketed as the world's first fully automated camera.

Developing and Printing

Wet-plate photography necessitated that photographs were processed only a short time after the chemicals had been exposed to light, otherwise the image would not be preserved. This made it extremely difficult for a photographer to freely choose the time to take a photograph, a constraint that is evident in the subject matters favored in the 19th century. For example, photojournalism during the American Civil War was limited to images of the battlefield before or after the action took place. Even when dry-plate and film technology made it possible to process photographs after a reasonable delay, photographers were forced to spend long hours in the darkroom to develop film and enlarge prints from the negatives.

In the 1880s, Eastman marketed the first commercial developing and printing service, which gave the public an alternative to this time-consuming occupation. Kodak publicized the service with a now legendary slogan: "You press the button, we do the rest." With the advent of a developing and printing service, photography enthusiasts were free to pursue their hobby in two alternative directions. Many welcomed the convenience of the commercial service, but others saw processing as an integral part of generating their desired final image. This included techniques such as dodging and burning, where light projected through the negative enlarger is selectively blocked, to compensate for areas of overexposure or underexposure in the negative. In the 20th century, photography clubs became enormously popular and provided ample evidence that photographers across the social spectrum were prepared to invest the time required to master the darkroom arts.

The introduction of color film revealed the extent of this trend. Setting aside earlier experimental versions, the first color film was introduced for movie cameras in 1935, followed by a version for still cameras in 1936. The procedures required for developing color film and producing color prints were disproportionately laborious, even for the enthusiast, and the results were typically less successful than commercial prints. Hence, although color photography became increasingly common for the commercial mass market, enthusiasts in photography clubs preferred to print from black and white film, at least until the advent of digital photography in the late 20th century.

Whether processed by a commercial company or in the darkroom at a photography club, there was still a considerable time lag between making an exposure and viewing the printed image. To satisfy demand for instantaneous results, the first "instant" camera was produced by the Polaroid Corporation in 1948. Invented by Edwin Land (1909–1991), the automated process was able to deliver a sepia-colored print within one minute. The mechanism spreads chemicals over the surface of the film and each chemical reacts according to a time delay, so that each layer of the film is processed in the right order. By 1963 the Polaroid camera was able to produce "instant" prints in color.

Digital cameras do not require a chemical developing process, and an electronic image can be viewed immediately on the camera's own LCD (liquid crystal display) screen. The speed with which a photograph can be viewed is highly important because the power of film media does not lie just in its ability to record events, but also in the possibilities for disseminating images widely and quickly. A daguerreotype image could be disseminated only if it was first translated into an engraving, so rapid publication, such as for newspapers, was out of the question. In the present day, it is commonplace for a mobile phone to contain a digital camera, so photographs and video clips can easily be sent around the world within seconds.

Cinematography

The earliest cine-cameras were cranked by hand, so the speed at which exposures were recorded could be uneven. Most early movies were recorded at between 16 and 23 frames per second. However, nitrate-based film was highly flammable and liable to catch fire if projected at low speeds. Movies were therefore often projected at speeds higher than 18 frames per second, and this produced the appearance of accelerated, unnatural action in the moving image. This is because the perceived speed of an event, from the perspective of a viewer, is calculated by dividing the projection speed by the camera speed. At present, when a moving picture is screened at a cinema theater, images are invariably projected at a rate of 24 frames per second. Hence, when old movies are screened, the images appear to move at an absurdly fast pace. In some cases this phenomenon was deliberately exploited to comic effect by cinematographers.

Even when the standard projection speed of 24 frames per second is maintained, from the perspective of the audience, events can be made to occur faster or slower than the real-time event. The phenomena of high-speed photography and time-lapse photography both exploit the principle that the time-span of the recording can differ from the time-span of the screening. A cine-camera typically exposes film at a rate of 24 frames per second. Each frame is exposed to light for half the time and blocked by the shutter for half the time (i.e., each frame has an exposure time of 1/48 of a second). Time-lapse photography makes exposures at an extremely slow rate—this is sometimes called undercranking. If a camera records a 4-hour event by taking an exposure every minute and the exposures are screened at 24 frames per second, then the 4-hour event will be speeded up and appear to last only 10 seconds.

High-speed photography is known as overcranking because it requires the cine-camera to record exposures faster than 24 frames per second. When the exposures are screened at 24 frames per second, the event will appear to take place in slow motion.

The earliest cine-cameras recorded only the data of light from the scene, so until the 1920s, the results were moving pictures without sound: silent movies. In a significant departure from still photography, cinematographers sought to find a way to record sound—and their main problem became how to make the sound synchronize with the visual action. Again, film provided an elegant technical solution: Sound was recorded onto a magnetic strip along the edge of the photographic film. This ensured that an actor's voice would be heard to speak at the same time as his lips were seen to move. In fact, in 1929, the projection speed standard of 24 frames per second was established precisely because this was the optimal speed for the kind of film used for "talking movies" (talkies).

The Digital Future

Many interesting and important questions about photographic technology have arisen since the rapid emergence of digital photography. Digital cameras were designed by NASA in the 1960s for use in satellite photography. In 1981 Sony demonstrated the first consumer digital camera, and since 2003 digital cameras have outsold film cameras.

In a digital camera, light is captured by an electronic photosensitive surface and the data are digitized into binary code. One significant difference is that the wavelength of light is "interpreted" by the camera software, rather than registered as chemical changes in the surface of the film. In early digital cameras this process created an inconvenient time lag between triggering the shutter and recording the data; however, advances in microprocessor technology have subsequently solved this problem.

Digital photography does not, strictly speaking, involve a negative, so it might appear to have ended the dominant tradition of the negative–positive process. In fact, the digital file that stores data performs a function similar to the latent image on a negative because the binary data it contains needs to be accessed and processed in order to produce a visible "print." Postprocessing of an image, using computer software, has replaced the traditional darkroom work of dodging and burning, and has made possible many other manipulations, so it is still possible to spend many hours on an image before the final version is printed or screened.

It is increasingly common for digital photographs to be viewed and stored only on computers, rather than printed on photograph paper. Digital images are stored as binary data in computer files, hence in principle they can be copied, transferred, and saved for an indefinitely long period of time without degrading. However, archivists of digital photographs face the task of constantly updating the existing digital files, otherwise they could be lost as the retrieval technology becomes obsolete.

Unlike fully manual film cameras, digital photography requires electrical power, and a battery provides power for only a finite period of time. Modern photographers are thus subject to at least one time constraint that is different from, but reminiscent of, the problems that faced their predecessors.

Applications of Film and Photography

Film media are thought to hold a privileged epistemic position by virtue of having a guaranteed causal and temporal relation to reality. Each individual image has a causal relation to the light reflected or emitted by real objects in the world at an actual moment in time. Although a highly abstract image may not resemble any recognizable objects, nonetheless that image was caused by capturing the light from particular objects during a particular period of time. This essential characteristic shapes the applications and the value of photography and cinema.

Documentary

Much of the power of film media stems from their having a documentary function and, when viewed as a document of an event, it seems to matter greatly that a photograph or film was actually exposed at the time it appears to have been exposed. Periodically this feature has been emphasized and exploited, or subverted and resisted. There are two strong trends throughout the history of photography: one emphasizes the ideal of an unaltered image, produced without any retouching of the negative or print. The other embraces manipulation and postprocessing as an intrinsic aspect of a photographic image. Associated with the former we find the idea that a photograph stands in a special relation to the specific moment in time when the data were recorded. Nothing is subsequently allowed to add or take away data recorded at that moment. With the latter trend, we find the idea that a photographic image is not straightforwardly a record of a specific moment in time. Rather, it is the product of various processes and decisions that occur over an extended time and include the exposure as only one factor.

Although this debate persists, it is a fact that manipulation has been a feature of photography from the very beginning. The negative of a calotype could be retouched by scratching the surface before a print was made. In 1851, Edouard Baldus joined together parts from 10 negatives to produce a single print, the *Cloister of Saint Trophîme, Arles,* thus challenging the idea that a photograph necessarily represents a single exposure time.

There has long been a demand for additional evidence to verify when, in physical time, a photograph was taken. In 1914 the Kodak "autographic" camera enabled the photographer to write notes directly onto the undeveloped film while it was still in the camera. Later cameras automated the process of time and date stamping each image, and digital cameras record these data as part of the digital file. However, even a time-stamped image is not a guarantee of epistemic authenticity. It is possible for a photographer to reconstruct an event or reconfigure a scene in order to control the image. This, too, has been a feature of photography since its inception. The public did not object when Alexander Gardner (1831–1882) positioned a rifle next to a dead body for his 1863 Civil War photograph *Home of a Rebel Sharpshooter;* yet the 1945 World War II photograph *Marines Raising the American Flag on Iwo Jima* has been attacked following allegations that Joe Rosenthal (b. 1911) had merely photographed a repetition of the original event.

Despite these concerns, from photojournalism to the photo-finish image that gives a race result, we rely on photographs to stand as evidence that an event took place, or provide evidence about visual appearance at a particular time. This is true of formal contexts, such as law courts and passport photographs, and of informal contexts such as the holiday and wedding photographs in a family album. In both public and personal uses of photography, it seems that we use its documentary function on the one hand to highlight change and on the other hand to preserve against change.

Science

The first scientific applications of photography were reference book collections of scientific specimens. For this use photographs were treated simply as a superior substitute for hand drawings. Before long, however, scientists employed photography to make scientific observations that would not be possible by any other means. In particular, photography makes it possible to observe events that occur too fast for human perception and also to observe light from sources too faint for the human eye to detect. These applications require, respectively, very short and very long exposure times.

Muybridge's and Marey's studies of human and animal motion attracted scientific attention, and Muybridge's 1878 series, *The Horse in Motion,* conclusively proved that a galloping horse raises all its hooves off the ground at the same time. In these experiments exposure time was controlled by shutter speed, but to achieve motion-stop photography of much faster objects, electronic flash photography was essential. In 1851 Talbot created the first flash photograph, using the illumination from an electric spark in a dark room. The exposure time was 1/100,000 of a second—far quicker than any shutter action could produce. In 1931 Harold Edgerton (1903–1990) invented an instantly rechargeable flash mechanism he called the stroboscope and produced motion-stop photographs that fascinated the scientific world, including a bullet piercing a line of balloons and the coronet formed by a splashing drop of milk. Exposure times of a billionth of a second are possible, and the sound waves from bullets moving at 15,000 miles an hour have been "frozen" in a photographic image, making photography an instrument for scientific discovery.

As early as 1839 Daguerre produced a photograph of the moon, and astronomers soon understood that the exceptionally faint light from stellar objects could be recorded on film using extremely long exposures. Light that is too faint for the human eye to detect can accumulate over time on a photosensitive surface and eventually produce a strong image. Through photography, it is possible to observe areas of the universe that are invisible even with the most powerful telescopes—and, uncannily, to observe stars that ceased to exist millions of years ago.

Art

The enormous range of artistic movements in film and photography are too many and too varied to detail here, but it is significant that the supposed objectivity of photography, which made it so suitable for recording scientific observations, initially made it seem unsuitable as a basis for artistic work. Even now, despite the photographs exhibited in art galleries and a long tradition of art discourse, there are still figures who deny that it is possible for a photograph to be an artwork. More generally, it is recognized that, although a fully mechanical or automated photograph is possible, many photographs are valued artistically due to the creative contribution and thought processes of the photographer. Henri Cartier-Bresson (1908–2004) encapsulated this idea when he epitomized the composition of his photographs as "the decisive moment." Elsewhere, even stronger claims have been made to support the view that photographs can be an art form: the critic Susan Sontag (1933–2004) went as far as to claim that the passing of time gives aesthetic value to most photographs, however mundane.

The Viewer's Experience

The viewer of a photograph is able to control the amount of time spent viewing the photograph. The viewer of cinema has a significantly different experience. Photographs are, first and foremost, viewed privately. Multiple copies exist and individuals view individual copies in their own time. Cinema, first and foremost, involves a public viewing. The audience shares a period of time together and the duration of the viewing experience is dictated by the projection time of the movie.

Film media have a unique standing among visual media because they are considered to be such a close substitute for a visual experience that they seem more reliable than human memory, or even can be treated as surrogates for memory after time has passed. This along with an idea that every photograph is essentially a *memento mori*—a reminder of the inevitability of death—is condemned as a cliché by critics and psychologists, but it is undeniable that photography retains powerful associations with poignancy, nostalgia, and loss. The experience of viewing a photograph of one's own ancestor, long dead, is commonly felt to be disturbing and moving in a manner that is unlike viewing even the most realistic painting. A photograph, it has been argued, is "transparent" to the scene at the time it was taken; hence when we look at such a photograph, we are genuinely looking back in time.

In our digital, postfilm era, it is no longer strictly correct to characterize photography and cinema as film media. However, film remains an important feature of their shared history. And history shows that, thanks to film and photography, we have gained new and remarkable ways to experience time and we now have a relation to time and the world that would otherwise not be open to us.

FINITUDE

Finitude is the quality of being finite, or having an end. In this sense it can refer to a length of time, a quantity, or a physical space. It is the opposite of infinity.

Finitude in Mathematics

In mathematics, a set of numbers is a "finite set" if the number of elements can be counted and the total represented as a natural number (e.g., a positive integer). A finite set cannot be put into a one-to-one correspondence with a subset of itself (e.g., a set of the numbers 1 through 10 cannot be matched with a set of the numbers 2 through 8). This is contrasted with an infinite set (e.g., a set consisting of all multiples of 2, an infinite set, could be matched in a one-to-one correspondence with a subset consisting of all multiples of 10, since neither the set nor the subset come to an end).

A "finite decimal" refers to a number that comes to an end, such as 1.543. This is contrasted with a "repeating decimal," in which the same digits are repeated infinitely, represented in the format 2.714714714. . . .

Finite Resources

The second law of thermodynamics states that energy cannot be used indefinitely, and that available usable energy is a finite resource. In this sense, the word *finite* is often applied to the supply of the world's natural resources, as in "finite resources" (also called "nonrenewable resources"). Finite resources, such as oil, coal, and natural gas, are produced at a slower rate than they are consumed, and thus will eventually run out.

Finitude in Humans

The finitude of the human lifespan has been a source of many questions and arguments in theology and philosophy. Pascal, using the finitude of human life as an argument for theism, stated that without God, a person's life would be meaningless because he or she would eventually die. It has also been used as an argument for atheism, encouraging people to make the most of their time on Earth, rather than preparing for an afterlife. In his essays, Albert Camus raised many questions about the mortality, and therefore meaninglessness, of human existence, without arguing for or against any particular way of thinking.

Martin Heidegger wrote that when a human being accepts his or her eventual death is the point when the essence (a human's knowledge of his or her own existence) is brought into focus. This finitude gives human beings a drive to live a productive life and accomplish things before their time is up.

Finitude has also been used to refer to the limits of human knowledge and potential: Unlike the God of the Judeo-Christian tradition, who is infinite and omniscient, human beings cannot objectively know reality and truth. This is reflected in the bible verse I Corinthians 1:25, in which the apostle Paul writes, "God's foolishness is wiser than human wisdom."

Flashbacks

Flashbacks, also known as "intrusive recall," are traumatic memories, thoughts, and pictures from a past event that reoccur in the present when triggered by incoming sensory data. There are four categories of flashbacks: (1) nightmares or dreams; (2) dreams from which the person awakens but remains under the influence of the dream so as to be out of touch with reality; (3) waking flashbacks, in which the person may or may not lose touch with reality but also may have accompanying reactions and hallucinations; and (4) unconscious flashbacks, in which the person is unaware that he or she is reliving the traumatic event and there appears to be little or no connection between past event, present context, and flashback.

Flashbacks act like a video loop in the brain that replays the "recorded material" as if for the first time in its intensity. Flashbacks can take the pictorial form of the original events or present as reactions that accompanied the original traumas, with emotions such as dread, grief, horror, anger, or helplessness. Triggers of flashbacks are reminders of the trauma. They occur in the present tense and often are time-related dates and events, such as anniversaries of the trauma, holidays, and funerals; or an encounter with someone who was the source of abuse. Triggers also can be any stimulus that may have been present within the context of the original trauma, such as sounds that imitate the original sound of the ensuing trauma, or sights, smells, and tastes that were present at the time of trauma or that remind the person of the trauma. A flashback may psychologically paralyze the person and render him or her unable to carry on normal activities temporarily, or over the long term.

Sometimes, the trauma is literally "unspeakable." The brain's inability to respond cognitively and rationally to irrational events causes the brain to "short-circuit." The trauma is recorded within the brain as a whole, but cannot be accessed from the usual cognitive logical sources in the left hemisphere because it is so irrational. The event is nevertheless also recorded in pictorial form in the opposite hemisphere. Indelibly imprinted as images, the event is repeatedly reaccessed in the brain's attempt to assess and process the experience. In flashbacks the brain is revisiting the scene in order for understanding and healing to begin. In this respect the flashback can be thought of as a normal function in a dysfunctional or malfunctioning situation, to make logical sense of what is otherwise incommunicable. In some cases, the trauma is so great, or the time at which it happened so strategic, such as in youth, that the brain cannot accomplish the necessary restructuring of the event without adequate help. Flashbacks continue as a release of the internal horror the person feels.

Physiologically, trauma overwhelms the brain's ordinary responses to life and chemically changes the expressions the brain responds with. It stops the healthy normal interaction of right and left hemisphere so that the victim cannot access the helps needed to overcome the trauma. This process is an actual brain wound that causes a breakdown of functionality. Thus, a course of therapy that approaches trauma wounding from the right hemisphere of the brain, that is, intuitively and creatively, often sidesteps the chemically changed processing ability of the brain's left hemisphere by accessing a different set of communication methods. Often, therapeutic art-making literally can help "draw out" the trauma so it finally can be verbalized. Through this process and other integrative therapies, the hemispheres of the brain eventually may reconnect healthily as the memory-pictures are processed, and flashbacks cease.

Flaubert, Gustave (1821–1880)

Gustave Flaubert was a French novelist noted for his mastery of the realist style of writing and his pervasive irony. His most famous work was the novel *Madame Bovary* (1857), which describes the adulterous, discontented life of a provincial wife. The book's scandalous nature landed Flaubert in court on the charge of immorality, of which he was acquitted.

Flaubert influenced many other writers, including Joseph Conrad and the Italian novelist Giovanni Verga, who imitated his descriptive, realistic style. Flaubert is known to have agonized over the wording of every sentence he wrote. With this careful, meticulous approach, Flaubert developed a new school of writing known as realism, a style in which the author attempts to portray real-life scenarios as they are. The narrator does not judge the character, but leaves the reader to do so. Flaubert's novels often contained mediocre, even miserable characters. He strove to portray them as vividly as possible, with details that shocked French society at the time.

Though Flaubert came from a family of doctors, he harbored a strong contempt for bourgeois society, which is reflected in his work. He was highly critical of the vanity and pettiness that he considered prevalent in society. Flaubert is also known for his extreme nihilism, in that he saw human life and time as empty and meaningless.

Gustave Flaubert was born in Rouen, Normandy, the son of a successful surgeon. During the 1840s he briefly studied law in Paris but failed his second-year exams. In 1844 he suffered a nervous attack, which led him to reevaluate his life and pursue a career in writing. During that time he also had an intimate relationship with the writer Louise Colet. After leaving Paris in 1846, Flaubert settled in Croisset, near Rouen. In 1848 he visited Paris and witnessed the February Revolution there, which gave rise to the Second Republic.

Flaubert's most notable works include *Salammbo* (1862), a tale set in ancient Carthage, which he wrote following a visit there. He was awarded the Legion of Honor by Napoleon III shortly thereafter. He also wrote *A Sentimental Education* (1869), a story that deals with cynicism and doubt.

Flaubert wrote this book to critique the failures of bourgeois society.

In *The Temptation of Saint Anthony* Flaubert demonstrates his deep interest in time and religion. The book is written as a play in which the protagonist, Saint Anthony, resists a succession of temptations during one night of prayer in the Egyptian desert. The early medieval Christian hermit stands firm against the Devil's temptations, which come in various forms. Flaubert researched extensively for the book, reading 134 titles, in French and in Latin, on subject matter dealing with the ancient and medieval worlds. Flaubert worked on this book throughout his life, an attest to his perfectionist nature, and published a final version in 1874.

Some critics have classified Flaubert's work with the romantic movement for its concern with the decadence of Western culture over time. Indeed, Flaubert viewed contemporary French society as vain and self-indulgent. He resisted labels, however, placing greater emphasis on style. Later in life, Flaubert became increasingly reclusive and rarely left Croisset, though he maintained correspondence with friends, including George Sand and Emile Zola. Following years of declining health, Flaubert died of a cerebral hemorrhage in 1880, leaving his final novel, *Bouvard et Pecuchet,* unfinished.

FORAMINIFERS

The foraminifers or foraminifera (forams for short) are a group of ameoboid single-celled protists belonging to the class Foraminifera, phylum Granuloreticulosa, and kingdom Cercozoa. Typically they are microscopic in size and studied by the paleontological branch called micropaleontology. They are also one of the main micropaleontological groups because they can be used to give accurate relative dates to rocks, among other utilities.

Characteristics

Modern foraminifers are primarily marine, although they can survive in brackish conditions, and a few species survive in fresh waters. They have two modes of life, planktic (marine floaters) or benthic (seafloor dwellers). About 275,000 living and fossil species have been recognized. The foraminifers are usually less than 1 millimeter in size, but some are much larger. The largest recorded specimens reached 19 centimeters. They are closely related to the Radiolaria, which also includes amoeboids with complex shells.

The foraminifers typically produce a shell, or *test,* some becoming quite elaborate in structure. The test can have either one or multiple chambers, with the multichambered forms being more frequent. Adjacent chambers are separated by septa. Most have calcareous tests, composed of calcium carbonate (calcite, aragonite), but others may have organic, agglutinated, or silica tests. The organic tests are composed of protinaceous mucopolysaccharide. The term *agglutinated* refers to tests formed from foreign particles (coccoliths, diatoms frustules, microfragments of mollusk and echinoderm, sponge spicules, quartz, mica, magnetite, or garnet), glued together with a variety of cements (organic, calcareous, or siliceous). The calcareous and siliceous tests are secreted. Calcareous tests may be again subdivided into three major types: microgranular (composed of equidimensional subspherical calcite crystals smaller than 5 microns), porcellaneous (composed of thin inner and outer veneers enclosing a thick middle layer of crystal laths), and hyaline (composed of lamellas of calcite crystals larger than 5 microns, which may be equidimensional or radiate).

The name *foraminifera* is derived from the foramen, the connecting hole trough the septa between each chamber. The living foraminifers have reticulating pseudopods (reticulopodes) used for locomotion, for anchoring, and in capturing food. The opening by which the pseudopods access the outside is called the aperture. A bidirectional cytoplasmic flow along these reticulopodes carries granules, which may consist of mitochondria, digestive vacuoles, vacuoles containing waste product, and even symbiotic dinoflagellates. For this reason, the pseudopods of foraminifera are also called *granoreticulopodes*. Foraminifers normally feed on diatoms, bacteria, and copepods. Many species have unicellular algae as endosymbionts, such as dinoflagellates, green algae, red algae, golden algae, and diatoms. Some foraminifers are kleptoplastic, retaining chloroplasts from ingested algae to conduct photosynthesis.

Uses in Science and Technology

The reason why foraminifers are so useful in micropaleontology is that their tests are easily fossilizable and very abundant in the fossil record. Because of their diversity, abundance, and complex morphology, fossil foraminiferal assemblages are useful not only in biostratigraphy and geochronology, but also in paleoenvironmental reconstruction, paleoclimatology, and paleoceanography. The oil industry relies heavily on foraminifers in finding potential oil deposits.

Classification

The traditional classification of foraminifera is based on the composition and morphology of their tests. The primary characters used in these classifications are mainly the following: wall composition and structure, chamber arrangement, the shape and position of the apertures, and surface ornamentation. At species level, other morphologic features are also used, such as the test shape, chamber shape, number of chambers, and so on. The commonly accepted classification of the foraminifera is based on that of the 1987 classification by Loeblich and Tappan, although molecular data and cladistic analysis suggest that this classification may vary substantially in the future. Foraminifers were initially considered to be an order in the class Rhizopoda, phylum Protozoa, of which 12 suborders were distinguished. Today, they are considered as class Foraminiferea, of which 14 orders are distinguished: Allogromiida, Astrorhizida, Lituolida, Trochamminida, Textulariida, Fusulinida, Spirillinida, Carterinida, Miliolida, Lagenida, Robertinida, Globigerinida, Buliminida, and Rotaliida.

The foraminifera have a geochronological range from the earliest Cambrian to the present day. Order Allogromiida (before suborder Allogromiina) includes foraminifers with organic tests, such as *Allogromia*. They are difficult to fossilize and do not have much paleontological interest, but include the ancestor from which evolved all the other groups of foraminifera. They are known from the Cambrian, although probably appeared in the Precambrian. Foraminifers with hard tests were scarce during the Cambrian, Ordovician, and Silurian.

Agglutinated forms were initially included in the suborder Textulariina, but they are now classified in several orders: Astrorhizida, Lituolida, Trochamminida, and Textulariida. They may be composed of randomly accumulated grains or grains selected on the basis of specific gravity, shape, or size. All species are benthic in mode of life. The textularinids first appeared in the Cambrian, 525 million years ago, evolving from organic allogromiinids. Earliest agglutinated species were single chambered; the multichambered varieties evolved 20 million years later. They flourished in the Cretaceous, culminating in the large conic or concave–convex tests of the orbitolinids, such as *Orbitolina, Palorbitolina,* or *Dictyoconus*. They are significant biostratigraphic markers of the Cretaceous in prereef sublitoral paleoenvironments.

The order Fusulinida (before suborder Fusulinina) includes microgranular calcitic forms. All species were benthic. They first appeared in the early Silurian, more than 430 million years ago (mya), probably evolving from some ancestral textularinids. The fusulinids began to be very abundant in the Devonian, culminating in the complex test forms of the Late Carboniferous and Permian times, such as *Fusulina, Schwagerina,* or *Triticites*. They are very important biostratigraphic markers of the Carboniferous and Permian in sublitoral paleoenvironments. They were extinguished in the Permian-Triassic boundary event.

The porcellaneous foraminifers are included in the order Miliolida (before suborder Miliolina). Their first appearance occurred in the latest Devonian or Early Carboniferous, 360 mya. They probably evolved from microgranular fusilinids, modifying the wall microstructure. Three major groups may be recognized: milioloids, soritoids, and alveolinoids, all of them benthic dwellers of sublitoral paleoenvironments. The first ones have the known milioline coiling (spiral coiling), rotating in such a manner that between the median planes of consecutive chambers various angles are produced, for example, 72° (*Quinqueloculina*), 120° (*Triloculina*), or 180° (*Pyrgo*). The soritoids, such as *Orbitolites* and *Sorites,* have cyclical arrangements (arrangement of cyclical chamberlets in one plane or in concentric layers). Finally, the alveolinoids include milioline or planispiral forms, such as *Lacazina* and *Alveolina.* The miliolids flourished in the Late Cretaceous and Eocene, periods for which they are important biostratigraphic markers. Although both groups were considered unrelated in the past, Miliolida today includes the suborder Silicoloculinina, foraminifers with siliceous tests and of scarce paleontological interest.

The most diversified group of foraminifers is the old suborder Rotaliina, today subdivided in two orders: Buliminida and Rotaliida. The rotalinids appeared in the Triassic, more than 249 mya, and diversified in the Jurassic. They are benthic, although some exhibit planktonic stages, and display hyaline tests. The morphology of rotalinids tests varies enormously. Some are small foraminifers (microforaminifera), with serial arrangement (chambers arranged in one [uniserial], two [biserial], or three [triserial] rows), such as *Bolivina, Turrilina,* or *Bulumina;* or with spiral coiling, such as *Discorbis, Nonion,* or *Cibicides.* Others are much larger (macroforaminifers), with orbitoid arrangement (annular series of equatorial chamberlets covered on both lateral surfaces by lateral chamberlets), such as *Orbitoides, Discocyclina,* and *Lepidocyclina;* or with planispiral coiling, such as *Nummulites, Assilina, Operculina,* and *Heterostegina.* The rotaliinid macroforaminifers had two radiations in the late Cretaceous and Eocene–Oligocene, periods in which they are very important biostratigraphic markers together with alveolinids.

The earliest foraminifers are all benthic, and the planktonic forms do not appear until the Middle Jurassic. These forms evolved from hyaline rotalinids that display a meroplanktonic mode of life (i.e., benthic with planktic stages). All planktic foraminifera are included in order Globigerinida (before suborder Globigerinina). The greenhouse conditions of the Cretaceous caused a major diversification of the globigerinids, appearing in large and complex forms such as *Globotruncana, Contusotruncana,* or *Racemiguembelina.* The Cretaceous/Tertiary mass extinction affected more than 90% of the latest Cretaceous planktic foraminifers; surviving scarce species consist mainly of *Guembelitria.* A rapid radiation of planktic foraminifers occurred during the Paleocene, with the appearance of planktic globigerinid and globorotalids. The best Cenozoic planktic foraminifera are *Globigerina, Orbulina,* and *Globorotalia,* but these genera appeared in the Late Paleogene and the Neogene. The planktic foraminifera are the most interesting biostratigraphic markers of the Cretaceous and Cenozoic in the pelagic environment.

Other foraminifer groups are less abundant and interesting, but worth mentioning. All of them are benthic and live to the present day. The order Lagenida included planispiral to uniserial foraminifers with radiate hyaline tests, such as *Nodosaria, Dentalina,* or *Lenticulina.* They appeared in the Late Silurian, evolving from extinct fusulinids or ancestral miliolids, and diversified in the Late Triassic and Jurassic. The order Spirillinida has a test constructed of an optically single crystal of calcite, appeared in the Late Triassic (evolving from extinct fusulinids), and include the old suborders Spirillinina and Involutinina (these latter have a two-chambered test composed of aragonite). The order Robertinida also has a test composed of aragonite and evolved in the Middle Triassic, probably from agglutinated texturalinids; they are the probable ancestor of benthic Rotaliina and planktic Globigerinina. The order Carterinida includes foraminifers that secrete spicules of calcite to form the test; they probably appeared in the Eocene, evolving from texturalinids.

Forces, Four Fundamental

According to the standard model of elementary particle physics, all forces acting in nature can be traced back to four fundamental interactions. These are gravitation, the weak, the strong, and the electromagnetic force. Each one of these four forces has an individual coupling strength and distance dependence. Furthermore, they differ with respect to the properties of the elementary particles they act on. It was among the very first acts of nature to set up the fundamental forces. Within only 10^{-12} seconds after the beginning of space and time presumably unified one single force was successively split up into the four forces that are known today.

In the modern quantum field theory frame, the fundamental forces are described by the exchange of mediatorial particles, so called *gauge bosons*. The electromagnetic repulsion of two identically charged particles, for example, is mediated by interchanged photons in this theoretical framework.

The electromagnetic force acts between particles that carry electric charge. There are two types of electric charge: "positive" and "negative." Charges of identical signature repel one another, while those of different signature attract. The electromagnetic force is responsible for the structure of matter above the molecular level and dominates the physics of our macroscopic environment. It determines chemistry, that is, the physics of the electron sheath and its interactions with atoms and molecules. It causes the impenetrability of solid bodies and allows for action potentials that initiate and regulate muscular motion in the human body. The electromagnetic force between two charges declines with the square of their distance ($1/r^2$).

The strong interaction or force is acting in atomic nuclei consisting of more than one proton (which carries a positive electrical charge); the chargeless neutrons have to be stabilized against electromagnetic repulsion. This is the main task of the strong interaction, which acts around 100 times stronger than the electromagnetic force at very short distances. The strong force is also responsible for the inner coherence of the nucleons (protons and neutrons, the particles constituting atomic nuclei) as well as all particles that are composed of *quarks*. The strong force has an extremely short range (10^{-15} m) and is mediated by so-called *gluons*.

The weak interaction or force, like the strong force, has a very short special range of influence (10^{-18} m). It plays an essential role in radioactive decay and the complex fusion processes acting as energy sources within the stars. During the first minutes of the universe it was a major regulating factor in establishing the number density of neutrons, which again determines the cosmic abundance of hydrogen and helium. The weak force has a relative strength of 10^{-13} compared with the strong force. The mediator particles are the very massive bosons W+, W–, and Z0, first detected in 1983 at one of CERN's (European Organization for Nuclear Research's) particle accelerators.

Finally, gravitation, with a relative strength of 10^{-40}, is by far the weakest of the four fundamental interactions. It is nevertheless responsible for the orbits of the moon and the earth, the dynamics of the solar system, and the large-scale structure of the universe. This apparent contradiction—the weakest force dominating on the largest scales—can be explained by two facts: the first is that gravitation, like the electromagnetic force, has an infinite spatial range. Second, gravitational forces cannot be cancelled by an opposing force. Thus the effect of gravity can in fact spread over very large distances. Today it is the only fundamental interaction that does not have a theoretical description in quantum mechanics. Its mediator particle, the graviton, is therefore still hypothetical. According to Einstein's general theory of relativity, gravitation is understood as intrinsic to the curvature of spacetime.

Immediately after the big bang, at the beginning of time when the universe had a temperature of 10^{32} Kelvin, the fundamental forces are believed to have been perfectly unified into one force called *quantum gravity.* During only the first 10^{-12} seconds after the big bang, the individual interactions—first gravity, followed by the strong force and then the electromagnetic force—separated from a decreasing level of unification and then finally the weak interaction broke away, resulting in the four forces of nature known today.

Fossil Fuels

Fossil fuels—coal, natural gas, and petroleum—provide an invaluable and still readily available source of energy. Application of these fuels is wide ranging, from heating homes to powering jet aircraft. The fuels are found beneath the earth's surface, and were formed from plant and animal remains dating back 300 million years. To obtain energy from this raw form, the fuels must be burned to release the chemical energy present within the resource.

Given the vast time necessary for biological remains to accumulate and create this sort of fuel, they are not practically renewable, as it would take millions of years to resupply the world's constantly depleting reserves. Most of these reserves can be found in the Middle East (e.g., Saudi Arabia, Iran, Iraq), and also in Canada and Russia. Because the fuels are so vital to present-day society, it has become necessary for able nations either to stake a physical claim in these parts of the world, or to engage in diplomatic and strategic alliances so as to ensure continued access to this necessary commodity.

Only recently has humankind begun to harness the power of fossil fuels to any appreciable extent. Although coal was used by ancient humans, there was no concerted search for it; instead, early humans stumbled upon it by chance. During the Industrial Revolution of the late 1700s, coal became the main source of energy, displacing wood charcoal. Currently, it is estimated that there are approximately 240 years of coal remaining if consumption rates remain the same as today.

The oil industry is less than 150 years old, yet based on present consumption rates there are only 42 years of proven reserves remaining worldwide. Drilling for oil originated in 1859 when the Pennsylvania Rock Oil Company became interested in drilling for natural oil so as to eliminate dependency on expensive whale oil used for heating and illumination. At present, the oil industry is the largest industry in the world, generating around $100 billion annually.

Unlike oil and coal, natural gas (in its original state) cannot be stored and transported in containers. Instead, it must be piped from producing fields directly to the end user. At present usage rates, there are approximately 60 years remaining of proven natural gas reserves. Of the three fossil fuels, gas is by far the cleanest burning, as it emits mostly water vapor and carbon dioxide (CO_2), although significantly less CO_2 than both coal and oil. It is CO_2 that is widely credited with trapping heat beneath the earth's ozone layer, thus leading to what is commonly referred to as global warming.

Ironic as it may seem, the existence of present-day civilization is heavily dependent on these products that are millions of years old. If fossil fuels were to disappear overnight, modernity would be crippled. As such, the current era must recognize that its progression has been possible only by a strong linkage to the ancient past through this invaluable source of energy. Given its apparently short-term viability, alternative means of energy—such as geothermal, nuclear, and solar—are aggressively being developed, eventually to provide for a gradual and, it is hoped, relatively calm switch as humanity weans itself from fossil fuels.

Fossil Record

The fossil record is the set of remains or traces of past organisms identified in fossiliferous rock formations and sedimentary strata (the stratigraphical record) from previous geologic ages to present. Both stratigraphical and fossil records constitute the geological record. The fossil record, or paleontological record, is a primary source of information for evaluating the history of life, including evolutionary processes and extinction events. Paleontologists have studied the fossils of many thousands of species that lived in the past. They have identified evolutionary successions through time, manifesting the morphological transitions from some species to others.

The fossil record confirms a basic prediction of evolutionary theory: *the past organisms were quite different from present ones*. Furthermore, the farther back in geological time we look, the simpler and more morphologically similar are the larger taxonomic groups that became fossilized, precisely what to expect if the hypothesis that all life on Earth originated from a universal common ancestor were true. Other features are observed in the fossil record that provide evidence for evolutionary theory: transitional fossils between ancient species and more modern ones, consistent hierarchy in homologies and analogies of past organisms, paleobiogeographic data that show that proposed descendants appeared in the same general area as their predecessors, and so on. Exceptional outcrops containing very well-preserved fossils of past fauna and flora, what is called a *Konservat-Lagerstätte,* have been found worldwide for the different geological time periods and epochs.

Archean Fossil Record

The oldest fossil traces are the stromatolites of 3,500 million years ago (Paleoarchean era, Archean eon). The stromatolites consist of attached, lithified growth structures, accretionary away from a point or limited surface of initiation. The result is a laminated rock built of layer upon layer of sediment and precipitants. The stromatolites are formed by the trapping, binding, and cementation of sedimentary grains by microorganisms, especially cyanobacteria. The first stromatolites were probably built by green sulfur-bacteria and purple bacteria, and they were not very abundant. However, the stromatolites became common during the Paleoproterozoic and Mesoproterozoic eras (early and middle Proterozoic eon, between 2,500 and 1,000 million years ago [mya]), due probably to the great proliferation of colonial cyanobacteria.

The first putative fossil bacteria were found in a stromatolitic formation from the Warrawoona Group (Western Australia) of 3,460 mya. They seem to belong to the domain Eubacteria, but microfossils of extremophilic domain Archaea have also been identified in the Archean eon. Archean life was surely limited to simple nonnucleated single-celled microorganisms, or prokaryotes (bacteria). There are no known eukaryotic fossils in Archean rocks, although they might have evolved then and simply not left any fossil. Cyanobacteria and oxygenic photosynthesis first evolved in the Mesoarchean era (3,200–2,800 mya), and were common during the Neoarchean era (2,800–2,500 mya). The combination of oxygen released by photosynthetic cyanobacteria and dissolved iron in oceans formed a distinctive Archean (and Proterozoic) type of rocks, called banded iron formations.

Proterozoic Fossil Record

Pre-Ediacaran Time

While it was involved in oxidizing the oceanic iron and precipitating banded iron oxides (magnetite), biogenic oxygen could not be accumulated in the atmosphere, which continued to be a reducing environment, containing less and less oxygen. This geological process ended in the Proterozoic eon. At that time, the progressive accumulation of oxygen in the atmosphere might have caused the extinction of numerous groups of anaerobic bacteria, what sometimes has been called the oxygen catastrophe of the Paleoproterozoic era (2,500–1,600 mya). It is considered that the atmosphere changed to oxygen-rich during the Orosirian period (2,050–1,800 mya), since the banded iron formations were abundant in the previous periods, mainly during the Siderian period (2,500–2,300 mya) but also during the Rhyacian period (2,300–2,050 mya).

A major event in the history of life occurred at the beginning of the Statherian period (1,800–1,600 mya): the evolution of the eukaryotic cell. Unlike prokaryotic cells, the genetic material of the eukaryotes is organized in a membrane-bound nucleus. Moreover, eukaryotic cells have a variety of internal membranes and structures, called organelles (mitochondria, chloroplasts, endoplasmic reticulum, Golgi apparatus, etc.), and an inner cytoskeleton that includes motile cytoplasmic projections (pseudopods, flagella, and cilia) and other structures (e.g., centrioles). The origin of the eukaryotic cell is disputed. It is believed in general that the nucleus and the internal membranes derived from the invagination of the plasm membrane (F. J. R. Taylor's autogenous model), whereas mitochondria, chloroplasts, centrioles, flagella, and cilia evolved from certain types of eubacteria that a group related to the archaeobacteria engulfed through endophagocytosis (Lynn Margulis's endosymbiotic model). Sphaeromorph microfossils (assigned to acritarchs) from the 1,800-million-year-old Changshoigou Formation (Jixian, north China) are interpreted as probably representative of first unicellular eukaryotic protists.

During the Mesoproterozoic era (1,600–1,000 mya) another major event in the history of life occurred: the evolution of sexual reproduction. It has been suggested that cannibalism by primitive protists (protogametes) in times of starvation could have led to a stalemate, with cells becoming fused (protofecundation) but eventually separating when the environmental conditions improved (protomeiosis). The cannibal fusion of cells during conditions of environmental stress was accompanied by the formation of cysts. Cysts are resistant structures, sometimes mineralized, that become preserved in the fossil record. The first fossil group with sexual reproduction is thought to be the acritarchs, known from at least 1,400 mya; that is, approximately at the boundary between the Calymmian and Ectasian periods. The acritarchs were single-celled organisms (protists) that included a wide range of different taxonomic groups. Some acritarchs might be cysts of unicellular algae that were ancestors of the dinoflagellate (a large group of flagellate protists). Microfossils attributed to clear dinoflagellate have been found in 1,100-million-year-old rocks (Stenian period, which lasted from 1,200 to 1,000 mya). Other acritarchs might be related to the prasinophycean green algae (probable unicellular ancestral stock from which descended all other green algae and later the plants). Clear microfossils of green algae or chlorophytes were identified in 1,000-million-year-old rocks.

Fossil evidence of eukaryotic red algae or rhodophyte (*Bangiomorpha*) has been identified in the transition between the Ectasian and Stenian periods (approximately 1,200 mya), in the Hunting Formation (Somerset Island, Canada). This is the earliest known complex multicellular organism. The development of sexual reproduction in unicellular protists might have precipitated the evolution of multicellular life. The multiplication of cells in the first multicellular organisms could occur in the interior of a resistant cyst after fecundation and before meiosis.

The eukaryotic cell, sexual reproduction, and multicellular eukaryotic organisms could have had an early evolution. Because the first organisms would not have had hard parts, the first unicellular and pluricellular eukaryotic organisms are probably not preserved in the Archean and Proterozoic fossil record. It is hypothesized that these three significant milestones in the history of life were developed very early. For example, the first eukaryotic cells could have appeared 2,700–2,100 mya, coinciding with the release of atmospheric oxygen; and sexual reproduction could have developed at least 1,800 mya, the age of the first possible acritarchs in China. Moreover, 1-meter-long fossil tubes called *Grypania* were identified in 2,000-million-year-old rocks of Lake Superior and have been attributed to unicellular eukaryotic algae, although also to giant bacteria.

The Neoproterozoic era (1,000–542 mya) covers one of the most interesting times in the history of life and the fossil record, such as the development of complex multicellular organisms and the appearance of animals or metazoans. Different lineages of eukaryotic protists also evolved during this era. The first radiation of acritarchs occurred during the Tonian period (1,000–850 mya). The first fossil record of ciliates and testate amoebae occurred more than 750 mya, that is, in the Cryogenian period (850–630 mya). This period is characterized by worldwide glacial deposits, suggesting that during this time Earth's climate suffered the most severe ice ages in its history (Sturtian and Marinoan glaciations). It has been hypothesized that planetary oceans were frozen over completely (the Snowball Earth hypothesis).

In spite of the fact that the acritarchs suffered a significant mass extinction event during the cold Cryogenian period, the development of multicellular animals may have been favored due to increased evolutionary pressures during the multiple icehouse–hothouse cycles of the Cryogenian period. Animals are generally accepted to have evolved from choanoflagellates, collared flagellate protozoa that have the same structure as certain sponge cells. Using nuclear-encoded protein sequences, geneticists and molecular biologists have suggested that the appearance of animals occurred as early as 1,200 mya (the Mesoproterozoic era). However, a conflict between these molecular models and the traditional perception of the fossil record makes some paleontologists wish to reconsider the molecular data. In spite of this criticism, the Proterozoic fossil record is supplying new, unexpectedly complex life forms probably related to multicellular metazoans: enigmatic bedding-plane impressions (*Horodyskia*) of colonial benthic eukaryotic organisms living 1,500 mya (Calymnian period from the Belt Supergroup of Montana); fossils of worm-like segmented organisms (*Parmia*) in 1,000-million-year-old Tonian deposits in Timan (Russia) and interpreted as a probable predecessor of the annelid worms; and macroscopic fossils of worm-like organisms (*Protoarenicola* and *Pararenicola*) discovered in 740-million-year-old Cryogenian deposits from Huainan (China) and related probably to annelids and pogonophorans.

Ediacaran Fossils

The end of the global glaciations of the Cryogenian period occurred 630 mya, and after it came one of the most interesting periods in the evolution of life: the Ediacaran period (635–542 mya), also called the Vendian period. This period is characterized by a group of ancient life forms called Ediacaran or Vendian biota. This fauna is older than the oldest shelled fossils of classical paleontology: the Cambrian faunas. Its first fossil record was found in the Ediacara Hills Konservat-Lagerstätte (South Australia). Dozens of outcrops with related fossils have been found since then, especially important being the deposits found in the White Sea (Russia), in southwestern Africa, in northwestern Canada, and in southeastern Newfoundland. Another significant Ediacaran Konservat-Lagerstätte deposit was found in the Doushantuo Formation (Guizhou, China). In addition to bacteria, protists, and algae fossils, the Ediacaran fossil record includes the oldest definitive multicellular animals. They are generally segmented or frond-like organisms, and many of them are difficult to interpret. Some have been redescribed as trace fossils, such as *Dickinsonia,* and often interpreted as ancestral arthropods; forms such as *Spriggina* can resemble trilobite traces. Ediacaran organisms include frond-like forms called *rangeomorphs;* they have disk-type morphologies with various ornamentations (e.g., *Charniodiscus* and *Charnia*). They could belong to cnidaria (related to modern sea pens) or be possible precursors of arthropods and mollusks. Various disk-like forms could be also related to anemones (e.g., *Mawsonites*) or sponges (e.g., *Palaeophragmodictya*). Nevertheless, many of the best-known Ediacaran creatures appear to have no obvious relationship to later metazoans, including organisms that resemble sessile bags, annulate disks, and air mattresses. An alternative interpretation is to consider that these extinct organisms belonged to a new separate kingdom (kingdom Vendobionta) that comprises nonmetazoan, coenocytic groups, or giant multinucleate eukaryotic unicellulars. These organisms disappeared across the Ediacaran-Cambrian boundary (approximately 542 mya), perhaps wiped out by a mass extinction event.

Phanerozoic Fossils

The Phanerozoic eon (545 million years–present) is a period of geologic time during which abundant hard-shelled animals lived. Its name derives from the Greek and means "visible life," referring to the abundant fossil record. Significant events in the history of life occurred during this eon: rapid radiation of a great number of animal phyla; emergence of terrestrial plants and animals; evolution of complex plants; and evolution of fishes, amphibians, reptiles, and mammals. All of these evolutionary events allowed the development of the modern faunas and floras, although this process was also sprinkled with multiple mass extinction events. Two of these extinction events (Permian-Triassic and Cretaceous-Paleogene events) mark the boundaries between the Phanerozoic eras: the Paleozoic (542–251 mya), Mesozoic (251–65 mya), and Cenozoic (65–0 mya) eras.

Paleozoic: From the Cambrian Explosion to the P-T Extinction Event

Cambrian

The Proterozoic-Phanerozoic boundary (or Neoproterozoic-Paleozoic boundary, or Ediacaran-Cambrian boundary) has been classically placed at the first appearance of trilobites and archeocyathids. These extinct life forms are complex compared with the preceding Ediacaran fauna. A large number of animal groups appeared nearly simultaneously at the beginning of the Cambrian period (542–488 mya), such as mollusks, brachiopods, bryozoans, arthropods, echinoderms, and even vertebrates. There is some fossil evidence that simple life (algae, fungi) may have invaded land in this moment, although plants and animals do not take to the land until the Silurian or Devonian. This rapid episode is known as the Cambrian explosion, and represents the most significant evolutionary radiation to happen in the history of life on Earth. The major groups or phyla of animals emerged suddenly, in most cases without evidence of precursors. The Early Cambrian metazoan radiation was also accompanied by a diversification of organic-walled protists, including prasinophyte and dasyclad green algae, benthic foraminifers, and acritarchs. Exceptional fossiliferous outcrops (Konservat-Lagerstätten) of the Cambrian have been found at Burgess Shale (British Columbia, Canada), Maotianshan Shales (Chegjiang, China), Sirius Passet (Greenland), Orsten and Alum Shale (Sweden), Murero (Spain), Emu Bay Shale (South Australia), Kaili Formation (Guizhou, China), and the House Range (Utah).

The most famous Cambrian fossils are the trilobites, a group of extinct marine arthropods that form the class Trilobita. Many thousands of trilobite species are known, and they serve as excellent Paleozoic index fossils because they evolved rapidly and present a good fossil record. Their ancestors seem to be morphologically similar to taxa like *Spriggina, Parvancorina,* and other trilobitomorphs of the Ediacaran. It is reasonable to assume that the trilobites share a common ancestor with other arthropods that lived prior to the Ediacaran-Cambrian boundary. The most primitive groups appeared during the Early Cambrian and belong to the orders Agnostida, Redlichiida, Corynexochida, Naraoidia, and Ptychopariida. Although the agnostids have the most primitive characteristics, the redlichid trilobites are the first true arthropods to appear in the fossil record. The earliest known trilobite is the redlichid genus *Fallotaspis.*

The trilobites could be related to the chelicerata (spiders, scorpions, and related forms), the Cambrian aglaspids being an intermediate group. Crustaceans also first evolved in the earlier Cambrian, as part of the great radiation of Cambrian coelomate animals. Although the crustaceans have hard exoskeletons reinforced with calcium carbonate, their fossil record is rarer than that of trilobites during the Cambrian.

Arthropods are thought to have branched from an ancestor of the segmented worms, probably prior to the Cambrian, and the onychophorans are a good example. The onychophorans (or velvet worms) are a phylum that today includes segmented terrestrial animals somewhat resembling both annelids and arthropods. Traditionally the annelids have been considered the closest relatives of arthropods and onychophorans, due to their common segmentation. Annelids are known at least as early as the Cambrian, and there is some evidence that they appeared during the late Neoproterozoic (*Cloudina* may be an early serpulid worm fossil of the Ediacaran). They comprise the segmented worms, and include the well-known earthworms, leeches, serpulids, and tube worms. However, the similarities between annelids and arthropods have been more recently considered convergent evolution. The arthropods may be more closely related to certain pseudocoelomates such as nematodes (roundworms) or priapulids (penis worms); further, the annelids are more closely related to mollusks, bryozoans, and brachiopods.

The brachiopods (lamp shells) are sessile, two-shelled, marine animals with an external morphology resembling bivalve mollusks. However, they have a lophophore (a ring of ciliated tentacles surrounding the mouth) similar to that of the bryozoans. Although possible brachiopods have been found in the Ediacaran period, the earliest unequivocal brachiopods in the fossil record occur in the Early Cambrian, appearing first as inarticulate forms (e.g., *Lingula*) followed soon by articulate forms (e.g., *Obollella*). Apart from perhaps the trilobites, brachiopods are one of the most important Paleozoic index fossils. Unlike bryozoans, they are solitary and never form colonies. Together with bryozoans (ectoproctans) and phoronids (horseshoe worms), brachiopods belong to the informal lophophorates and they almost certainly share a common ancestor.

The briozoans are small colonial animals that build skeletons of calcium carbonate, superficially similar to coral. They were initially subdivided in two subgroups, ectoproctans and entoproctans, based on their similar body plans (with lophohore) and mode of life. Nevertheless, the ectoproctans are coelomate (possessing a body cavity) and the entoproctans are acoelemate. Molecular studies do not support a phylogenetic relationship between the two groups. For this reason, the entoproctans are now considered a phylum of their own and related to mollusks and annelids, whereas the ectoproctans are considered synonymous with bryozoans and related to brachiopods and phoronids. The true bryozoans, the ectoproctans, perhaps evolved from a phoronid-like ancestor in the Cambrian, but their first fossil record occurs in the Ordovician period. The phoronids are worm-shaped creatures that secrete chitinous tubes in which to live, and some early Cambrian forms (e.g., *Iotuba*) have been attributed to them.

The earliest mollusk fossils belong to the univalved monoplacophorans. They are probably the ultimate common ancestor of all univalved and bivalved mollusks; they first appeared in the fossil record in the earliest Cambrian. By the Late Cambrian, most living classes of mollusks has been found in the fossil record, including Gastropoda (snails and slugs), Cephalopoda (nautilus, ammonites, squids, octopuses, cuttlefish), and Pelecypoda or Bivalvia (clams, scallops, mussels, cockles). All of them were initially marine. The first true gastropods appeared in the Middle Cambrian (e.g., *Protowenella*) and Late Cambrian (e.g., *Chippewaella* and *Sterpsodiscus*), although some Early Cambrian forms have been related to gastropods (e.g., *Scenella*). The cephalopods also developed during the Cambrian, with the plectronocerids (e.g., *Plectronoceras*) considered the basal group. A little-known but important Cambrian group of mollusks was the helcionellids, such as *Helicionella, Yochelcionella,* and *Latouchella*. They could have affinities with other primitive groups like poliplacophorans (chitons). The Lower Cambrian fossil *Tommotia,* which had squid-like tentacles and a snail-like foot, is considered to be a basal cephalopod.

Many Cambrian taxa do not seem to have any relationship to modern taxonomic categories. *Halkieria* could be an inarticulate brachiopod or at least a stem group, or even represent the procoelomate ancestors of all higher (coelomate body plan) animals, including brachiopods, annelids, and mollusks. The present aplacophorans (small, cylindrical, and worm-like mollusks) could be relics of the original Ediacaran or Cambrian procoelomate-molluskomorph radiation. *Wiwaxia* and *Odontogriphus* have been considered protomollusks, and related to Ediacaran *Kimberella,* which could have also mollusk-type radula. *Orthrozanclus,* a fossil recently discovered at the Burgess Shale Formation (Canada), could be the evolutionary link among mollusks, annelids, and brachiopods. The genera *Halkieria* and *Wiwaxia* have been placed tentatively in a group called Halwaxiida. Other poorly understood Cambrian taxa have been included in an informal Lobopodia family. These include such famous fossils as *Anomalocaris, Opabinia, Xenusion, Amiskwia, Odontogriphus,* and *Hallucigenia*. *Anomalocaris* seem to be closely related to the arthropods. It is included in the collective group named anomalocarids, which also includes *Laggania, Amplectobelua,* and probably *Opabinia*. Some of the lobopodia taxa, such as *Xenusion, Aysheaia,* or *Microdictyon,* are onychophore-like forms. The famous *Hallucigenia* was considered to belong to Lobopodia, but is now considered to be a true onychophoran. Finally, *Amiskwia* could be a chaetognath (arrow worm) or a nemertean (ribbon worm); its affinities are not clear.

Echinoderms also evolved in the Early Cambrian from deuterostome animals with bilateral symmetry, but later acquired their typical pentaradial symmetry. Their larvae are organized in a bilaterally symmetric fashion similar to embryonic chordates. An extinct class of bilateral forms, called helicoplacoidea, includes the earliest fossil echinoderms (*Helicoplacus*), found in the lowest Cambrian fossil record of the White Mountains (California). With scarce exceptions, all extant echinoderms fall into five well-defined classes: crinoidea (sea lilies), asteroidea (sea stars), ophiuroidea (brittle stars), echinoidea (sea urchins), and holothuroidea (sea cucumbers). All of them could have evolved from an extinct Cambrian echinoderm group called homalozoa (*Stylophora, Soluta, Cincta,* and

Ctenocystis), which have been connected to the chordates. *Arkarua,* a small disk-like taxa of the Ediacaran with fivefold symmetry, has been proposed as a possible precursor of the extinct Cambrian asteroidea (edriosteroidea). Echinoderms are a sister group of hemichordates and chordates.

Hemichordates are worm-shaped marine animals—deuterostomes like echinoderms and chordates—that also evolved in the Lower Cambrian. They include a significant fossil group named graptolites. The earliest graptolites are known from the Middle Cambrian, such as *Chaunograptus* of the Burgess Shale Formation (British Columbia, Canada) or *Chepalodiscus* of the Wheeler Shale Formation (Utah). The graptolites were colonial hemichordates, and their fossils resemble hieroglyphs. The graptolite colony, known as a rhabdosome, has numerous individuals (zooids) with theca distributed in a variable number of branches (stipes). Because many graptolites are good index fossils, they are used in Paleozoic biostratigraphic scales. The most primitive graptolites, the dendroids, had many stipes and were generally benthic. *Emmonaspis,* an enigmatic worm-like animal from the Lower Cambrian of Vermont, has been associated with graptolites and chordates.

Chordate origins are not fully understood, although Cambrian Burgess Shale outcrops have some small fossil taxa called *Piakia* with all the ancestral chordate characteristics. It is very similar to the most primitive living chordate, *Amphioxus.* The chordates are distinguished by a notochord, a semiflexible rod running along the length of the animal. This is replaced and surrounded by the vertebra or backbone in the vertebrates. There are three major groups of chordates: urochordata (tunicates), cephalochordata (lacenlets), and vertebrata. *Yunnanozoon,* a suspected chordate or hemichordate similar to the most primitive vertebrate *Haikouella,* was found at the Lower Cambrian Maotianshan shales of Chengjiang (Yunnan, China). *Haikouella* is surely a chordate related to the first agnathans vertebrate.

Vertebrates also started to evolve during the Cambrian explosion. They are chordates with backbone, vertebral or spinal columns, and include fish, amphibians, reptiles, birds, and mammals. Between the first clear vertebrates are fish-type forms like *Haikouichthys* and *Myllokunmingia,* which are probably primitive agnathans related closely to the lampreys. Agnatha are fish-like vertebrates characterized by the absence of jaws and paired fins, and they include such extant groups of jawless fish as lampreys (petromyzontids) and hagfish (myxinids).

Some paleontologists and molecular biologists question the apparent suddenness of the Cambrian radiations, suggesting it is a problem of discontinuity in the fossil record. The Cambrian explosion could represent simply a swift increase of animals with hard parts easily fossilizable. Several modern phyla, mainly those with small and soft bodies, have no fossil record in the Cambrian or any another period of the Phanerozoic. Therefore, the first appearance of those phyla could truly occur in the Proterozoic, but their first forms were made up of soft parts that did not fossilize.

Ordovician

The Ordovician period (488–444 mya) is characterized by shallow epicontinental seas rich in life, particularly trilobites and brachiopods. Corals flourished in the Ordovician, including rugose and tabulate forms. Mollusks became common during the Ordovician, especially bivalves, gastropods, crinoids, and nautiloids. Nautiloids are a group of shelled cephalopods that flourished during the Ordovician, although they evolved in the Late Cambrian (they are first known from the Fengshan Formation, China). Their shells may be straight, curved, or coiled. The straight-shelled nautiloids (e.g., *Orthoceras*) are common in Ordovician limestones from Scandinavian and Moroccan outcrops, and some of them reached large dimensions, as Endoceras (measuring up to 3.5 m in length) and Cameroceras (probably 11 m in length). Exceptional marine Late Ordovician Konservat-Lagerstätte were discovered in the Soom Shale (South Africa), which includes well-preserved fossils of sea scorpions (eurypterids), conodonts, orthocerid nautiloids, brachipods, trilobites, and chitinozoas. Graptolites also thrived during the Ordovician, evolving the first pelagic forms (graptoloids) at the beginning of this period. They are most commonly found in black shales (deepwater, dysoxic facies). Abereiddy Bay (Wales) is a well-known outcrop for Ordovician graptolite fossils. A significant fossil group of jawless fishes appeared in the Ordovician: the ostracoderms (shell-skinned). They were primitive agnathans covered in an armor of bony plates and usually less than 30 centimeters in length. An important evolutionary event that occurred during the Ordovician was the first appearance of terrestrial plants, evolving from green algae (charophyta). Fossil spores from terrestrial plants, probably from bryophites (mosses, hornworts, liverworts), have been found in uppermost Ordovician sediments. The symbiosis between the roots of land plants and fungus (mycorrhiza) occurred surely at the same time, and this mutualistic association is today essential for the growth of the land plants. The Ordovician finished with a series of extinction events (between 444 and 447 mya) that, taken together, comprise one of the five major mass extinction events. About 85% of all species became extinct, causing the disappearance of one third of all brachiopod and bryozoan families, as well as numerous groups of conodonts, trilobites, and graptolites. Much of the reef-building fauna was also decimated. The most commonly accepted theory is that these events were triggered by the onset of a glaciation, causing a progressive fall in sea level and a drastic change of the marine habitats. This ice age ended the long, stable greenhouse conditions typical of the Ordovician.

Silurian

The Silurian (443–416 mya) was a period characterized by high sea levels and warm shallow seas that provided a hospitable environment for marine life. Wenlock Series Konservat-Lagerstätte (UK) contains well-preserved fossils of worms, sponges, graptolites, chelicerates, and mollusks, as well as abundant radiolarians, a protist group that produced intricate siliceous microskeletons. The first appearance of coral reefs occurred in the Silurian, built by extinct rugose and tabulate corals. Trilobites, mollusks, brachiopods, and briozoans were very common and quite diverse. Besides the trilobites, other arthropods began to be diversified. Giant sea scorpions (*Eurypterus, Pterygotus*), some of them more than 2 meters in length, lived during the Silurian, and were formidable predators. Although they are not true scorpions, they are related to the arachnids. The arthropods colonized the terrestrial environment for the first time in the Late Silurian. Among them, the myriapods (millipedes) were surely the first terrestrial animals. The first appearance of terrestrial arachnids occurred in the Late Silurian, and the trigonotarbids (spider-like arachnids) are one of the oldest known land arthropods. Myriapod and arachnid cuticles have been found in Upper Silurian rocks in Shropshire (England). The first true fishes were the acanthodians (spiny sharks), which appeared in the Early Silurian. This extinct group had features transitional between the two main groups of extant fishes, the bony fish (osteichthians) and cartilaginous fish (chondrichthians). Placoderms, armored fishes, are also known from Upper Silurian rocks of China (e.g., *Wangolepis*). The first fossil record of vascular plants or tracheophytes (with specialized tissues for conducting water, minerals, and photosynthetic products) occurs in Silurian rocks, and it includes primitive vascular plants (rhyniophytes) like *Cooksonia* (early Silurian of the Northern Hemisphere). Most evolutionary rhyniophytes (as *Rhynia*) and primitive lycopods (as *Baragwanathia* from the Upper Silurian rocks of Australia) were other vascular plants that appeared in this period.

Devonian

The Devonian period (416–359 mya) continued to be dominated by brachiopods, bryozoans, crinoids, and corals in the marine environment. Great barrier reefs extended a thousand kilometers around the Devonian continents, built by sponges (stromatoporids), corals (tabulate and rugose), and calcareous algae. Trilobites were still very common. Armored otracoderms and placoderms were the most abundant fishes of the Devonian, coexisting with the first sharks and ray-finned fish. The first shark, *Cladoselache,* which appeared in the Devonian, was 1.2 meters in length, and exhibited a strange combination of ancestral and derived characteristics. Placoderms went on to inhabit and dominate almost all known aquatic ecosystems, including freshwaters. Canowindra (New South Wales, Australia) is a Konservat-Lagerstätte that contains excellent fossils of fishes, including placoderms and lobe-finned crossopterygians. Originating from within the nautiloid, the ammonites first appeared in the early Devonian. The ammonoids are excellent index fossils for the Upper Paleozoic and Mesozoic. Their shells usually take the form of planispirals, although some of them were trochospiral (helicoid) or nonspiraled. The most primitive group of ammonoids is the goniatitids, which were superficially similar to the nautiloids. Excellent lagerstätte-type outcrops with well-preserved marine fossils (trilobites, corals, brachiopods, sponges, arthropods, trace fossils, etc.) come from the Hunsrük Slates (Germany). In the terrestrial environment, primitive plants created the first soils, which sheltered such arthropods as myriapods, scorpions, and mites. The early Devonian plants still did not have true roots, but the rapid appearance of plant groups with roots occurred during the Late Devonian: lycophytes, sphenophytes, ferns, and progymnosperms. Rhynie chert Konservat-Lagerstätte (Scotland) includes significant well-preserved fossils of Devonian vascular plants. This rapid evolutionary radiation of plants has been called the Devonian explosion, and includes the first appearance of *Archaeopteris*. This is the first tree-like fern, and it can be found in worldwide outcrops. It was a genus of the extinct progymnosperms, plants with gymnosperm-like wood but that produce spores rather than seeds. The development of soils probably acted as a carbon dioxide sink, dropping the levels of greenhouse gases. This may have cooled the climate and caused the mass extinction event toward the end of the Devonian (the Frasnian-Famennian boundary event, 374 mya). The Late Devonian extinction was one of five major extinction events and affected about 82% of the species, including trilobites, ammonites, brachiopods, conodonts, and acritarchs. Ostracoderms and placoderms were extinguished. Meteorite impacts at the Frasnian-Famennian boundary have been suggested as possible agents for the Late Devonian mass extinction.

Carboniferous

The Carboniferous period (359–299 mya), subdivided into two subperiods (Mississippian and Pennsylvanian) in North America, is characterized by large expanses of soils, which remained successively buried, building up important coal deposits. Atmospheric oxygen levels probably increased, causing gigantism among Carboniferous insects and amphibians. The protodonata (griffin flies) are an extinct group related to dragonflies that reached a wingspan of more than 75 centimeters. The Mazon Creek Fossils (Illinois) Konservat-Lagerstätte contains well-preserved fossils of arthropods (insects, millipedes, spiders, scorpions, etc.) and of the other paleontological groups. Some labyrinthodont amphibians were longer than 6 meters, including the largest known amphibian, the 9-meter-long *Prinosuchus* of Brazil. The labyrinthodonts also include well-known amphibians like temnospondyl *Eryops* and anthracosaurian *Seymouria,* and they were accompanied by smaller lepospondyls. There is a controversy over the origin of lissamphibias, which include modern anuras (frogs and toads) and urodeles (newts and salamanders), although it is now considered that they evolved from lepospondyls. One of the greatest evolutionary innovations of the Carboniferous was amniote eggs among the earliest sauropsid reptiles. The earliest known reptiles are the theropsid *Archaeothyris* and the sauropsid *Hylonomus* from Middle Carboniferous sediments of Nova Scotia (Canada). Carboniferous terrestrial plants include an extensive diversity of equisetales (horsetails), sphenophyllales (vine-like plants), lycopodiales (club mosses), lepidodendrales (scale trees), filicales (ferns), pteridospermales (seed ferns), cordaitales, "pre"-cycadales, and volziales. *Lepidodendron* and *Sigillaria* evolved among the lepidodendrales, which are closely related to cycadales. *Calamites,* tree-like horsetails, is other significant genus of the Carboniferous period. An evolutionary event comparable with the appearance of eggs in the tetrapods was the evolution of seeds among the terrestrial plants (gymnosperms). This innovation occurred toward the end of the Devonian, but it was developed during the Carboniferous. It occurred in a primitive plant group called pteridosperms or seed ferns (e.g., *Lyginopteris*), which are considered to be the common ancestor of all gymnosperms (cycads, ginkgos, and conifers). *Cordaites* (a tree about 30 m high) is the most significant genus of cordaitales, a primitive and extinct group related to conifers. True conifers appear in the latest Carboniferous and belong to the voltziales, which are believed to be ancestral to living conifers (cedars, cypresses, junipers, pines, firs, redwoods or sequoias, spruces, and yews). In the oceans, ammonoids, brachiopods, foraminifera, corals, bryozoans, echinoderms (mainly crinoids), and chondrichtyes (sharks) flourished. The Bear Gulch Limestone (Montana) is an excellent outcrop

(Konservat-Lagerstätte) with well-preserved fossils of marine groups (sponges, starfish, conulariids, worms, brachipods, bryozoans, mollusks, as well as fishes such as lampreys, acanthodians, sharks, coelacanths, etc.). The fusulinids are very abundant in the Carboniferous fossil record. They are excellent index fossils for the Pennsylvanian and Permian shallow marine rocks, such as *Fusulina*. Brachiopods also were abundant and are excellent index fossils, including the well-known productids, spirifierids, rhynochonellids, and terebratulids. Bivalves and gastropods, echinoderms—mainly the crinoids like *Cyathocrinus*—were also very numerous. Among the cephalopods, the straight and curved-shelled nautiloids and the goniatitid ammonoids were common. Finally, fishes increased their diversity during the Carboniferous, becoming abundant: the elasmobranch chondrichtyes, that is, sharks such as *Psammodus* or *Symmorium*. From among the osteichtyans, palaeonisciformes and rhizodonts evolved. The first ones include the most primitive or earliest known actinopterygians (ray-finned fishes). The second ones are an extinct group of sarcopterygians (lobe-finned fishes). Freshwater fishes were common, such as the actinopterygian *Cheirodus* and the acanthodian *Acanthodes*. Hamilton Quarry (Kansas,) is an excellent outcrop (Konservat-Lagerstätte) with a diverse assemblage of Carboniferous marine, freshwater, and terrestrial fossils, including reptiles, amphibians, fishes, insects, conifers, echinoderms, and brachiopods.

Permian

The Permian period (299–251 mya) began with fauna and flora similar to the Carboniferous, but about the Middle Permian there was a major paleogeographic, paleoclimatic, and palaeobiologic turnover. All of the earth's major land masses were collected into a single super continent called Pangea, changing the ocean currents and causing deserts to increase. The dry conditions favored the gymnosperms, since the protective cover of the seeds represented a selective advantage with regard to the ferns and other pteridophytes that dispersed spores. The first modern gymnosperms—cycadophytes (cycads), ginkgophytes (ginkgos), and pinophytes (conifers)—appeared during the Permian. In the oceans, ammonoid and nautiloid cephalopods, echinoderms, brachiopods, and foraminiferal fusulinids were common. Permian marine sediments are rich in fossils of these groups, with ammonoid, brachiopod, and fusulinid being important Permian index fossils. Among the terrestrial fauna, insects and tetrapods (amphibians and reptiles) dominated. A number of important new insect groups appeared during the Permian, including the first coleoptera (beetles) and diptera (flies). Permian amphibians consisted of temnospondyls, lepospondyls, and batrachosaurs. They dominated the Early Permian terrestrial fauna together with reptilian pelycosaurs, being replaced by the therapsids (mammal-like reptiles) during the Middle and Late Permian. The therapsids evolved from a group of pelycosaurs, the sphenacodontids, and included the first large herbivores (anomodonts as *Eodicynodon*) and carnivores (theriodonts like gorgoniopsians and therocephalians). They also included the ancestors of mammals, the cynodonts, which probably appeared toward the end of the Permian. The other main group of reptiles, the sauropsids, was represented by anapsids such as millerettids, nyctiphurets, pareiasaurs, and procolophonids. The latter survived into the Triassic and probably include the ancestor of the testudines (turtles). In the marine environment, gastropods, bivalves, echinoderms, brachiopods, ammonites, and fusulinid foraminifers were very abundant. These two last groups contain the most significant Permian index fossils. The Permian

Allosaurus was a powerful predator that walked on two powerful legs, had a strong, S-shaped neck, and had vertebrae that were different from those of other dinosaurs (hence its name, the "different lizard"). It was up to 38 feet long (12 m) and 16.5 feet tall (5 m).

Source: Bob Ainsworth/Morguefile.

ended with the most extensive mass extinction event recorded in the earth's history: the Permian-Triassic (P-T) boundary event. It has been estimated that more than 95% of marine species and 70% of land vertebrate species became extinct. Although the cause of the Permian mass extinction is under debate, a multiple scenario including glaciations, volcanic eruptions, and meteoritic impacts is broadly accepted.

Mesozoic Fossil Record: From the P-T Extinction Event to the K-T Extinction Event

Triassic

The P-T mass extinction event marks the Paleozoic-Mesozoic boundary, with the Triassic (251–199 mya) being the first period of the Mesozoic. The Triassic climate was generally hot and dry and therefore suitable for gymnosperm trees and reptiles. Triassic land plants include forms that survived the P-T event, including vascular plants both without seeds (lycophytes, cycads) and with seeds (glossopterid pteridospermatophytes, ginkgophytes, and conifers). The conifers flourished during the Triassic period, mainly in the northern hemisphere (the Petrified Forest in Sonoma County, California, is the most significant fossil record of Triassic conifers, consisting mostly of extinct *Araucarioxylon*). Although the archosaur reptiles first appeared toward the very end of the Permian, they evolved into more advanced types during the Triassic, including crurotarsans, phytosaurs, aetosaurs, and rausichids. In addition, the first crocodylians (*Saltoposuchus*), pterosaurs (*Scleromochlus*), and dinosaurs (*Marasuchus, Lagerpeton*) appeared in the Middle and Late Triassic. Amphibians such as temnospondyls and lissamphibians, the earliest turtles (*Proganochelys, Proterochersis*), and lepidosauromorphs (similar to tuataras) complete the land fauna. In marine environments, the ammonites diversified from a few survivors of the P-T event. The previous goniatitids and ceratitids were replaced by true ammonitids, the evolved Phylloceratina. In addition to ammonites and fishes, the marine fauna were characterized by such marine reptiles as pachypleurosaurs, nothosaurs, placodonts, plesiosaurs, and ichthyosaurs. Finally, new modern groups of corals, the scleractinians, appeared in the Early Triassic. One of the best Triassic outcrops is the 237-million-year-old Monte San Giorgio Konservat-Lagerstätte (Lake Lugano region, northern Italy and Switzerland), where abundant well-preserved fossils of fishes and marine and terrestrial reptiles are recorded. Other Triassic Konservat-Lagerstätten are Ghost Ranch (New Mexico) and Karatau (Kazakhstan). The Triassic ended with one of the five major mass extinctions of the Phanerozoic: the Late Triassic extinction event, which affected 70% of species, including sponges, ammonites, conodonts, brachiopods, insects, and many vertebrate groups (archosaurs, dicynodonts, and cynodonts). The latest Triassic extinction event was probably a cluster of smaller events, with at least two of them standing out: the 208-million-year-old Norian event and the 199-million-year-old Triassic-Jurassic boundary event. The origin of these finitriassic extinctions is poorly known, but such extinctions allowed the dinosaurs to expand into many niches that had become vacant.

Jurassic

The Jurassic period (199–145 mya), together with the subsequent Cretaceous period, is known as the Age of Dinosaurs. It was the golden age of the great herbivorous sauropods, for example, *Diplodocus, Brachiosaurus, Apatosaurus,* or the giant *Supersaurus* (40–45 m in length, 50–60 tons), and carnivorous theropods like *Ceratosaurus, Megalosaurus,* and *Allosaurus*. The first birds evolved from small coelurosaur theropods, with the famous Jurassic *Archaeopteryx* being the earliest and most primitive known bird. Solnhofen Limestone (Germany) is a Jurassic Konservat-Lagerstätte that includes excellent preserved fossils of *Archaeopteryx*. Both sauropods and theropods are saurischian dinosaurs and were more abundant than the other major group of dinosaurs, the ornithischians. Nevertheless, this latter dinosaur group also played an important role in the land environment as small herbivorous, the stegosaurids as *Stegosaurus,* and nodosaurids like *Panoplosaurus*. Other significant Jurassic reptiles were the pterosaurs. The warm, humid climate that characterized the Jurassic period allowed much of the landscape to be covered by lush jungles dominated by conifers (e.g., extinct Cheirolepidiaceae or extant Araucariaceae and Pinaceae). Bennettitales, cycads, ginkgos, and tree ferns were also common. The bennettitales are curious extinct cycad-like plants that had hermaphrodite strobili with ovulate and staminate sporangia in a flower-like arrangement. This plant group has been connected to angiosperms (true flowering plants), although the relationship is under debate. In the sea, ammonites, belemnites, fishes, and marine reptiles, including ichthyosaurs, plesiosaurs, and crocodiles, were the predominant fauna. Holzmaden Konservat-Lagerstätte (Germany) includes well-preserved Jurassic fossils of ichthyosaurs and plesiosaurs as well as ammonites. The rudists, a group of bivalves, formed reefs in the shallow seas of the Cretaceous. Well-preserved fossils of coeloid cephalopod (octopus and vampire squids) are found in the Konservat-Lagerstätte of La Voulte-sur-Rhône (France). In the protista world, new groups appeared, like the evolved planktonic foraminifera and calpionelids. Both are planktonic groups and are good Jurassic index fossils.

Cretaceous

The Cretaceous period (145–65 mya) was very warm and humid worldwide, allowing fossils of warmth-adapted plants and dinosaurs to be found at outcrops as far north as Alaska and Greenland and as far south as 15 degrees from the South Pole. Conifers continued being predominant in the flora, but angiosperms (flowering plants) spread during this period (e.g., magnolias) whereas bennettitales died out before the end of the Cretaceous. *Archaefructus,* found in the Yixian Formations (China), has been proposed as one of the earliest known angiosperms. The land fauna was dominated by dinosaurs, which were at their most diverse. Some of them are popularly known such as *Tyrannosaurus, Apatosaurus* (= *Brontosaurus*), *Triceratops, Iguanodon,* and *Ankylosaurus or Velociraptor.* Some reached giant size, like the sauropod *Argentinosaurus* (30–35 m in length, 90 to 110 tons) and *Bruhathkayosaurus* (40–45 m in length, 175 to 220 tons). *Maniraptora* include transitional forms between dinosaurs and birds, whereas mammals were small and still a minor component of the land fauna. The best fossil record of dinosaurs are found in well-preserved outcrops (Konservat-Lagerstätte) of Auca Mahuevo (Patagonia, Argentina), the Río Limay Formation (Neuquén, Argentina), the Santana Formation (Brazil), and the Yixian and Chaomidianzi formations (Liaoning, China). The Xiagou Formation (Gansu, China) is a Konservat-Lagerstätte with well-preserved fossils of *Gansus,* the earliest true modern bird. Insects began to diversify in a coevolutionary process with flowering plants, with new insect groups like Hymenoptera (ants), Isoptera (termites), Lepidoptera (butterflies), and Orthoptera (grasshoppers) now appearing. The Konservat-Lagerstätte of the Zaza Formation (Baissa, Siberia) contains numerous exceptionally well-preserved insects. Ammonites, globotruncanid planktic foraminifera, ichthyosaurs, plesiosaurs, mosasaurs, rays, sharks, and modern teleost fishes dominated the oceans. A radiation of diatoms, a significant phytoplanktonic group of protist algae with siliceous shells, occurred during the Cretaceous. Planktic foraminifers and ammonites are the best index fossils of the Cretaceous. The Cretaceous period ended with one of the major mass extinction events, caused by the impact of a meteorite 10 kilometers in diameter. Dinosaurs, pterosaurs, ammonites, belemnites, marine reptiles, rudist bivalves, and globotruncanid foraminifers become completely extinct. More than 75% of species were affected by the K-T extinction event.

Cenozoic Fossil Record: From the K-T Extinction Event to the Present

Paleogene

The Paleogene period (65–23 mya) is subdivided into three epochs: Paleocene (65–56 mya), Eocene (56–34 mya), and Oligocene (34–23 mya), and is notable for being the time during which mammals evolved from small insectivores that survived the Cretaceous-Tertiary event and diversified into large forms that dominated the land. Paleocene mammals included monotremes, marsupials, multituberculates, and primitive placentals (mesonychids). Birds also began to diversify during the Paleocene, including large carnivorous birds like *Gastornis.* Flowering plants continued to develop and proliferate, coevolving with the insects. In the oceans, sharks became the top predators after the K-T extinction of the marine reptiles. The Eocene epochs started with one of the most rapid and extreme global warming events recorded in geologic history (the Paleocene-Eocene boundary event), causing an extinction event in the deep ocean environment (benthic foraminifera) but significant radiation in the shallow seas and land fauna and flora. Fossils of subtropical–tropical trees have been found even in Alaska and Greenland. Modern mammals, like artiodactyls, perissodactyls, proboscidians, bats, and primates, appeared during the Eocene. Significant Eocene Konservat-Lagerstätte come from London Clay (England), Monte Bolca (Italy), Messel Oli Shale (Germany), and the Green River Formation (Colorado, Utah, and Wyoming). A gradual extinction event triggered by severe climatic and vegetational changes occurred across the Eocene-Oligocene transition. At this time, the world experienced a global cooling that caused the formation of the Antarctic ice cap and rearranged many of the existing biomes. Tropical areas, such as jungles and rainforests, were replaced by more temperate savannahs and grasslands. The Late Eocene event drastically affected land mammals (the *Grande Coupure*), including the extinction of mesonychids. Oligocene mammal assemblages include the well-known perissodactyl *Brontotherium,* rhinocerotid *Indricotherium,* creodont *Hyaenodon* or equid *Mesohippus,* among others. In the seas, the cetaceans (whales) had just evolved from their ancestors, the archaeocetids, which had first appeared during the Eocene, evolving from artiodactyls (perhaps from hippopotamids). Riverleigh (Queensland, Australia) is a significant Oligocene-Miocene Konservat-Lagerstätte containing ancient marsupials (*Thylacinus,* a Tasmanian tiger; *Silvabestius,* a giant wombat; *Ekaldeta,* a carnivorous rat kangaroo; *Nimiokoala,* an ancient koala, etc.).

Neogene

The Neogene period (23–0 mya) is subdivided in four epochs: Miocene (23–5.3 mya), Pliocene (5.3–1.8 mya), Pleistocene (1.8–0.01 mya), and Holocene (the past 10,000 years). It is a unit of geologic time during which birds and mammal evolved considerably, culminating with the appearance of the genus *Homo*. Due to a generally cooler and drier climate during the Miocene, grasslands underwent a major expansion at the expense of forests. Miocene mammals and birds, as well as other continental and marine fauna were fairly modern. Significant Konservat-Lagerstätte-type outcrops of the Miocene epoch come from 15- to 20-million-year-old Clarkia Fossil Beds (Idaho) and 10-million-year-old Ashfall Fossil Beds (Nebraska). The Pliocene climate became still cooler and drier than that of the Miocene, forming the Arctic ice cap; reducing tropical plants worldwide; spreading deciduous forests, coniferous forests, grasslands, and tundra; creating deserts in Asia and Africa; and evolving essentially modern fauna (mastodonts, elephants, rhinos, giraffes, tapirs, saber-toothed tigers or smilodons, dogs, hyenas, horses, cows, antelopes, etc.). The primates continued their evolution, appearing as *Australopithecus* in the late Pliocene (more than 4 mya). The cooling of the climate culminated in the Pleistocene, an epoch characterized by repeated glacial cycles. A significant Pleistocene Konservat-Lagerstätte is found in the 20,000-year-old La Brea Tar Pits (Los Angeles, California), a tar pit that trapped numerous animals and plants, including ancient bison, American camels, coyotes, jaguars, mammoths, American mastodons, and even humans. The genus *Homo* first appeared during the Pliocene-Pleistocene transition, with *H. habilis* and *H. rudolfensis* being their first representatives. Other *Homo* species evolved progressively across the Pleistocene, such as *H. ergaster, H. erectus, H. antecessor, H. heildenbergensis, H. neanderthalensis, H. rhodesiensis,* and finally *H. sapiens*. The best outcrops of *Australopithecus* and *Homo* come from Hadar (Ethiopia), Olduvai Gorge (Tanzania), Lake Turkana (Kenya), Kimberley (South Africa), Solo River (Java), Zhoukoudian (China), Atapuerca (Spain), Mauer (Germany), La Chapelle-aux-Saint (France), and Shanidar (Iraq).

The beginning of the Holocene corresponds with a period of warming (Holocene climatic optimum) after of the last ice age, and with the development of human cultures. Humans have evolved into a significant agent of extinction. Deforestation, agricultural practices, pollution, overhunting, and numerous other human activities are causing the so-called Holocene extinction event, including numerous species of plants, mammals, birds, amphibians, reptiles, and arthropods. It is also beginning to be called the sixth extinction, since it may become as important as the five major extinction events of the Phanerozoic: the Late Ordovician, Late Devonian, P-T boundary, Late Triassic, and K-T boundary mass extinction events.

Fossils, Interpretations of

Fossils, the remains of once-living organisms or their behavior, have long been known to humankind, but interpreted differently depending on time and place. Since their first recorded discovery by ancient Greeks, Romans, and Native Americans, fossils have been explained as the remains of gods and giants, used to support notions of natural magic, treated as petrified organisms killed in Noah's Flood, and ultimately regarded as some of the strongest evidence for Darwinian evolution. The scientific study of fossils began in the 16th century and has changed dramatically, depending on the prevailing views of the scientific community and the technology available to researchers. Today, the science of paleontology is a vibrant discipline strongly integrated with geology, biology, chemistry, and other sciences.

Although fossils were discovered and often interpreted by the ancient Greeks, Romans, and Native Americans, the first rigorous and systematic studies of fossils were carried out by 16th-century European naturalists. To these naturalists, the word *fossil* referred to a range of natural curiosities dug from the earth, including stones, gems, and the remains of once-living organisms that comprise today's concept of fossils. Early naturalists, however, had a difficult time recognizing the organic nature of fossils, due both to philosophical constraints and to the very practical difficulty of identifying often fragmentary and eroded specimens. Several encyclopedic works, including Georg Bauer's (1494–1555) *On the Nature of Fossils* and Conrad Gesner's (1516–1565) *On Fossil Objects,* recognized the extraordinary similarity between some fossils and living organisms, but were hesitant to describe these specimens as the remains of once-living creatures. Instead, many naturalists of the time considered fossils to be the result of natural magic or a "plastic force" that could reproduce the shapes of common objects in situ in solid rock. These views were tied into an overarching natural philosophy that saw the world as a harmonious and interlocking web of affinities, guided by supernatural powers.

Although often hinted at by philosophers (including Xenophanes of Colophon and Leonardo da Vinci), the organic nature of fossils was first rigorously demonstrated by Nicolaus Steno (1638–1687), a Danish anatomist and crystallographer. In dissecting the head of a giant shark that washed up near Livorno, Steno noticed an uncanny resemblance between the creature's teeth and glossopetrae, a type of odd stone common on Malta that was thought to have curative and magical powers. While others had previously noted the resemblance, they were at a loss to explain how petrified sharks' teeth were found on land, often on mountains thousands of feet above sea level. Noting that glossopetrae resembled a modern shark tooth in every respect, Steno wrote that these stones must be the remains of once-living organisms, a conclusion he generalized to other fossils that resembled living creatures or their organs, such as bones, shells, and leaves. This conclusion was strongly supported by early microscopist Robert Hooke (1635–1703), who used this new instrument to examine the microscopic composition of fossils, which he found to be nearly identical to the microstructure of the living organisms they resembled.

With the organic nature of fossils now secure, most researchers at the time regarded fossils and their entombing rocks as products of Noah's Flood. However, based on field excursions in Tuscany, Steno recognized that rocks are found in layers made of different materials, which he hypothesized as representing a sequence of different events in the history of the earth. The notion of sequential periods in earth history was supported by noted French anatomist Georges Cuvier (1769–1832), whose careful comparisons of fossil sloth and elephant specimens to their modern counterparts recognized the former as distinct species. By now, exploration of the New World made it implausible that these fossil species would be found alive in an unexplored corner of the globe, indicating to Cuvier that they must have gone extinct. Up until this point, early naturalists such as Martin Lister (c. 1638–1712) and John Ray (1627–1705) regarded extinction as impossible, as it would imply imperfection in God's creation. To Cuvier, the reality of extinction suggested that earth history could be divided into distinct periods punctuated by "revolutions," an idea that soon found support in the geological fieldwork of Jean-André De Luc (1727–1817). Furthermore, Cuvier himself carefully studied the thick rock sequences exposed in the gypsum quarries at Montmartre, and found evidence of several very different faunas of fossil mammals, which gradually became increasingly differentiated from modern faunas further back in time. Additional exploration, especially in Great Britain, revealed several distinct periods in geological history, including an era dominated by reptiles (dinosaurs, plesiosaurs, ichthyosaurs, etc.).

Cuvier roundly denied the possibility of evolution, but his research and that of others conclusively demonstrated that new species must have arisen over time to explain the distinct new faunas appearing after his "revolutions." At the same time, James Hutton (1726–1797) and Charles Lyell (1797–1875) provided decisive evidence that the Earth was ancient, not several thousand years old as theorized by Biblical scholars. Although most of his argument focused on living species and selective breeding, Charles Darwin (1809–1882) used evidence of distinctive faunas and an ancient Earth to argue for the reality of evolution by natural selection. Two years after the publication of Darwin's *On the Origin of Species* (1859), the discovery of the Jurassic bird *Archaeopteryx* in Germany provided the first convincing "missing link," as its combination of reptilian (teeth and a long tail) and avian (feathers and wings) features indicated an evolutionary transition between these two groups. In the following decades, a nearly complete assemblage of horse fossils from the newly opened American West was used by Thomas Henry Huxley (1825–1895) and O. C. Marsh (1831–1899) to illustrate gradual progressive evolution over time. Additional discoveries by Marsh, including several toothed Cretaceous birds, revealed the early evolutionary history of living animal groups. From the time of Darwin, Huxley, and Marsh to the present day, fossils have been interpreted in an exclusively evolutionary context, and continue to help scientists understand the patterns and processes of evolution. The recent hypothesis of punctuated equilibrium, which postulates that longtime evolutionary stasis is punctuated by rapid speciation, was supported with careful study of extensive trilobite fossil faunas from the eastern United States.

Today, the science of paleontology is a dynamic and vibrant discipline that is becoming increasingly integrated with other fields of research. The discovery, preparation, and study of fossils are constantly changing with the development of new technology, such as molecular DNA analysis and CT scanning. The philosophical framework of paleontology has changed as well, and cladistic methodology is routinely used to study the genealogical relationships of organisms, and sophisticated statistical techniques are used to examine patterns of evolution. As is evident from its history, paleontology will continue to change over time with the development of new research methods, new technology, and new scientific philosophy.

Fossils, Living

Evolution is not a constant but rather an unpredictable process. Some organisms undergo multiple and significant physical alterations over a span of a few centuries. Others endure millions of years with little change, leaving their present-day form almost a mirror image of a distant ancestor; these latter life forms are commonly referred to as "living fossils" and are unique residuals of time.

Enduring Organisms

Coelacanth

The present-day coelacanth, *Latimeria chalumnae,* is believed to be a fish from which the first amphibians may have evolved approximately 400 million years ago (mya). The discovery of a living specimen during the mid-20th century caught scientists unaware since such fish were thought to be extinct. Through subsequent investigations, the *Latimeria chalumnae,* which resembles coelacanths from 100 mya, was determined to live off the Comoro Islands at depths of more than 500 feet. Ichthyologists believe that limited competition and a lack of natural predators provided *Latimeria chalumnae* with a stable environment in which to survive relatively unchanged. Whatever circumstances made it possible for a coelacanth species to survive, and no matter the distinctive differences between *Latimeria chalumnae* and its predecessors, there is no question of the coelacanth's status as a living fossil.

Coniferous Trees

Vast grasslands covered much of North America when Native Americans first explored the continent over 12,000 years ago. Even then, coniferous trees, including pine and spruce variants, existed; a great span of time in terms of humanity's antiquity, but a mere instant in the life of conifers.

Coniferous trees surfaced toward the end of the Paleozoic era, over 200 mya. A plant variety we consider so ordinary today, using pine and spruce for lawn decoration and even holiday fixtures, has an antiquity rivaling dinosaurs, making conifers living fossils hidden in plain sight.

Dragonflies

A multitude of dragonfly species exist today, all of which possess bodies that are as lethal as they are elegant. Dragonflies are predators, subsisting on a diet of mosquitoes, midges, and other small insects. Two sets of strong wings enable them to hover and then accelerate rapidly. Remarkably, these persistent insect-hunters are continuing on an evolutionary trek encompassing more than 300 million years. As for contemporary species, they started surfacing roughly 100 mya. A recognizable form of that antiquity certainly qualifies the dragonfly as a living fossil.

Ferns

Fern species are as diverse as they are ancient, the variety of fern designs seemingly endless. Yet, such diversity does not mean that modern ferns do not bear any significant resemblance to older forms. In fact, the complex designs of modern ferns mirror those of ferns that appeared approximately 300 mya. Then, as now, ferns endured changing climates and survived while other plant and animal species disappeared. This endurance of fern species, as potent now as it was millions of years ago, is what earned ferns the title of living fossils.

Goblin Sharks

The infamy of *Carcharodon carcharias* (great white shark) continues to capture the attention of researchers and beach enthusiasts alike. Consequently, our understanding of *Carcharodon carcharias* has increased dramatically to include a clearer knowledge of its earliest (modern) ancestors, which emerged approximately 60 mya. Yet, with even so lengthy a history, *Carcharodon carcharias* is far from being an elder among shark species. Today, a number of sharks reflect nearly 100 million years of relative stasis, earning them the title of living fossil. Of these, *Mitsukurina owstoni* (the goblin shark) is arguably the most unique.

With a flat, extended snout positioned above its mouth, resembling a horn or similar projection, *Mitsukurina owstoni* is an oddity. With specimens first being acquired and described at the end of the 19th century, *Mitsukurina owstoni*'s similarity to ancient sharks (long believed extinct) quickly became apparent. *Mitsukurina owstoni*'s ancestry was ultimately traced to the Cretaceous period, extending the terrestrial presence of similar species to over 100 million years.

Horseshoe Crabs

The armored body of the horseshoe crab, *Limulus polyphemus,* is hard and nearly impenetrable. After an examination of the fossil record, it is also apparent that the horseshoe crab's design is long-lived.

Horseshoe crabs appear ancient, complete with an armor-plate-covered body reminiscent of several dinosaur species. Yet, given the design of horseshoe crabs, it is astonishing how resilient these creatures are. Although very resilient, horseshoe crabs do suffer continual fluctuations in their environment, enduring varying moisture and salinity levels and even high levels of pollutants. The casual observer of these creatures will undoubtedly be astounded by the reality of horseshoe crab hardiness. Yet, when looking at the fossil record, the durability of these creatures becomes understandable.

The current species of horseshoe crabs are quite similar to ancestors living 300 mya. For such a biological design to endure that long, horseshoe crabs must be engineered well, considering the dramatic changes the planet continues to undergo.

Future Living Fossils

Archaeologists and paleontologists use picks, shovels, and trowels to uncover the past and reveal fossils of species that once inhabited the planet. Living fossils, such as the species aforementioned, provide a similar glimpse into the past, and in the process make the remote past seem more tangible, more real. It is inviting to speculate which of the species that are common today will become the living fossils of the distant future.

Fossils and Artifacts

Individually, artifacts and fossils offer archaeologists, historians, and paleontologists glimpses of the past, with artifacts reflecting technological developments and fossils indicating life forms that once inhabited a biome. When examined together, artifacts and associated fossils, in both primary and secondary contexts, provide additional insight into an archaeological site's formation processes and, ultimately, an idea as to a site's and its affiliated life forms' place in time.

Occupation of North America

It was in 1927 that excavators first discovered Paleoindian projectile points near Folsom, New Mexico, a discovery with immediate and substantial ramifications. Before 1927, scholars thought that Native Americans had traversed North America only a few thousand years earlier. The projectile points, often fluted, which are now referred to as "Folsom" points, were found associated with the fossilized remains of an extinct species of bison, suggesting Native American occupancy more than 5 thousand years earlier than previous believed. What made the discovery even more convincing was that Folsom points were found embedded in some of the remains. Today, we have radio-carbon dating to verify the Folsom discoveries. In 1927, the excavators relied on the simple collaboration of artifacts and fossils to understand the site's temporal implications, a method far from absolute, but effective nonetheless.

The Emergence of Tool Traditions

The Sterkfontein site, a collective of cavern remnants located in South Africa, continues to yield fossil remains of early hominid species and a variety of early lithic tools, including *Australopithecine* and *Homo habilis* specimens for the former and hand axes for the latter. The overlapping of specimens at Sterkfontein contributes to ongoing debates on when and by whom Oldowon and later tool traditions were created. With Sterkfontein hominid remains estimated at over 1.5 million years old and the associated tools resembling Acheulean traditions, which would be an early Acheulean discovery, it is clear that hominids had created stone tools nearly 2 million years before the present (BP); an understanding gained through an analysis of artifacts and associated hominid fossils.

Environmental Change and Technological Innovation

The understanding of plant domestication, particularly in the Near and Middle Eastern regions where initial domestication efforts took place, remains a strong research objective of paleoanthropologists and paleontologists alike. Consequently, an endless collection of artifacts and fossilized pollen grains has been gathered and partially analyzed, providing clues as to the process by which humanity learned to manage plants for consumption purposes. A consequence of this research is knowledge of paleoenvironments and the technological adaptations made by human populations responding to environmental changes through time. As with previous associations of artifacts and fossils, but with fossilized plants instead of fossilized animal remains, the examination of assemblages provides greater insight than natural or manufactured collections alone, ultimately providing a better understanding of humanity through time.

Frankenstein, Legend of

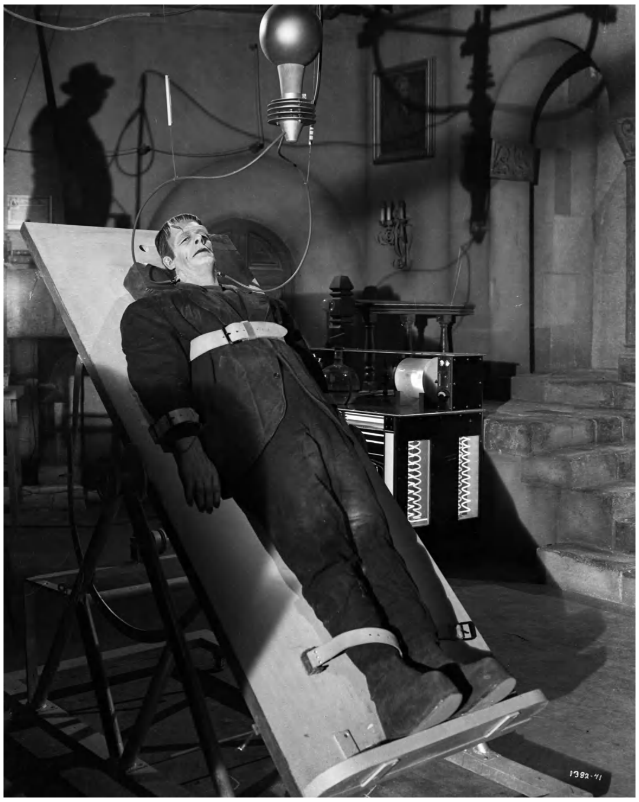
Frankenstein, or The Modern Prometheus, was composed in the summer of 1816 by the 19-year-old Mary Wollstonecraft, later the wife of poet Percy Bysshe Shelley, during a vacation she spent on the shores of Lake Geneva with Shelley and their friend the poet George Gordon, Lord Byron. The weather was cold and rainy; to pass the time, she, Shelley, and Byron engaged in a contest to craft the best horror story. Published anonymously in 1818, Mary Shelley's gothic novel has continued to exert an influence on literature and popular culture for nearly 200 years. The theme of man's overreaching in an effort to take on godlike powers and create an immortal life form has resonated deeply in the popular imagination as a warning against scientific hubris and the consequences of tampering with the forces of nature. It has been credited with giving rise to the horror genre, with variants of the Frankenstein story portrayed in dozens if not hundreds of stage and film adaptations. Although most such adaptations have been based only very loosely on the novel, the hideousness of the monster's appearance and the rejection that this disfigurement creates has remained a constant element.

In the novel, Victor Frankenstein, a young medical student, studies biology and chemistry at the University of Ingolstadt in Switzerland. He becomes obsessed with creation, and in following the scientific advances of his professors, he experiments with reanimation to bring dead tissue back to life. During his studies, Victor Frankenstein takes up a reclusive existence. He abandons and rejects family and friends as his work takes him from clandestine experiments in his makeshift laboratory to committing acts of grave robbery to gather the raw materials from which he hopes to create a new life form that could live indefinitely. When his offspring awakens, we witness not a scientist jubilant in success but a man horrified by his actions, shocked by the monstrosity of his work. Victor Frankenstein abandons the life he has created and shuns and rejects his creation.

The monster, now frightened and isolated, begins to experience feelings and sensations just as any small child would, but unlike an infant or child who has a parent or guardian to guide him, the creature is alone. He realizes this, and in learning to exist in exile, mistreated and rejected by villagers, his heart hardens and he swears revenge. When monster and creator are reunited, the monster articulately defines the sins of his father. The monster says that he was born good and benevolent, but that misery and rejection have turned him into a fiend. He then curses Frankenstein and demands a companion. In exchange, the monster promises to go into hiding with his mate forever.

The novel achieved almost immediate notoriety; within just 5 years of its publication several theatrical versions emerged, gaining wide attention across Europe. The first theater performance was a three-act play, *Presumptions; or The Fate of Frankenstein,* by Richard Brinsley Peake. Many changes were made in this adaptation, including the addition of a clumsy and comedic laboratory assistant who became a stock figure in subsequent versions of the story. In this version, he is named Fritz and Victor is called "Dr. Frankenstein." In addition, in this and later adaptations, the monster is unable to speak or to learn, unlike the creature in Mary Shelley's original.

Over time, the Frankenstein monster evolved into a popular cultural icon through many stage and film adaptations of the tale. The first Frankenstein film was Thomas Edison's 16-minute film, *Frankenstein* (1910). The German version, *Golem,* was released in 1914. In 1931 Universal Studios released James Whale's *Frankenstein* into mainstream popular culture. The actor Boris Karloff portrayed Shelley's articulate, educated, and sensitive creature as a mute and maniacal beast without soul or conscience. For 2 decades Universal Studios produced a series of Frankenstein movies, including



Bela Lugosi (1882–1956) takes his turn as Frankenstein's monster in Frankenstein Meets the Wolf Man, *directed by Roy William Neill.*

Source: Getty Images.

The Bride of Frankenstein (1935), *The Son of Frankenstein* (1939), *Ghost of Frankenstein* (1942), *Frankenstein Meets the Wolf Man* (1943), and *House of Frankenstein* (1948). In each film, a stitched forehead, lumbering lanky limbs, and sunken eyes branded the monster's appearance. Electrodes jutted from each side of his neck to complete the iconic monster mask. Mary Shelley's original intent to portray the creature as a lost soul, abandoned and scorned, was jettisoned in favor of inciting fear and revulsion in the audience.

In 1957, Hammer Films produced *The Curse of Frankenstein* with Peter Cushing as Victor Frankenstein and Christopher Lee as the monster. It is in this film that we see the first reference to Frankenstein's well-known "mistake" of using a defective brain in the creation of the monster, thus providing a rationale for the monster's violent nature.

The 1994 film *Mary Shelley's Frankenstein,* directed by Francis Ford Coppola and starring Kenneth Branagh, Robert DeNiro, and Helena Bonham Carter, was the first cinematic version to attempt to maintain fidelity to the story as Mary Shelley had written it, allowing audiences to see and understand Victor Frankenstein and his creature as the author had intended.

Frege, Gottlob (1848–1925)

Gottlob Frege was a German mathematician and logician as well as a philosopher. He is considered the major founder of modern logic. His uniquely profound research led him from pure mathematics, like the methodizing of natural numbers or "the proof," to a highly philosophical approach to mathematical logic and the foundation of mathematics, and even to consequential findings in the field of linguistics. Applicable to most fields of logic, Frege's research exerted an influence far beyond pure mathematical logic. He is considered to have advanced logic beyond Aristotle, despite the fact that he failed in constructing a consistent axiomatic foundation for logic. Consequently, Frege holds a significant place in the historical development of logic and mathematics from ancient Greece to our modern times.

Life and Work

F. L. Gottlob Frege was born on November 8, 1848, in Wismar, northern Germany, in the state of Mecklenburg. He was the son of Alexander Frege, the principal of a private high school in Wismar. It is probable that the influence of his teacher at the local gymnasium, Leo Sachse, motivated Frege to study after school. Subsequently he enrolled as a student in mathematics, chemistry, physics, and philosophy; first from 1869 to 1871 at the University of Jena under the encouragement of the famous physicists Ernst Abbe and Karl Snell; next he expanded his studies for 2 more years at Göttingen University, where he eventually obtained a doctoral degree in 1873 with the valued geometrical thesis translated as *On a Geometrical Representation of Imaginary Figures in a Plane.* Just one year later, Frege received his second doctorate (habilitation) for his work *Methods of Calculation Based Upon an Amplification of the Concept of Magnitude,* comprehending some initial steps of his theory of higher (complex) mathematical functions.

Also in the year 1874, upon recommendation of his academic teacher Abbe, Frege became a lecturer in mathematics at the University of Jena, where he would remain all his professional life. He taught extensively in all mathematical disciplines. His research, however, concentrated on the philosophy of logic. Persistent dialogue—noteworthy because Frege was extremely reserved in general—with his Jena colleague and one of his few friends Rudolf Eucken, later a winner of the Nobel Prize in literature, supported Frege's philosophically mathematic thinking.

In 1879, Frege's seminal first work *Concept Script, a Formal Language of Pure Thought Modelled Upon That of Arithmetic* (*Begriffsschrift*) was published. He developed a principle for the construction of a logical language. In the aftermath of the *Begriffsschrift,* Frege was made associate professor at Jena University. Frege married Margarete Lieseberg, but unfortunately neither of their two children survived into adulthood, so they adopted a boy named Alfred.

Frege's book *The Foundations of Arithmetic* (*Grundlagen*) appeared in 1884. It comprised for the first time a complete system for the foundation of arithmetic based on a set of mathematically logical axioms. To gain higher recognition for his work, this book was written in completely nontechnical, natural language.

In conjunction with his profound research into the logical system of mathematics, Frege felt impelled to develop a philosophy of language. His major work on a linguistic system supporting the philosophy of logic is *On Sense and Reference* (1892). In this book, Frege's two famous linguistic puzzles were presented, distinguishing between sense and the denotation of terms in order to resolve the ambiguities of language.

In 1893, with the first volume of *Basic Laws of Arithmetic* (*Grundgesetze*), Frege's major opus on the philosophy of mathematics was published. Frege used to say that "every good mathematician is at least half a philosopher, and every good philosopher is at least half a mathematician." Because almost no colleague of his in the world was able to understand what Frege had managed to find, none of his publications achieved immediate success, and he even received some very poor reviews.

Nonetheless, Frege was promoted to honorary professor in Jena in 1896, giving him a regular income for the first time in his life. Years of bad luck followed. In 1902, Frege received a letter from Bertrand Russell who modestly pointed out that he had discovered a paradox caused by a severe inconsistency in Frege's set of logical axioms. Also, the second volume of the *Basic Laws* was based on the misarranged axioms but was already finished and was (at that exact time) with the printer. Unfortunately, even the amendment to his axiomatic system that Frege added as an appendix proved to be inconsistent; as some say, Frege must have known this but was unable to accept his failure. Frege gave up writing the intended third volume of the *Basic Laws* and never again published any research. His late attempt to base logic on geometry instead of arithmetic could not be elaborated any further.

During the First World War, Frege retired and after the death of his wife he left Jena; he lived in increasing reclusiveness and died on July 26, 1925, in Bad Kleinen, Germany.

Influence

Frege left deep traces in two fields of philosophical research: in the logic of mathematics and in the philosophy of language. In the first, he marks the beginning of modern science. His invention of quantified variables (predicate calculus) to replace the ambiguous meaning of natural language not suitable for the denotation of complex mathematical terms was seminal to the development of mathematics. His influence arises not only from separate theorems Frege published himself, but also is founded on the diffusion of his very elementary logic and philosophical findings into countless studies.

Frege's analytical philosophy is connected with Locke's and Hume's empiricism. In a far-reaching empiricist manner and as a central point in his logic, which is founded on the sole relevance of the logical truth of an argument, Frege did not accept any nonfalsifiable fact or instance; hence he was in deep doubt about transcendental phenomena, and epochs do not seem to have attracted his attention.

Personality

For a man in determined pursuit of new scientific findings, Frege was extremely conservative in his political attitude. Especially in his later years, the embittered Frege was an enthusiastic monarchist, anti-democrat, anti-French, anti-Catholic, and anti-Semite.

Frege displayed signs of immoderate self-regard and refused to accept or even to consider the criticism of his colleagues. To the contrary, he reacted with embitterment and polemic attacks on his critics, which seems an inadequate response in light of Frege's undoubtedly immense and lasting scientific achievements in the fields of logic and the philosophy of mathematics and language.

Futurology

Futurology is an interdisciplinary field that analyzes past and current conditions, events, and trends for the purpose of forecasting future developments. Alternate terms include *future studies, futuristics, forecasting,* and *futurism.* During this time of rapid technological, scientific, and social change, futurology is more important than ever. However, the goal of futurology is not to predict specific events or one-time occurrences, but to improve our probable or alternative futures.

Futurology is a relatively new field of study, first espoused by science fiction author H. G. Wells, who called for the establishment of "Departments and Professors of Foresight" during a 1932 BBC broadcast. The term *futurology* was first used during World War II by political scientist Ossip Flechteim, to describe this new field of knowledge based on a probable and systematic analysis for the future. During the Cold War, Herman Kahn, Olaf Helmer, and other experts at the RAND Corporation think tank laid the methodological foundations for futurology by employing the scenario technique, game theory, and systems analysis to analyze military strategy.

With these foundations set, it was possible to conduct the first course devoted to futurology, taught by Alvin Toffler at The New School for Social Research in New York in 1966. Most of Toffler's key ideas are encapsulated in his book *Future Shock,* about the effects of accelerated rates of change on society, including "super-industrialization" and "information overload." Toffler named some well-known and influential futurists of his time in his 1972 edition of *The Futurists,* such as R. Buckminster Fuller, Marshall McLuhan, and Margaret Mead. During the 1960s and 1970s, many futurist groups were formed, including the World Future Society in 1966.

Sir Arthur C. Clarke was another leading futurist and active member of the World Future Society, as well as a foreteller of global network communication satellites. He maintained that no one could predict the future but it was feasible to map "possible futures." Other futurists, some more specialized than their predecessors, include Ray Kurzweil in the field of artificial intelligence, Eric Drexler in nanotechnology, Patrick Dixon in business, Arnulf Grubler in energy and environment, and Greg Stock in genetic engineering.

Today, futurists can include professional and academic visionaries, consultants, policy analysts, professors, and writers from many disciplines, including anthropology, computer science, economics, education, engineering, environmental science, history, library and information science, mathematics, physical sciences, political science, and sociology.

Regardless of a futurist's profession or academic expertise, all encourage "big picture" or cross-disciplinary thinking. According to futurist Edward Cornish, there are six "super trends" to understand if one wishes to see the big picture or the "Great Transformation" of what is shaping our future. They include technological progress; economic growth; health improvement; mobility increase; environmental decline; and deculturation. Futurists may advise companies, government agencies, and various organizations on possible scenarios and outcomes based on these super trends.

Based on these trends, futurists, or futurologists, employ a wide range of methodologies to examine and forecast the possible, probable, and preferable. The "possible" refers to what *could* happen; the "probable" refers to what would likely happen under circumstances subject to human control; the "preferable" is a prescriptive judgment as to what *should* happen. Forecasting is the attempt to estimate or predict future conditions based on current trends. It is important to define time periods in regards to short-term (1 to 5 years), medium-term (5 to 20 years), and long-term (20 to 50 years or beyond) forecasting of the future.

Another method often employed is that of "backcasting"—asking what changes in the present would be required to arrive at foreseen alternative futures. It is useful to analyze the many possible points of divergence from a timeline, as forecasting will construct multiple scenarios. Scenarios are one of the more popular methods used in futurology, especially by government, corporate, and military analysts who use them to aid decision making. A scenario is not a precise forecast of the future, but a probable description of what might happen. Driving factors of a situation are identified and plausible scenarios based on different outcomes are constructed.

The Delphi method is a type of forecasting that involves a panel of experts who judge the timing, probability, and implications of situations, trends, and events surrounding a particular problem. Participants maintain anonymity, frequent feedback is given, and the process is repeated several times until a consensus emerges. This method was used by RAND experts during the Cold War when they were asked to give their opinion on the probability, frequency, and intensity of possible enemy attacks.

In any attempt to forecast the future, a certain amount of risk, uncertainty, and unpredictability will exist. When the theory becomes more specific or forecasts farther into the future, the amount of uncertainty increases. This topic of uncertainty and unpredictability of forecasts is a source of controversy and debate among futurologists. Some argue that the future is at heart unpredictable, and that the true way to predict the future is to create it yourself. Others believe that advances in science, technology, models, and statistics will allow us to improve our understanding of probable futures.

Futurology is not only a discipline or profession, but also a state of mind. Futurologists have a passion and a skill for visualizing the risks and opportunities that we may face and how we can shape our futures.

G

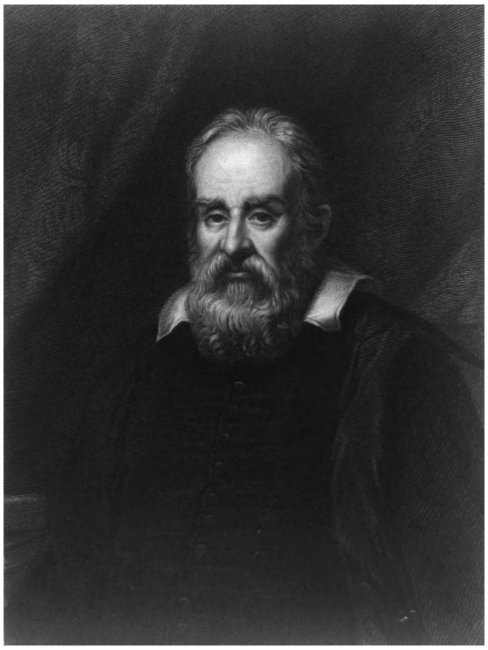
GALAXIES, FORMATION OF

See NEBULAR HYPOTHESIS

GALILEI, GALILEO (1564–1642)

Italian mathematician, astronomer, and physicist Galileo Galilei is considered to be the founder of the modern scientific method. He pioneered verification by experimentation and critical analysis of phenomena. Galileo was the first person to use a telescope to make and interpret systematic astronomical observations and made many discoveries regarding the solar system. Galileo's observations of the eclipses of Jupiter's moons led to his discovery of a cosmic clock that, in effect, recorded absolute time. The Galilean transformations of space and time variables led to the development of the Newtonian laws of mechanics. His theoretical work in physics laid the groundwork for the future exploration of relativity and the laws of motion. Although Galileo himself did not invent the pendulum-regulated clock, his initial designs inspired others to do so. His preliminary research and design of an escapement mechanism led to the development of the first pendulum-regulated timepiece. Galileo's quest to measure very small quantities of time accurately paved the way for discoveries about sound and light waves that eventually led to modern investigations of quantum physics.

Galileo was born in Pisa, Italy, on February 15, 1564. He was the first of six, possibly seven children born to Vincenzo Galilei, a musician, composer, and wool trader; their mother was Giulia Ammannati of Pesscia. Three days later the famous artist Michelangelo died. Leonardo



Galileo first put forth his observations on the moons of Jupiter in his book Siderius Nuncius. *He studied Jupiter over the course of a month and was able to show the movement of the satellites around Jupiter.*

Source: Library of Congress, Prints & Photographs Division, LC-USZ62-7923.

da Vinci had passed away 45 years prior to Galileo's birth. Nicholas Copernicus had been dead for 21 years. William Shakespeare would be born 2 months later. This was the time of the Renaissance. A new awakening had arrived for philosophy, music, art, the sciences, literature, and discovery.

Early Life

At age 7, Galileo was sent off to a monastery to prepare to study medicine. Galileo enjoyed life at the monastery and soon decided he wanted to become a monk. His father did not agree and, complaining about his son's untreated eye infection, removed Galileo from the monastery. Back at home young Galileo was strongly influenced by his father's experiments on the nonlinear relationship between the tension and pitch of stretched lute strings. Working with his father, Galileo learned how to experiment and gather data. By attaching carefully measured weights to a range of strings of different lengths and thicknesses, the Galileis listened to the tones produced. Each modification altered the frequency of the vibration, producing a different note. The length of the string altered the pitch, or cycles per second of the vibrating string, in much the same way the rate of the swinging of a pendulum was related to the length of its cord. This led to the discovery that the interval between two notes was related to the inverse squares of the length of the string, when the same weight was attached and the same interval observed. For a vibrating string, the frequency or sound heard is inversely proportional to the square root of the string's weight per unit of length, so thicker, heavier strings produce lower notes. This mathematical law contradicted traditional musical theory. Galileo learned from his father that it was foolish to accept anything as truth without examining the evidence in support of it. He was taught in the tradition of Plato's student Aristotle that theory must follow facts. It has been argued that Galileo's devotion to the Catholic Church inspired him to seek evidence about the world in order to protect the church from disseminating misinformation.

Contributions to Medicine

In 1582, at age 18, Galileo began his study of medicine at the University of Pisa. Years later, Galileo wrote about the state of medical education by describing an anatomical dissection. The topic was the origin of the nervous system. According to Aristotle, the heart was the source of the nerves, but the anatomist clearly demonstrated the brain was the true source of the nerves. The Aristotelian philosopher replied that the evidence before his eyes would clearly indicate the brain as the origin of the nerves and he would believe it to be so, if it were not for the words of Aristotle!

While attending services at Pisa's cathedral, Galileo noticed a swinging lamp and, using his resting heart rate as a timepiece, he observed that each swing of the lamp appeared to take the same number of pulses in his wrist and therefore approximately the same amount of time, regardless of the length of the swing. One could imagine him reminiscing about weights hanging from lute strings at home. His observations and discussions of this isochronicity of the pendulum led a friend of his, Santorre Santorio, a physician in Venice, to design a small pendulum that could be used to calibrate the human heartbeat rate. This device, called the *pulsilogium*, could be used to get an objective measurement of the heart rate of a medical patient. By observing changes in the pulse rate, physicians could now obtain data on the vitality of their patients and the efficacy of their treatments. In addition, Galileo was the first to invent a device to measure changes in temperature. With Santorio, Galileo worked to improve the science of experimental medicine, including the study of human metabolism. Although Galileo chose not to complete his study of medicine, his research led to major contributions to the scientific study of human anatomy and physiology.

Physical and Mathematical Investigations

Leaving the study of the medical arts behind, Galileo embarked on a lifelong journey in mathematics. Galileo's exploration of the geometry of Euclid of Alexandria and the physics of Archimedes of Syracuse and of Aristarchus of Samos inspired his creative genius. Stimulated by exploration of the foundations of astronomy from Hipparchus of Samos and Claudius Ptolemaeus, Galileo's mind was preparing to wrangle with ideas of cosmic proportions. Here Galileo cultivated a philosophy of scientific realism and a belief that there were explanations for natural phenomena that are revealed through observation and reason.

Inspired by the story of Archimedes and the golden crown of suspect purity, Galileo experimented with floating objects and developed a precise balance scale he called the *hydrostatic balance,* which could compare the weight of an object to an equal volume of water. He described this invention in a book he titled *The Sensitive Balance* (*La Bilancetta*) in 1586. He would later use measured volumes of water to calibrate elapsed time precisely in his acceleration experiments.

In 1587, Galileo was asked to cast a horoscope for Francesco de Medici, the Grand Duke of Tuscany. Galileo had disdain for astrology, which he considered to be heretical, but felt it was unwise to thwart the wishes of this generous benefactor. Drawing up a chart for the 46-year-old Grand Duke, Galileo announced that it indicated a long and fruitful life. Within a week the Duke was dead. In January of 2007, an analysis of the Duke's remains revealed an extremely elevated level of arsenic that was indicative of deliberate poisoning.

By 1593, Galileo had moved to the University of Padua where he taught mathematics and military engineering. It was here that he met and fell in love with Maria Gamba. While never married, they did have three children. His two daughters entered the convent and his son Vincenzo was by his side when he died. Galileo worked on many inventions, including a device that used horses to raise water from aquifers. In 1604, a "New Star," as it was called then, appeared in the constellation Sagittarius. Here was evidence for all to see that the heavens were not fixed and permanent, as Aristotle had decreed. If the great philosopher Aristotle could be wrong about this fundamental quality of the heavens, what else could he be in error about? We now know that what Galileo had witnessed was not a new (Nova) star, but rather a very old star in its last stages of stellar evolution.

Financial success came from Galileo's invention of a military compass that could be used to calculate the ideal firing angle for cannons as well as the gunpowder charge and projectile weight for maximum effect and accuracy. A civilian compass model that could be used for land surveying followed. This invention is considered by many to be the world's first pocket calculator. His text describing the use of the compass, titled *Operations of the Geometric and Military Compass (Le Operazioni del Compasso Geometrico e Militare)* was published in 1606. This invention also introduced Galileo to the unpleasant world of patent infringement, as he eventually had to prove that others had copied his work.

Galileo's lecture series on the location, shape, and dimensions of Dante's Inferno helped to earn him a 3-year appointment at the University of Pisa to teach mathematics. It was there, according to legend, that Galileo demonstrated that falling bodies of varying sizes and weights fell the 54 meters from the top of the Leaning Tower of Pisa at the same rate. By disproving one of Aristotle's alleged laws of nature, Galileo showed that blind acceptance of doctrine must yield to scientific experimentation. Galileo was adept at thought experiments. He reasoned that if two weights, one heavier than the other, were supposed to fall at different speeds, then why did hailstones of a wide range of weights fall together? He also pondered the question of whether, if a lighter and heavier weight were tied together, their rate of descent would change. Galileo asked whether, if the two were tied together, would the lesser one subtract velocity from the fall or would the two weights added together increase the rate of fall? If the lighter one subtracted velocity from the heavier one, then they should fall more slowly. Or, if the two together now weighed more than the original, would they fall all the faster? His conflicting results led inevitably to the conclusion that they must fall at the same rate regardless of their weight. Galileo used these kinds of thought experiments to help others to visualize the fundamental elements of motion.

When the objection was raised that a feather did indeed fall much more slowly than a cannonball, Galileo realized that air resistance accounted for the difference and that if this variable could be controlled, the two objects would fall at the same rate.

Galileo experimented with resistance in different media such as water and oil. He was not able to perform the experiment in a vacuum, the production of which was then technically unattainable. In July of 1971, 365 years later, Apollo 15 astronaut David Scott dropped a falcon feather weighing 0.03 kilograms and a geological hammer weighing 1.32 kilograms from a height of 1.6 meters on the moon. With no air resistance, they landed simultaneously, and Commander Scott duly noted that Galileo had been right.

Galileo sought an accurate way to measure the change in the speed of a falling object over time. Galileo, a talented musician and composer, had a well-developed internal rhythm and would be able count off beats in his head quite accurately to measure seconds. The tools available to measure time in those days were extremely limited in accuracy and reliability. Sundials and hourglasses would be useless to measure the brief intervals that Galileo sought to investigate. Mechanical clocks had appeared in Western Europe around 1330. A few years later a clock was built by Giovanni de'Dondi in Padua, Italy, that displayed the position of the sun, moon, planets, and the timing of eclipses. It was beautiful to behold, but its accuracy was limited. The timepieces available to Galileo could measure hours with reasonable accuracy; however, the quantities of time involved in calibrating acceleration would require accuracy not just to the minute, but to the "second minute," which we now know as the "second." It appeared to be virtually impossible to calculate events occurring in fractions of seconds.

Galileo needed a way to quantify time objectively. He tackled this daunting problem from two directions. First he devised a way to slow the falling object's rate of speed. By building a diagonal ramp he, in effect, diluted gravity. Now he could study acceleration at a more leisurely pace by rolling a ball down the highly polished inclined plane. Using his military compass, he could carefully determine the angle of descent of the plane. The second part of the problem involved measuring very small intervals of time. His familiarity with the lute would most likely lead him to include frets or slightly raised ridges on some of his inclined planes. By doing so, he could hear the ball striking the frets as it descended. By spacing the frets in a way that the time interval between each sound was identical, Galileo would have a measurable unit of distance to indicate acceleration. He had previously measured the isochronicity of a pendulum's swing using his own resting pulse rate; but from his observations with the pulsilogium, he knew that the pulse rate was too variable and therefore not a reliable enough clock to gauge acceleration. Added to this was another element arguing against using his own pulse as a clock. As his experiments began to reveal the laws of motion, his excitement would no doubt raise his pulse rate, rendering the measurement useless.

Another of his inventions, the hydrostatic balance scale, would provide the inspiration for a quantifiable unit of acceleration. Galileo designed a water clock to measure velocity indirectly. By starting the ball down the ramp and beginning the release of water simultaneously, and stopping the flow of water when the ball reached the end of the ramp, he could weigh the amount of water released in a given time. In this fashion Galileo was able to make an accurate comparison of the amount of time a rolling object spent in each portion of its descent down the ramp. He found that the distance the ball rolled down the plane was proportional to the square of the elapsed time. Galileo observed that balls of different weights increased their speed at the same rate. The development of modern science is based on the idea of mathematically measurable sequences. One such measure, a unit of acceleration, is known as a "Galileo." Galileo's struggle with the accurate measurement of time laid the foundation for those who followed. His calculations would be used in 1687 by Sir Isaac Newton to formalize the laws of motion in *Principia Mathematica*.

Another observation of nature that stimulated Galileo's inquisitive mind was the apparent difference between the speed of light and the speed of sound. Since lightning precedes thunder and the cannon's flash precedes the boom, Galileo knew that here was another mystery that could be solved mathematically. He attempted to design an experiment using lanterns spaced miles apart but could report only that light traveled so much faster than sound that light speed could not be measured with the instruments available at the time. Today, scientists can measure time to the attosecond, which is one quintillionth of a second!

Optics and Astronomy

While visiting Venice in 1609, Galileo first heard of the spyglass that a Dutch spectacle maker had invented. Galileo realized that a device that made distant objects appear closer had obvious military and potential financial value. His prior experience with the military compass and artillery inspired him to improve and capitalize on this invention. By experimenting with various combinations of concave and convex lenses he was able to improve on the original design by increasing its magnifying ability and righting the image. Without the proper combination and spacing of lenses, images appeared upside-down. Viewing an upside-down ship with the sea above and the sky below was disconcerting and detracted from the general usefulness of the spyglass. Galileo presented his improved 10-power telescope to the senate of Venice and demonstrated how ships at sea could be identified as friend or foe hours before a look-out without such a device could make such an identification. He was proclaimed a genius and given a generous salary increase and lifetime tenure. This granting of tenure, along with the appearance shortly thereafter of a large influx of cheap spyglasses from Northern Europe, angered some and may have contributed to problems he would face later in life.

Galileo continued to improve his telescope. With higher magnifying power and improved lens shaping and polishing techniques, he began his observations of the heavens. His preliminary investigations of the moon immediately revealed that it was uneven, rough, and full of cavities, craters, and prominences. It was not the smooth, polished, perfect heavenly body everyone believed it to be. By carefully observing the shadows cast by lunar mountains, he was able to make estimates of their altitudes. To those who insisted that the moon was covered with a smooth transparent crystal, he replied that they should grant him the equal courtesy of constructing with that same crystal mountains, valleys, and craters.

Galileo's explorations of the night sky brought new discoveries every clear evening. The Milky Way, which was considered to be a pale vapor of light, revealed itself to be an uncountable number of stars vast distances away. The Seven Sisters, a star cluster also known as the Pleiades, in the constellation Taurus the Bull, when magnified became hundreds of stars. The Great Sword of Orion, when closely examined displayed a marvelous cloud embedded with tiny newborn stars. Galileo's examination of Ursa Major, the Great Bear or Big Dipper or Plough, revealed an amazing double star that he observed during a failed attempt to measure parallax and therefore demonstrate Earth's revolution around the Sun.

In January 1610 Galileo turned his new and improved telescope on Jupiter. With modifications to the lenses, Galileo was now able to magnify the apparent diameter of an image 30 times. He noted a star to the left of Jupiter and two on the right, all in a straight line. One could only imagine Galileo's amazement when on the next evening he saw that all three of the stars were now on the left and still in a straight line. Weeks of observations and further improvements that widened the field of view of his telescope revealed a fourth star that circled around Jupiter. Galileo realized that these were moons that orbited Jupiter just as our moon orbited Earth. Here was evidence that not everything revolved around the earth. Seeing Jupiter's moons revolve around Jupiter also discredited the idea that if the earth revolved around the sun it would leave its moon behind. Additional calibration of the orbits of Jupiter's moons inspired Galileo to consider that their regular orbital periods could serve as a cosmic clock for ships at sea. This could aid in the accurate timekeeping that was essential for the determination of longitude. Galileo continued his telescopic observations and developed a table of the eclipses of Jupiter's moons to be used by ship's captains as a cosmic timepiece to determine longitude while out of sight of land. He even developed a telescopic device one could wear like a hat to observe Jupiter while keeping the hands free to pilot the ship. Apparently it was difficult to use and was abandoned. Galileo did notice a slight abnormality in the timing of eclipses of Jupiter's moons. It was not until 66 years later, in 1676, that the Danish astronomer Oleaus Romer was able to calculate that the 10-minute systematic error of Jupiter's observed synodic period was because light does not travel instantaneously. Years later it would be understood as a function of the varying distance between Earth and Jupiter. This parallax effect is a manifestation of our changing viewpoint as we revolve around the sun. Galileo named Jupiter's moons the "Medician Moons" in honor of his benefactors. Simon Mayr created the names we use today—Io, Europa, Ganemede, and Callisto—in 1614.

Galileo observed the planet Mars and saw that its apparent diameter increased when it was closer and diminished significantly when it was farther away from Earth. This was additional evidence that Mars revolved around the sun. When Mars and Earth were on the same side of the sun, Mars appeared twice as big as it did when Mars was on the far side of its orbit around the sun. This could not be clearly seen with the unaided eye, but was readily apparent when viewed through the telescope. In his honor, there is a crater on Mars called Galilaei as well as an asteroid named Galilea.

Another important observation first made by Galileo was that the planet Venus showed phases like the moon. When it was at its greatest distance from Earth, and more directly illuminated by the sun, it appeared as a small sphere. As its orbit took it around the sun and closer to Earth, it appeared as a progressively larger waning crescent. These observations lent credence to the Copernican idea that the sun was at the center of the solar system. Countless hours of watching the planets convinced Galileo of the validity of the Copernican heliocentric view. Seeing sunspots parading across the solar disc clearly demonstrated that our star, the sun, was not the perfect heavenly object described by the ancients.

Galileo was fascinated and perplexed by his observations of Saturn. The limited resolving ability of his telescope rendered a tiny, blurry image of Saturn and its ring system that was not a sphere like Jupiter but looked rather elongated or shaped like an American football. Could this be more evidence against the Aristotelian belief in perfectly spherical heavenly bodies? Galileo assumed that he was seeing three separate bodies. It is interesting to note that Galileo's observations of the planet Saturn led to an ironic cryptic message. In a coded letter, Galileo wrote that the last planet was triune or three-mooned. In the year 2005, the Hubble space telescope revealed that Pluto, which was considered at the time to be the last planet in our solar system, had three moons, which were named Charon, Hydra, and Nix. A contemporary analysis of Galileo's notes indicates that he probably was the first person to observe the planet Neptune, in the year 1612.

Galileo described his astronomical observations made using a telescope in a small book he called *The Starry Messenger (Siderius Nuncius)* in March of 1610. It received a great deal of attention and generated much heated discussion. In it, Galileo explained his view of scientific realism. He was certain that there were explanations of natural phenomena that would be revealed through observation and reasoning. There were those who felt that some of Galileo's findings contradicted the teachings of the Catholic Church. Objections were raised that certain passages in the Bible appeared to indicate that the sun went around the earth and that to believe otherwise was heresy. Galileo responded that while the Bible could never be wrong, it was not meant to be taken literally and that mistakes of interpretation could lead to confusion. This led others to complain that only the clergy could interpret the Bible and that Galileo had to be stopped. With the Protestant Reformation of Martin Luther and John Calvin and The Thirty Years War to contend with, the Catholic Church had little tolerance for dissension within the ranks. Galileo had met Giordano Bruno, who in 1600 was found guilty of heresy and burned to death. He knew others who had suffered at the hands of the Inquisition and was aware that he had better tread lightly. An investigation of the charges against Galileo found him innocent of heresy, but he was cautioned not to teach the Copernican system as a proven fact.

In 1618, three comets were visible over Europe. A Jesuit mathematician, Father Horiatio (Orazio) Grassi, who wrote using the pseudonym Lotario Sarsi, argued that the highly elliptical orbit of the comets argued against Copernicanism, which postulated circular orbits. Galileo replied in an essay titled *The Assayer (Il Saggiatore),* published in 1623. Here Galileo established norms and rules for the investigation of nature. It is considered to be one of the great works of scientific literature. In it, Galileo describes how the grand book of the universe is written in the language of mathematics.

Geocentrism, Heliocentrism, and Conflict With Established Authority

Galileo's attraction to the sea and things nautical led him to a contemplation of the causes of the tides. He believed that here he would develop the strongest evidence for Earth's motion around its axis and around the sun. As it turned out, he was wrong in discounting the moon's influence on the tides, which is much greater than the influence of the sun. Galileo sought permission from Pope Urban VIII to write a book about the motions of the solar system. The pope agreed, provided that the book gave a balanced view of the two conflicting theories of geocentrism and heliocentrism. The pope also requested that Galileo mention the pope's personal views that the heavenly bodies may move in ways that man cannot comprehend. Instead of writing his findings in the form of a scientific report, Galileo choose to present his ideas as a conversation among three individuals. *His "Dialogue Concerning the Two Chief World Systems: Ptolemaic and Copernican" (Dialogo sopra i due massimi sistemi del mundo, tolemaico e copernicano)* was published in 1632. The December 2006 issue of *Discover* magazine listed Galileo's *Dialogue* as the fourth greatest scientific book of all time. This dialogue featured a character named Salviati, a proponent of Galileo's ideas. Salviati's heliocentric or sun-centered views were presented as witty, intelligent, and well informed. Sagredo, the bystander, who served as the mediator, was usually persuaded by Sagredo. Simplicio, the proponent of geocentrism or an Earth-centered solar system, was portrayed as somewhat slow-witted and easily befuddled. As an expert on Aristotelian thought, Simplicio represented those who ignored evidence and preferred to cling to dogma rather than explore new ideas. The dialogue on the two great systems of the world presented Copernican theory as the logical and intelligent man's preference. It was considered by many to be a literary and philosophical masterpiece. It was considered by Pope Urban VIII to be a grievous insult to have his views presented by the dim-witted character Simplicio, the simpleton.

Word reached Rome that Galileo was teaching Copernicanism; and worse, it was suggested that he had modeled the fool in his dialogue after the pope. Some said that *The Dialogue* made a mockery of the pope's intellectual authority and undermined his temporal power. Galileo had, in effect, challenged the Catholic Church's authority in the interpretation of scientific knowledge. He was ordered to appear before the Holy Office of the Inquisition to face charges of heresy. Aware of the potential for torture and death, Galileo confessed that he had been wrong to say that the earth moved around the sun. Galileo was found guilty of suspicion of heresy and forced to recant his heliocentric beliefs. He was sentenced to life imprisonment, later commuted to house arrest, and forbidden to discuss his views with anyone. Publication of anything he had written or would write in the future was forbidden. It is interesting to note that Copernicus had never been accused of heresy and that his book, *De Revolutionibus,* was not banned but rather withdrawn for corrections. In his 2001 book, *Galileo's Mistake,* author Wade Roland argues that the church's main problem with Galileo was not his belief in the Copernican system but rather in Galileo's belief in a mechanistic, materialistic philosophy that seeing is believing.

While confined to his home, Galileo continued to investigate other areas of science. He applied mathematics to a variety of problems. He explored geometry and went from the study of lengths, areas, and volumes to the contemplation of motion, mass, and time. For his last, and some consider his greatest, literary masterpiece he returned to the literary device of three gentlemen discussing a wide variety of issues and arguing their points of view. Here, Galileo developed the fundamentals of relativity. He went into great detail regarding the nature of matter. Galileo was able to have his notes smuggled out of Italy and published in 1638 by a Dutch publisher named Luis Elzevir as *Discourses About Two New Sciences* (*Discorsi e dimostrazioni matematiche intorno a due nuove scienze*). This work proved to be the foundation for the modern science of physics.

Galileo's last astronomical discovery was the lunar librations. Galileo discovered that the moon's equator is inclined to its orbital plane. This causes a slight wobble in the moon's axis and allows us to see a bit of the far side of the moon periodically. A lunar crater 15 kilometers in diameter is named in honor of Galileo. It is located just west of the one named for Copernicus.

Galileo and Modernity

At the end of his life, Galileo, who had seen farther than any man before him, became completely blind. He passed away on January 8, 1642, with his son and students by his side. Isaac Newton was born 11 months later. Newton referred to Galileo when he said that the reason he had seen farther was because he had stood on the shoulders of a giant. Stephen Hawking, the Lucasian Professor of Mathematics at Cambridge University and author of *A Brief History of Time,* describes Galileo as the single individual most responsible for the birth of modern science. He notes that Galileo was one of the first to argue that man can understand how the world works by observing the real world.

It was not until 99 years after Galileo's death, in the year 1741, that Pope Benedict XIV lifted the ban on Galileo's scientific works. In 1979 Pope John Paul II asked the Pontifical Academy of Sciences to conduct an in-depth study of the Galileo case. In 1992, the church formally and publicly cleared Galileo of any wrongdoing, 350 years after his death. Pope John Paul II expressed regret for how the Galileo affair had been handled. In his summary of the conclusions he noted that Galileo showed himself to be more perceptive of the criteria for scriptural interpretation than the theologians who opposed him. The pontiff paraphrased Saint Augustine's words that truth can never contradict truth, and that where the Holy Scriptures appear to contradict the natural world, it is the error of interpretation that must be resolved.

Gamow, George (1904–1968)

George Gamow, Russian-born physicist, was noted for his contributions to interdisciplinary understanding and for his synthesis of modern physics with both a cosmological and evolutionary framework. Taking a comprehensive view of modern physics, Gamow presented the evolution of the universe and human life as a chance product of chemical interaction/reaction within the spatiotemporal parameters of the universe. From the initial theory of the big bang that resulted in our expanding universe, the conceptual framework of time, space, and distance poses unique problems for both traditional physics and scientific epistemology. Gamow explained the impact of these problems and the theoretical basis for our current understanding of the universe and its implications for life on this planet.

The conceptual framework of time and humankind's perception of the natural world became the basis for continual theoretical advances. Gamow articulated this open-ended perspective by illustrating the historical progress, both philosophical and scientific, made in mathematical understanding of the physics that govern the universe. Contrary to cultural perceptions of the temporal and static nature of the universe, Gamow depicted the spatiotemporal nature of the cosmos as an expanding and temporally changing universe, filled with innumerable planets, stars, and galaxies. This uniform expansion of the universe was suggested as being approximately 2 to 3 billion years ago, with comparable ages of the oldest celestial bodies. The age of our solar system, specifically our planet and the sun, has deep implications for life. Although our sun and planet were estimated to be relatively young, around 3 to 4 billon years and 2 billion years, respectively, Gamow's calculations put the lifespan of our sun at around 50 billion years. Fueled by nuclear reactions within the bending of time and space, the birth and death of star(s) becomes a tethered line for life on this planet and possible life on other worlds. Though Gamow speculated on the probability of life elsewhere in the universe (including the immensity of distance between planets), the chemical sequence and the emergence of life from inorganic matter became a probability and a particular point of scientific wonder.

The spatiotemporal nature of the universe is paradoxical. Concepts of infinity within finitude are deeply rooted within the human psyche. Although new developments in mathematics, physics, and chemistry continue to inform our ever-growing understanding of the universe, these dual concepts of time seem to preclude any definitive and comprehensive theory of both life and the physics of the universe by which life itself is governed. Gamow's substantial contributions to cosmology, even in light of recent advances, allow us to appreciate more fully both the finitude of human existence and the need for further understanding of the complex relationships that obtain within the universe.

Gehlen, Arnold (1904–1976)

Arnold Gehlen is known as a cofounder of philosophical anthropology and was one of Germany's leading postwar sociologists; he was also a significant time diagnostician. His understanding of man as an organically "deficient being" paved the way for a theory of institutions that is not only substantial but also empirically adaptable. His anthropological views served asa foundation for his contemporary analyses of Western industrial societies, which were farsighted and, as a result of his conspicuous conservatism, also controversial at the same time.

Gehlen received his PhD in 1927 after studying under the philosopher and biologist Hans Driesch; 3 years later he qualified for a tenured professorship under, among others, Hans Freyer, after having written his habilitation. During the Third Reich, Gehlen had a shining career and quickly received professorships in Leipzig, Königsberg, and Vienna. After serving in the army's administrative council (1941–1942), he was sent to the front and was severely wounded. In 1947, after his denazification, he received his first teaching position as a university professor in Speyer, then later in Aachen, where he taught sociology from 1962 until his retirement.

Like most of his colleagues from Leipzig, Gehlen joined the Nazi Party in 1933 and became a member of the National Socialist German University Lecturers League. He demonstrated his approval of the National Socialistic regime in several ways; for example, in his inauguration lecture in Leipzig 1935. His reference to the "highest systems of leadership" in his first anthropological study (1940) can also be understood as opportunistic. Such declarations of loyalty were never part of Gehlen's scientific thinking, however. His understanding of man as a deficient being (*Mängelwesen*) did not refer to any racial differences. In his opinion, from a biological point of view the "Aryan" is as inadequate as every other human race. Consequently, Gehlen's anthropology was contrary to official Nazi ideology from the beginning; and he himself was always considered an "uncertain type" by Nazi leadership.

Gehlen's ideological home was not totalitarian National Socialism. It was the world of conservative thinking and order. So it is possible to find him referring specifically to the tradition of political thought where the state was the center of focus—as in the work of Hobbes or Hegel. But Gehlen's philosophy was also influenced by many other ideas that were quite diverse: His first phase was shaped partly by existentialist ideas, which are dealt with in his 1931 dissertation. His intensive study of German idealism, especially Fichte, influenced his theory of the freedom of the will and characterized, to a certain extent, the second phase of his work. His anthropological phase began specifically in the mid-1930s. During that period of time Gehlen was one of the first German philosophers to discover American pragmatism, particularly citing the works of John Dewey and George Herbert Mead. The philosophy of life (Schopenhauer, Nietzsche, Bergson) had a major influence on Gehlen's research; he also dealt with Driesch's concept of neovitalism in his dissertation. In the end, the idea of combining philosophical and anthropological studies may have been enhanced by the transdisciplinary atmosphere at the University of Leipzig, which included, among others, the sociologists Hans Freyer and Helmut Schelsky, the psychiatrist Hans Bürger-Prinz, and the philosopher Gotthard Günther.

Works and Ideas

Gehlen's main anthropological work, *Man, His Nature and Place in the World,* was first published in 1940 and has been reprinted several times. In his study of late-modern civilization (1956) Gehlen worked on the deficits of his concept of action, which had essentially been instrumentally conceived, and presented a differentiated institutional theory. His highly acclaimed writings *Man in the Age of Technology* (1957) and his 1969 work on ethics were particularly relevant from the perspective of critical time diagnostics.

The main concern of philosophical anthropology consists of discussing questions that deal directly with the way humans see themselves. According to Gehlen, it is in this context that it is of primary importance to cast off idealistic ballast and to overcome the dualism of the body and the soul. Gehlen begins with a concept of action: Like Nietzsche, he sees in man the "still undetermined animal," a being whose life is at risk. Man cannot feel secure in his environment because he lacks protective instincts. As a result of his deficient biological makeup there is no natural environment for him. Everything and everyone can be his enemy. So man has no other alternative but to create his own relationship to the world around him and to himself through his actions. Man's nature is civilization: Man not only has a life, he needs to lead a life—and thus compensates for his deficient being.

Yet, following Gehlen, man is not only at the mercy of his environment; he is also dangerous. Vague but driven by physical desires, he is latently subject to the danger of mutating, becoming an enemy of his own kind or even of himself. So he doesn't just have to lead his own life, he also has to be led, in particular by institutions. Institutions are the substitute for missing instincts; they give man something to hold onto by requiring him to act in a certain way. Their "unquestioning manner" of guiding human behavior in certain directions relieves the individual of the duty to constantly make decisions. For instance, a letter must be answered—at least in times of postal communication; it requires contemplation, at best concerning the content; but this is also simplified by use of socially standardized forms of address, endings, gratitude, and more. In Gehlen's opinion, institutions are therefore different from mere organizations. They don't serve just one particular purpose and then lose their significance when the job is done. They are created by mutual social interrelations within a community that they also symbolize. Consequently, institutions possess an inherent worth that commits the individual and motivates him to act.

In his writings on time diagnostics, Gehlen especially points out the social processes that develop a force capable of destroying institutions: They are closely connected to a technology that pervades all areas of existence and leads to a degradation of human senses and an intellectualization of life. Everything seems possible, everything can be tried out—in this sense, "anything goes" exemplifies the typical contemporary attitude, in Gehlen's opinion; it is of an experimental nature but also nonbinding and formal, supported by a subjectivism that constantly calls for self-identity: Everyone can imagine everything. The real world becomes virtual in the process of a continuous "psychologization." In order to evoke a response, the cause has to be catchy and easy to remember, never subtle, and preferably shrill. Today's world, as Gehlen said back then, is trivial and busy—unproductiveness at high speed, a racing standstill.

So it is easy to assume that modern society has come to an end. Things could still be recycled and combined, but man has essentially reached the end of history. Man in modern times has come to accept this inevitability from which he can no longer be lured—"*rien ne va plus*."

Gehlen's thesis has been extensively criticized, one objection to his anthropology of the deficient being is that it is too pessimistic. The deficits of man are exaggerated in comparison to his rational abilities, which enable him to be highly flexible and adaptable. Furthermore, by profoundly emphasizing the differences between man and animal, the variations of human existence are completely neglected. Specifically from an ethical point of view, it is of utmost importance to differentiate between the human and the inhuman, but Gehlen's theory leaves no room for such thoughts. Similarly, a great deal of criticism targets the lack of criteria used in his institutional theory. Gehlen's approach is concerned only with the stability and justification of the status quo. From today's perspective, a large part of this criticism seems justified; basically it is necessary to criticize his philosophical as well as his sociological ideas for excluding substantial normative principles without omitting extensive critical evaluations of society. Nevertheless, people often do not realize that his action theory stresses man's openness and productivity in his relationship to the world and to himself. In that sense, it is possible to imagine that his institutional theory can be critically reconstructed within the framework of a normative intention.

Gehlen's primary achievement is that he developed a theoretical view of society that does not simply deal with individual rational actions or the structures of social systems. It also points out the links between the individual and the system that serve as the basis for his time diagnostic analyses. By using these analyses, it is possible to discover the grayness of an apparently modern conformity amidst the colorful world of new postmodernism.

Genesis, Book of

Genesis is the first book of the Hebrew Bible and Christian Old Testament. The basic premise of this book is to recount the stories of the Hebrew patriarchs and their covenant relationship with God. The Book of Genesis connects the God of the patriarchs with the beginning of time as the creator of the universe.

The book is a book of beginnings, as its Hebrew title suggests—*bĕrē'šît* meaning "In the beginning." The name "Genesis" comes from the transliteration of the Greek for the first word of the book, which means "origins." Both titles appropriately describe the contents of the Book of Genesis. The book tells of the creation of the universe, the dawn of humanity, the origin of sin, and the beginning of the Hebrew people.

The book centers around the promise God gave to Abram (renamed Abraham, Gen 17:5), which is to make him the father of a multitude of people who would become a nation (12:1–3) living in a specific land (13:14–15). This promise divides the book into two sections. The first part (chapters 1–11) explains how the world came to be, why it is the way it is at the time of Abraham, and that God was involved the entire time. Time passes quickly in these chapters through genealogies that connect the stories of creation, the introduction of sin, the flood account, and God's promise to Abram. This section contains two stories of God creating the world, each having a different sequence of events. In the first account (1:1–2:3) God made light and separated it from darkness. Next he made the heavens, sea, and land, then the plants, then the sun, moon, and stars, and then he created the birds, fish, and land animals. Finally, God created humans, both male and female. This event completed Creation. In the second Creation account (2:4–25), God made the heavens and Earth and then he created a man named Adam. Next, God created Eden, an idyllic garden full of plants, where he placed Adam. Afterward, God created animals and birds and finally he made a woman whom Adam named Eve.

While Eve lived in the garden, a serpent had a conversation with her and deceived her. Adam supported her and silently consented. They yielded to temptation by eating forbidden fruit from the tree of the knowledge of good and evil and thereby introduced sin into the world. Sin quickly spread throughout Creation and intensified, as demonstrated in fratricide among Adam and Eve's two sons, Cain and Abel. During 10 long generations sin increased to such an intolerable point that God sent a flood to destroy the world with the exception of a righteous man, Noah, and his family. Noah built an ark that saved him from the destruction of the flood. After the flood, one of Noah's sons sins, an indication that the flood did not rid the world of this problem; thus God would have to find another solution. This dilemma leads to the promise to Abram, the next attempt at the problem of sin. Genealogies following the flood story provide an explanation for all the different people groups, nations, and languages in the world at the time of Abram and set the stage for Abram's appearance.

Genesis 12–50 is the second part of the book. Time in this section slows as the author concentrates on the stories of four generations of patriarchs—Abraham and his descendants—and their struggles to fulfill God's promise. Abraham, the original recipient of the promise, had various difficulties in producing children and staying in the promised land. His son Isaac had similar problems but managed to have twin sons who were in competition for their father's inheritance and blessing. Jacob, the victorious twin, had his own problems establishing a place for himself. However, God reiterated the promise to Jacob and changed his name to Israel. Jacob married two sisters and their two servants and produced 12 sons and a daughter. These sons became the fathers of and namesakes of the Twelve Tribes of Israel and they represent the birth of the nation.

The Book of Genesis ends with a series of stories about Joseph, one of Jacob's sons, and his adventures in Egypt. By the end of the book, not only was Joseph in Egypt but his father, all his brothers, and their families and flocks as well. This ending sets the stage for the Book of Exodus and God's deliverance of his people from Egypt to the promised land.

Thus the Book of Genesis describes God as the creator of the universe who created everything including the first humans. Because humanity's sin brought about the fall of Creation, Genesis tells that God took an active role in humanity's salvation and in world events. In doing so, the book covers a time from the beginning of the universe to the second millennium BCE.

Stories from the Book of Genesis, especially the Creation stories, have been used as common themes in literature throughout history from John Milton's *Paradise Lost* to Gary Larson's *Far Side* cartoons to the *Star Trek* movies.

Genghis Khan (c. 1162–1227)

The Mongolian emperor Genghis Khan's audacity and ingenuity fueled the vast expansion of the Mongol Empire during the 12th and 13th centuries, securing him a place of note in world history. His empire eventually extended over most of Asia, including portions of Russia.

Genghis Khan (born Temujin) remains among the most influential people of all time, having revolutionized the conduct of war and establishment of laws in addition to instilling fear and awe in those he led and those he encountered on the battlefield. As for military convention, Genghis Khan implemented tactics that helped the Mongol forces attain one of the largest empires in history. Dependent on well-trained cavalry, Genghis Khan's forces used hit-and-run tactics to disrupt and slowly carve away at enemy forces, beginning with enemy commanders. Genghis Khan's strategies made it possible to attack and disperse larger forces, reflecting the daring and brilliance of the Mongol leader so many came to fear. Arguably, it is these cunning tactics, along with his methodology of concealing his army's size and whereabouts, that ultimately won Genghis Khan land and reputation.

Though Genghis Khan's military tactics instilled fear in his enemies, it is his compilation of laws (*Yassa*) that reflects his understanding of people and adds considerable depth to his legacy. Genghis Khan incorporated longstanding traditions and his own decrees to formulate one canon of laws. This combining of the traditional and the contemporary ensured legitimacy for the Yassa and, consequently, for Genghis Khan's reign.

Chinggis, or Genghis, Khan is the title bestowed on Temujin on his attaining the Mongol throne. The year of Chinggis Khan's birth and the exact location of his tomb remain unknown, though several dates and locations have been postulated. Further, a complete copy of Chinggis Khan's Yassa has yet to be found, making it difficult to ascertain the extent of his transformation of traditions to generate his laws. What is known is that he created one of the greatest empires in history, employing both harsh and ingenious methods to do so. Chinggis Khan's death in 1227 is documented as to the day and his final actions as ruler, yet even with documentation from a number of texts, questions remain.

Portrait of warrior-ruler Genghis Khan (1167–1227), founder of the Mongolian Empire, 1200. One of history's more charismatic and dynamic leaders, Genghis Khan during his lifetime conquered more territory than any other conqueror, and his successors established the largest contiguous empire in history.

Geological Column

The geological column is a composite diagram that shows in a single column the vertical or chronologic arrangement of the subdivisions of geologic time, or the sequence of rock units of a given region. Geologic time includes the part of the earth's history that is represented by and recorded in the successions of rocks, or the time extending from the formation of the earth as a separate planetary body to the beginning of written history. Earth scientists use a common language to talk about geologic time. That common language is standard, and it is ruled by the Geologic Timescale (GTS). The modern GTS consists of two different scales: the relative timescale, which is made of chronostratigraphic units, and the chronometrical or absolute timescale, which consists of geochronologic units. Due to the complexity and duration of geologic history, both scales are divided into hierarchical levels that are used by historical geology to analyze the history of our planet and of life on Earth.

Principles and Development

The standard geological column represents an ideal succession containing rocks from all ages, the earliest rocks on Earth at the bottom of the column and the youngest ones at the top. The construction of the geological column is based on the underlying principles of stratigraphy, first proposed by Nicolaus Steno around 1669. According to his *principle of superposition,* the oldest stratigraphic units are located at the bottom of the column and the youngest at the top, with dips adjusted to the horizontal. The resulting geological column indicates the relations between the stratigraphic units and the subdivisions of geologic time, and their relative positions to each other. The principle of superposition is the basis for establishing the relative ages of all strata and the fossils that they contain.

The geological column was developed largely during the early 19th century, and its origin probably begins with the story of the first geological map of England, published by William Smith in 1815. Smith was the first to realize that fossils were arranged in order and regularly in strata, always in the same order from the bottom to the top of a section, each stratum being characterized by particular types of fossils. These observations led him to propose the *principle of faunal succession.* Furthermore, the relative order of the formations was proved to be the same even in distant locations of Great Britain. The application of these two simple principles (superposition and faunal succession) led to the construction of the first geological column. In addition, the geological column was based on the uniformitarian principles (the present is the key to the past, i.e., processes operating in the past were constrained by the same laws of physics that operate today) first proposed by James Hutton in the mid-18th century and further developed by Charles Lyell.

The standard geological column aims to establish a classification system to organize systematically the rocks of the earth's crust into formal units corresponding to intervals of geologic time. Such units must be of global extent to allow correlation. Among the formal units for stratigraphic classification, chronostratigraphic units—units based on the time of formation of the rock bodies—offer the greatest potential for worldwide application because they are based on their time of formation, and are therefore the most accepted units to mark positions in the stratigraphic column. Other units such as lithostratigraphic, biostratigraphic, and unconformity-bounded units are all of limited areal extent and thus unsatisfactory for global synthesis. The biostratigraphic units are nevertheless unique in the sense that the fossils they contain show evolutionary changes through geologic time that are not repeated in the stratigraphic record. Due to the irreversibility of evolutionary change, biostratigraphic units are indicative of geologic age. However, owing to the imperfection or incompleteness of the fossil record, and the dependence of the fossil-producing organisms on biogeography and depositional facies, the boundaries of the biostratigraphical units commonly lie at different stratigraphic horizons and, similar to unconformity-bounded units, they may be diachronous and represent all or parts of one or several chronostratigraphic units. Magnetostratigraphic polarity units approach synchronous horizons because their boundaries record the rapid reversals of the earth's magnetic field. Although magnetostratigraphic polarity units may be useful guides for chronostratigraphic position and have a potentially worldwide extent, they have relatively little individuality because one reversal looks like another, and they can usually be identified only by supporting age evidence. Therefore, magnetostratigraphic polarity units require extrinsic data such as biostratigraphic data or stable isotope analyses for their recognition and dating. All these stratigraphic units are based on one property each, and they will not necessarily coincide with those based on another.

Chronostratigraphic Scale

For convenience, a chronostratigraphic scale has been created to divide the rock record into chronostratigraphic units, which are relative time units. Chronostratigraphic units are divisions of rock bodies based on geologic time. They are studied in Chronostratigraphy, the branch of Stratigraphy that deals with the relative time relations and ages of rock bodies. The purpose of the chronostratigraphic classification is to organize systematically the rocks of the earth's crust into chronostratigraphic units corresponding to intervals of geologic time. These intervals of geologic time are called geochronologic units, and they actually measure time in years before the present. The geochronologic scale helps to calibrate the chronostratigraphic scale to linear time. Chronostratigraphy aims to provide a basis for time correlation and to create a reference system to record events of geologic history; in order to achieve these goals, the scale is standardized by the International Commission on Stratigraphy (ICS).

Chronostratigraphic units are tangible stratigraphic units because they encompass all the rocks, layer upon layer, formed within a certain time span of the earth's history regardless of their compositions or properties. By definition, they are worldwide in extent, and their boundaries, which are called chronostratigraphic horizons or chronohorizons, are synchronous, everywhere the same age. Whereas other kinds of stratigraphic units are identified on the basis of observable physical features, chronostratigraphic units are distinguished and established on the basis of their time of formation as interpreted from these observable properties. Several hierarchical levels may be distinguished among chronostratigraphic units, namely eonothem, erathem, system, series, and stage (from the most to the least comprehensive levels). Their rank and relative magnitude are a function of the time interval represented by their rocks. The oldest eonothem is the Archean, and it is followed by the Proterozoic, and by the most recent Phanerozoic. The names of the different erathems are related to the ideas of evolution, representing major changes of the development of life. The oldest erathem of the Phanerozoic is thus called Paleozoic, which means "ancient life," and it is followed by the Mesozoic, meaning "middle life," and by the Cenozoic, which means "recent life." The names of most formal stratigraphic units more commonly consist of an appropriate geographic name (usually, the geographical regions where they were first found and studied) combined with an appropriate term indicating the kind and rank of the unit. Position within a chronostratigraphic unit is expressed by adjectives indicative of position, such as basal, lower, middle, upper, and so on. Stages can be subdivided into substages or grouped into superstages. A stage is defined by its boundary stratotypes, that is, sections that contain a designated point in a stratigraphic sequence of almost continuous deposition, chosen for its correlation potential. The lower and upper boundary stratotypes represent specific moments in geologic time, and the geologic time between them is the time span of a stage (generally between 2 and 10 million years). Special attention is paid to the selection of the lower boundaries of chronostratigraphic units, since the upper boundary of a given chronostratigraphic unit corresponds to the lower boundary of the succeeding unit. Therefore, each chronostratigraphic unit is defined in the rock record by a boundary stratotype that is formally known as a Global Stratotype Section and Point (GSSP), which provides an unequivocal definition of the chronostratigraphic units in the stratigraphic record. If possible, boundary stratotypes must be identified in marine, fossiliferous, and continuous sections that are well exposed and easily accessible, and they should contain synchronous marker horizons that allow long-distance correlation. An example of a geologically synchronous boundary stratotype is the Cretaceous/Tertiary boundary stratotype, whose GSSP is located at the El Kef section in Tunisia. This boundary stratotype contains multiple markers, including evidence of the mass extinction of marine and terrestrial groups such as calcareous plankton or dinosaurs, the restructuring of other faunal groups such as benthic foraminifera, the deposition of a rusty-red layer with an anomalous concentration of iridium, microtektites, shocked quartz grains, and Ni-rich spinels, isotope anomalies (negative shift in C-13), and so forth. These palaeontological, mineralogical, geochemical markers are related to a global event, the impact of an asteroid on Earth, and they allow worldwide correlation of the Cretaceous/Tertiary boundary. Boundary stratotypes are important because, apart from defining stages, they also define series (whose time spans range from 13 to 35 million years) and systems (normally from 30 to 80 million years each).

A chronozone is a chronostratigraphic unit of unspecified rank, and it includes all rocks formed everywhere during the time span of some designated stratigraphic unit or geologic feature. Although chronozones are formal chronostratigraphic units, they are not part of the hierarchical chronostratigraphic classification.

Geochronologic Scale

The time during which a chronostratigraphic unit was formed corresponds to a geochronologic unit, which corresponds to a unit of time, a subdivision of geologic time. The geologic timescale is based on geochronologic units, and it is the time-intangible-equivalent to the physical geological column, which is based on chronostratigraphic units. Time cannot be found in a rock body, but we can assign a certain age to rock bodies through the analysis of tangible features. Therefore, the geological column can also be divided into geochronologic units. The geologic timescale is usually presented in the form of a chart showing the names of the various stratigraphic units, including chronostratigraphic units and geochronologic units. Unlike the chronostratigraphic scale, which is based on relative time units, the geochronologic or chronometric scale measures time in years before the present. The geologic timescale results from joining the chronostratigraphic and the geochronologic scales.

As in the chronostratigraphic units, several hierarchical levels can be distinguished among geochronologic units, namely eon, era, period, epoch, and age, with eons being the most comprehensive levels and ages the smallest levels. Eras are divided into periods, the periods are further divided into epochs, and the latter into ages. These units are equivalent to chronostratigraphic units: for example, an age represents the time during which a stage was formed and it takes the same name as the corresponding stage, and an epoch is the geochronologic equivalent of a series. Eras and eons take the same name as their corresponding erathems and eonothems. Position within a geochronologic unit is expressed by adjectives indicative of time, such as early, late, latest, and so on. The time span during which a chronozone was deposited corresponds to a chron. Although the *International Stratigraphic Guide* states that "a chronozone includes all rocks formed everywhere during the time span of some designated stratigraphic unit or geologic feature," most chronozones and their corresponding chrons are derived from previously established biozones or biostratigraphical units (bodies of stratified rocks that are characterized by their fossil content).

Standard Global Chronostratigraphic (Geochronologic) Scale

All units of the standard chronostratigraphic and geochronologic hierarchies are theoretically worldwide in extent. They provide a standard scale of reference, what is known as the Standard Global Chronostratigraphic (Geochronologic) Scale, that aims to date all the rocks everywhere and to relate all rocks everywhere to the earth's geologic history. The standard geological column and its equivalent geologic age system have been built up by superposition of local columns from many different localities. A local geologic column is called a "geologic section," and it consists of any sequence of rock units found in a given region either at the surface or below it. Although the geologic column is not found complete at any place on Earth and the representative sediments common to all the major divisions cannot be found all together in a single section, the relative order of the formations still remains the same; in addition, such relative order also fits the geologic column.

Geochronometry

The quantitative (numerical) measurement of geologic time is dealt with by geochronometry, a branch of geochronology. The improvement of radiometric techniques since 1917 has allowed scientists to determine the absolute ages of rocks and to work out the duration of the intervals of geologic time, which had been previously established by means of fossils. More recently, enhanced methods of extracting linear time from the rock record have enabled high-precision age assignments. Apart from high-resolution radiometric dating, some of these calibration methods include the use of geochemical variations, Milankovitch climate cycles, and magnetic reversals. Radioactivity allowed scientists to date chronostratigraphical units, contributing to the development of the modern GTS. Technologic advances in measuring magnetic properties of rocks, together with the intense drilling of oceanic sediments and their biostratigraphical calibration by means of microfossils, have led to an improved chronology (magnetobiochronology). Moreover, the rapid development of cyclostratigraphy during the past decades has led to the construction of an astronomical timescale for dating events in the geologic record, based mainly on the relation between sedimentological, geochemical, or palaeontological cycles and variations in the earth's orbital parameters.

Recent Developments and Future Directions

The construction of the geological column has been under way for the last 2 centuries, and it has overcome several obstacles such as the precision and accuracy of correlation and dating tools, the limits of the stratigraphic database, or problems of nomenclature. In March 2005 the current available stratigraphic and geochronologic information was compiled by the project "Geologic Time Scale 2004" and published by a team designated by the International Commission on Stratigraphy. The results of this project summarized the history and status of boundary definitions of all geologic stages, compiled integrated stratigraphy (biologic, chemical, sea-level, magnetic, etc.) for each period, and assembled a numerical age scale from an array of astronomical tuning and radiometric ages. A combination of zones, polarity chrons, stages, and ages was carried out in order to calculate the best possible timescale. Earth scientists thus keep concentrating their efforts on the construction and improvement of the GTS. Research on Ocean Drilling Program (ODP) cores, and on Integrated Ocean Drilling Program (IODP) cores in the near future, will improve the calibration of various biostratigraphical scales, and together with the development of new tuning strategies will probably extend the astronomical timescale downward. Even so, there are still some stratigraphic and geochronologic issues to be resolved in the next updated version of the Geologic Time Scale, the GTS2008, which is expected to include a consensus on all stage boundary stratotypes, which is one of the main challenges for the future.

Geologic Timescale

The geologic timescale is the framework for deciphering the history of planet Earth. It is used by geologists and other scientists to describe the timing and relationships between events that have occurred during the history of the earth.

Nomenclature

The history of the earth is broken up into a hierarchical set of divisions for describing geologic time. In increasingly smaller units of time, the generally accepted divisions are eon, era, period, epoch, and age. The Phanerozoic eon represents the time during which the majority of macroscopic organisms, algal, fungal, plant, and animal, lived. When first proposed as a division of geologic time, the beginning of the Phanerozoic, approximately 542 million years ago (mya), was thought to coincide with the beginning of life. In reality, this eon coincides with the appearance of animals that evolved external skeletons, like shells, and the somewhat later animals that formed internal skeletons, such as the bony elements of vertebrates. The time before the Phanerozoic is usually referred to as the Precambrian. The Phanerozoic consists of three major divisions: the Cenozoic, the Mesozoic, and the Paleozoic eras. The *zoic* part of the word comes from the root *zoo,* which means animal. *Cen* means recent, *meso* means middle, and *paleo* means ancient. These divisions reflect major changes in the composition of ancient faunas, each era being recognized by its domination by a particular group of animals. The Cenozoic has sometimes been called the age of mammals, the Mesozoic the age of dinosaurs, and the Paleozoic the age of fishes. This is an overly simplified view; it has some value for the newcomer but can be a bit misleading. For instance, other groups of animals lived during the Mesozoic. In addition to the dinosaurs, animals such as mammals, turtles, crocodiles, frogs, and countless varieties of insects also lived on land. In addition, there were many kinds of plants living in the past that no longer live today. Ancient floras went through great changes too, and not always at the same times that the animal groups changed.

Few discussions in geology can occur without reference to geologic time, which is often discussed in two forms: (1) Relative time (chronostratic), subdivisions of the earth's geology in a specific order based upon relative age relationships; these subdivisions are given names, most of which can be recognized globally, usually on the basis of fossils. (2) Absolute time (chronometric), numerical ages in millions of years or some other measurement. These are most commonly obtained via radiometric dating methods performed on appropriate rock types.

History

The first people who needed to understand the geological relationships of different rock units were miners. Mining had been of commercial interest since at least the days of the Romans, but it wasn't until the 1500s and 1600s that these efforts produced an interest in local rock relationships. By noting the relationships of different rock units, Nicolaus Steno in 1669 described two basic geologic principles. The first stated that sedimentary rocks are laid down in a horizontal manner, and the second stated that younger rock units were deposited on top of older rock units. To envision this latter principle, think of the layers of paint on a wall. The oldest layer was put on first and is at the bottom, while the newest layer is at the top. An additional concept was introduced by James Hutton in 1795, and later emphasized by Charles Lyell in the early 1800s. This was the idea that natural geologic processes were uniform in frequency and magnitude throughout time, an idea known as the principle of uniformitarianism. Steno's principles allowed workers in the 1600s and early 1700s to begin to recognize rock successions. However, because rocks were locally described by the color, texture, or even smell, comparisons between rock sequences of different areas were often not possible. Fossils provided the opportunity for workers to correlate geographically distinct areas. This contribution was possible because fossils are found over wide regions of the earth's crust.

For the next major contribution to the geologic timescale we turn to William Smith, a surveyor, canal builder, and amateur geologist in England. In 1815 Smith produced a geologic map of

England in which he successfully demonstrated the validity of the principle of faunal succession. This principle simply stated that fossils are found in rocks in a very definite order. This principle led others who followed to use fossils to define increments within a relative timescale.

Arthur Holmes (1890–1965) was the first to combine radiometric ages with geologic formations in order to create a geologic timescale. His book, *The Age of the Earth,* written when he was only 22, had a major impact on those interested in geochronology. For his pioneering scale, Holmes carefully plotted four radiometric dates, one in the Eocene and three in the Paleozoic, from radiogenic helium and lead in uranium minerals, against estimates of the accumulated maximum thickness of Phanerozoic sediments. If we ignore sizable error margins, the base of the Cambrian interpolates at 600 mya, curiously close to modern estimates. The new approach was a major improvement over a previous "hourglass" method that tried to estimate maximum thickness of strata per period to determine their relative duration, but had no way of estimating rates of sedimentation independently. In 1960, Holmes compiled a revised version of the age-versus-thickness scale. Compared with the initial 1913 scale, the projected durations of the Jurassic and Permian are more or less doubled, the Triassic and Carboniferous are extended about 50%, and the Cambrian gains 20 million years at the expense of the Ordovician.

W. B. Harland and E. H. Francis as part of a Phanerozoic timescale symposium coordinated a systematic, numbered radiometric database with critical evaluations. Items in The Phanerozoic Time-Scale: A Symposium, were listed in the order as received by the editors. Supplements of items were assembled by the Geological Society's Phanerozoic Time-Scale Sub-Committee from publications omitted from the previous volume or published between 1964 and 1968, and items relating specifically to the Pleistocene were provided primarily by N. J. Shackleton. The compilation of these additional items with critical evaluations was included in *The Phanerozoic Time-Scale: A Supplement* published in 1971 by Harland and Francis. In 1978, R. L. Armstrong published a reevaluation and continuation of The Phanerozoic Time-Scale database. This publication did not include abstracting and critical commentary. These catalogs of items and of Armstrong's continuation of items were denoted "PTS" and "A," respectively, in later publications.

In 1976, the Subcommission on Geochronology recommended an intercalibrated set of decay constants and isotopic abundances for the U-Th-Pb, Rb-Sr, and K-Ar systems with the uranium decay constants by Jaffey et al. in 1971 as the mainstay for the standard set. This new set of decay constants necessitated systematic upward or downward revisions of previous radiometric ages by 1%–2%.

In *A Geological Time Scale,* Harland et al. standardized the Mesozoic–Paleozoic portion of the previous PTS-A series to the new decay constants and included a few additional ages. Simultaneously, in 1982 G. S. Odin supervised a major compilation and critical review of 251 radiometric dating studies as Part II of *Numerical Dating in Stratigraphy*. This "NDS" compilation also reevaluated many of the dates included in the previous "PTS–A" series. A volume of papers on The Chronology of the Geological Record from a 1982 symposium included reassessments of the combined PTS–NDS database with additional data for different time intervals. After applying rigorous selection criteria to the PTS–A and NDS databases and incorporating many additional studies (mainly between 1981 and 1988) in a statistical evaluation, Harland and coworkers presented *A Geological Time Scale 1989*.

The statistical method of timescale building employed by *GTS82* and refined by *GTS89* derived from the marriage of the chronogram concept with the chron concept, both of which represented an original path to a more reproducible and objective scale. Having created a high-temperature radiometric age data set, the chronogram method was applied that minimizes the misfit of stratigraphically inconsistent radiometric age dates around trial boundary ages to arrive at an estimated age of stage boundaries. From the error functions, a set of age/stage plots was created (Appendix 4 in *GTS89*) that depicts the best age estimates for Paleozoic, Mesozoic, and Cenozoic stage boundaries. Because of wide errors, particularly in Paleozoic and Mesozoic dates, *GTS89* plotted the chronogram ages for stage boundaries against the same stages with relative duration scaled proportionally to their component chrons. For convenience, chrons were equated with biostratigraphic zones. The chron concept in *GTS89* implied equal duration of zones in prominent biozonal schemes, such as a conodont scheme for the Devonian.

The Bureau de Récherches Géologiques et Minières and the Société Géologique de France published a stratigraphic scale and timescale compiled by Odin and Odin. Of more than 90 Phanerozoic stage boundaries, 20 lacked adequate radiometric constraints, the majority of which were in the Paleozoic.

The International Stratigraphic Chart is an important document for stratigraphic nomenclature (including Precambrian), and included a summary of age estimates for stratigraphic boundaries.

During the 1990s, a series of developments in integrated stratigraphy and isotopic methodology enabled relative and linear geochronology at unprecedented high resolution. Magnetostratigraphy provided correlation of biostratigraphic datums to marine magnetic anomalies for the Late Jurassic through Cenozoic. Argon–argon dating of sanidine crystals and new techniques of uranium–lead dating of individual zircon crystals yielded ages for sediment-hosted volcanic ashes with analytical precessions less than 1%. Comparison of volcanic-derived ages to those obtained from glauconite grains yielded systematically younger ages, thereby removing a former method of obtaining direct ages on stratigraphic levels. Pelagic sediments record features from the regular climate oscillations produced by changes in the earth's orbit, and recognition of these "Milankovich" cycles allowed precise tuning of the associated stratigraphy to astronomical constants.

Aspects of the *GTS89* compilation began a trend in which different portions of the geologic timescale were calibrated by different methods. The Paleozoic and early Mesozoic portions continued to be dominated by refinements of integrating biostratigraphy with radiometric tie points, whereas the Late Mesozoic and Cenozoic also utilized oceanic magnetic anomaly patterns and astronomical tuning. A listing of the radiometric dates and discussion of specific methods employed in building *GTS2004* can be found in Gradstein, Ogg, and Smith's *A Geologic Time Scale 2004*.

Calibration

Because the timescale is the main tool of the geological trade, insight on its construction, strengths, and limitations greatly enhances its function and its utility. According to Gradstein, all scientists should understand how the evolving timescales are constructed and calibrated, rather than merely using the numbers in them.

The calibration to linear time of the succession of events recorded in the rock record has three components: (1) The international stratigraphic divisions and their correlation in the global rock record, (2) the means of measuring linear time or elapsed durations from the rock record, and (3) the methods of effectively joining the two scales.

For convenience in international communication, the rock record of Earth's history is subdivided into a chronostratigraphic scale of standardized global stratigraphic units, such as "Paleogene," "Eocene," "*Morozovella velascoensis* planktic foraminifera zone," or "polarity Chron C24r." Unlike the continuous ticking clock of the chronometric scale (measured in years before the present), the chronostratigraphic scale is based on relative time units in which global reference points at boundary stratotypes define the limits of the main formalized units, such as Neogene. The chronostratigraphic scale is an agreed convention, whereas its calibration to linear time is a matter for discovery or estimation. By contrast, Precambrian stratigraphy is formally classified chronometrically; that is, the base of each Precambrian eon, era, and period is assigned a numerical age.

Continual improvement in data coverage, methodology, and standardization of chronostratigraphic units implies that no geologic timescale can be final. *A Geologic Time Scale 2004* (*GTS2004*) provides an overview of the status of the geological timescale and is the successor to *GTS1989*.

Since 1989, there have been several mayor developments. Stratigraphic standardization through the work of the International Commission on Stratigraphy (ICS) has greatly refined the international chronostratigraphic scale. In some cases, traditional European-based geological stages have been replaced with new subdivisions that allow global correlation. New or enhanced methods of extracting linear time from the rock record have enabled high-precision age assignments. An abundance of high-resolution radiometric dates has been generated and has led to improved age assignments of key geologic stage boundaries. Global geochemical variations, Milankovitch climate cycles, and magnetic reversals have become important calibration tools. Statistical techniques of extrapolating ages and associated uncertainties to stratigraphic events have evolved to meet the challenge of more accurate age dates and more precise zonal assignments. Fossil event databases with multiple stratigraphic sections through the globe can be integrated into composite standards.

The compilation of *GTS2004* has involved a large number of specialists, including contributions by past and present chairs of different subcommissions of ICS, geochemists working with radiometric and stable isotopes, stratigraphers using diverse tools from traditional fossils to astronomical cycles to database programming, and geomathematicians. The set of chronostratigraphic units (stages, eras) and their computed ages, which constitute the main framework for *A Geologic Time Scale 2004,* are summarized in the chart available online from the ICS.

Geology

Geology is the scientific study of planet Earth and its history, through 4,600 million years to the present. This natural science is traditionally divided into two branches: physical geology and historical geology. Physical geology focuses on physical structure, materials, and geological processes of the earth. Historical geology examines the origin of our planet and life, and all the climatic, geographic, oceanographic, and biological events that have taken place across geological time. This dual division is rather arbitrary, therefore both points of view (physical and historical) are found currently integrated within the framework of plate tectonics, the current paradigm of geological science.

Physical Geology

Physical geology includes such disciplines as: geophysics (applies principles of physics to the study of the earth); geochemistry (the study of the chemical characteristics of minerals and rocks); mineralogy and petrology (the study of the origin, properties, structure, and classification of minerals and rocks, respectively); hydrogeology (the study of the origin, occurrence, and movement of water masses); structural geology (the study of the deformational history of rocks and regions and of the forces responsible); geomorphology (the study of the origin and modification of landforms); volcanology (the study of volcanoes and magma formation processes); sedimentology (the study of sedimentary rocks and the processes by which they were formed); and engineering geology (the study of the interactions of the earth's crust with human-made structures such as tunnels and mines).

Some areas of specialization for professional geologists related to physical geology include exploration and extraction of natural resources (mineral deposits, coal, oil, etc.), prediction and evaluation of geological hazards (landslides, earthquakes, volcanic eruptions, or meteoritic impacts), evaluation of the stability of construction sites, the search for supplies of clean water, and analysis of environmental problems such as soil and coastal erosion.

Historical Geology

A consubstantial part of geology is the study of how Earth's materials and continents, surface environments, processes, and organisms have changed over geological time. Processes, fossils, and geological events are recorded in rocks. Thus the main objective of historical geology is the analysis of the geological record in order to reconstitute and understand the earth's history. Historical geology is based on paleontology (the study of life in the past from the fossil record, including evolutionary relationships, and its applications in environmental reconstructions and in the relative dating of rocks); stratigraphy (the study of stratified rocks in terms of mode of origin, original succession, relative dating, and geologic history), and paleogeography (the reconstruction of the ancient geography of the earth's surface). Other important disciplines closely related to historical geology are: paleoclimatology (the application of geological science to determine past climatic conditions) and paleoceanography (the reconstruction of the history of the oceans, with regard to circulation, chemistry, or patterns of sedimentation).

When geologists come to interpret the earth's history, they rely on two complementary types of dating of rocks: relative dating and absolute dating. Relative dating places historical events in their correct temporal order, and absolute dating provides a numerical age for a rock and establishes how many years ago a geological event took place.

Relative Dating

The relative ages of rocks and events in geologic sequences can be established by interpreting the fossil record and utilizing several basic principles in stratigraphy. The four most important are: the principle of original horizontality (sedimentary rocks are formed in essentially horizontal beds named strata; nonhorizontal strata have been disturbed after lithification), the principle of superposition (in any undisturbed stratigraphic sequence, older strata are buried beneath younger strata), the principle of intersection (when a fault or igneous intrusion cuts across a formation of sedimentary rocks, the fault or the intrusion is younger than these strata), and the principle of inclusions (the inclusion of a rocky body in a sequence of strata is older than the sedimentary rocks that contain it). Since the 19th century, the application of these rules to establish the relative ages of rocks contributed to developing the standard geological column in geological sites undisturbed or minimally disturbed, such as the Zumaya stratigraphic section in Spain.

Geologists soon understood that to develop a global geological timescale, a comparison of rocks of similar age located in different regions or continents was required. This process is known in stratigraphy as "correlation." Correlation involves matching up rock layers of similar age that are in different regions. When conditions of exposure are good, the litho-correlation across short distances can be done by applying the principle of lateral continuity (sediments are deposited forming strata over a large area in a continuous sheet). When correlation involves a long distance (even

between two different continents), geologists depend on the fossil remains of ancient organisms. In this case the bio-correlation is carried out using the principle of faunal succession (in a stratigraphic sequence, fossil species succeed one another in a definite and determinable order, so any time period can be recognized by its fossil content).

Fossil species appear and disappear throughout the fossil record as a consequence of the evolution (speciation and extinction) of species. As each fossil species lived during a specific interval of geological time, its presence (or sometimes absence) may be used to provide a relative age for the strata in which it is found. Each fossil species also lived at the same time in a more or less extensive geographical region. For this reason, paleontologists can use fossils to establish a bio-correlation of strata among different localities, where fossils of one species or of a species assemblage were present.

Correlation based on fossils is the focus of biostratigraphy, a discipline that deals with the distribution of fossils in the stratigraphic record, and the organization of strata into correlatable units (biozones) on the basis of the fossils they contain. Most species lived for tens of millions of years before they became extinct or evolved into new species. Nevertheless, some species lived for only hundreds of thousands of years or a few million years. If they were limited to a short period of time, had a wide geographic distribution, and are abundant in the fossil record, these species are considered "index fossils." Index fossils provide a precise means for estimating the relative age of sedimentary rock, and for correlating biozones. For example, many species of trilobites, ammonites, or foraminifera are ideal for biostratigraphy in marine series, and micro-mammals, grains of pollen, and spores are good index fossils for continental deposits.

Absolute Dating

The discovery of radioactivity and the development of the mass spectrometer in the 20th century permitted many radioactive elements to be used as geologic clocks. These techniques are based on the natural decay of radioactive elements (unstable isotopes) that cause the radioactive parent elements to decay to stable daughter elements.

Through the radioactive decay of isotopes in rock, exotic daughter elements are introduced over time. By measuring the concentration of the stable end products of decay, coupled with knowledge of the half-life and initial concentration of the decaying elements, the age of a rock can be calculated. This technique is known as radiometric dating, a powerful tool for reconstructing the earth's history.

Potassium-40, for example, decays into argon-40 after a half-life of 1.25 billion years, so that after 1.25 billion years half of the potassium-40 in a rock will have become argon-40. This means that if a rock sample contained equal amounts of potassium-40 and argon-40, it would be 1.25 billion years old. Other isotopes used in radiometric dating are: uranium-235, uranium-238, thorium-232, and rubidium-87.

Relative Versus Absolute Dating

Relative dating provides a relative timescale formed by bio- and chronostratigraphical units. Absolute dating provides an absolute timescale composed of geochronological units. But how are both scales correlated and integrated in the geological timescale if fossils occur in sedimentary rocks, and most minerals that contain radioactive isotopes are in igneous rocks?

The simplest method to correlate both scales is the radiometric dating of volcanic ash or of oceanic basaltic layers that are interbedded between sedimentary rocks. The age of the volcanic rock is younger than the underlying sedimentary rocks and older than the overlying sedimentary rocks. If these sedimentary rocks contain fossils, they are very relevant since they can be correlated with the biozones defined in this area. Thus, rocks whose ages have been determined by absolute dating can be incorporated into a succession of strata determined by relative dating. Then geologists can use correlations to infer the ages of rocks and fossils that cannot be directly dated. In fact, the combined absolute/relative timescale is always being revised in order to produce an even more precise picture of Earth's history.

A Brief History of the Earth

From the modern methods of radiometric age dating, we know that the earth is around 4.6 billion years old. Historical geologists divide all this geological time into three major divisions (eons):

Archaean, Proterozoic, and Phanerozoic, although a fourth pregeologic eon is considered: Hadean. All of them are made up of eras that usually ended with profound changes in the disposition of the earth's continents and oceans, and are characterized by the emergence of new forms of life or by the disappearance of ancient ones.

Hadean Eon (4550–3900 Million Years Ago)

The Hadean eon is the geologic time extending from the birth of the solar system and the earth's formation 4,600–4,550 million years ago, to the formation of the oldest rocks 3,900–3,800 million years ago (mya). The Hadean is the first eon in the earth's History, but very little geological record was preserved because the earth's surface was molten.

The solar system's planets, including the earth, were formed by accretion from a cloud of gas and dust known as solar nebula. Grains in orbit around the central primitive sun (protoplanetary disk) began to join, collecting in bodies called planetesimals. In a few million years, several large planets grew through low-velocity collisions between nearby planetesimals. The planets and satellites formed in the inner solar system—Earth, Mars, and Venus—were composed mainly of materials with high melting points, such as silicates and metals (iron and nickel).

Since the Hadean lacks any official status, this eon has been arbitrarily subdivided in three informal periods, taking into account the primitive geological history of the moon: Cryptic (4,550–4,500 mya), Ryderian (4,500–4,100 mya), and Nectarian (4,100–3,900 mya). The first period includes the accretion time of Earth from the solar disk, the big whack event, and the formation of the moon. The big whack is a hypothetical event that occurred roughly 4,530 mya in which a Mars-sized body, usually called Theia, impacted the proto-Earth at an oblique angle. The giant impact destroyed Theia, ejecting into space most of its mass together with a significant portion of the earth's silicate mantle. A ring of debris began to orbit near the earth's equator, coalescing into the moon about 100 years after the huge impact. The Ryderian era includes the progressive cooling of the earth (and the moon) and the process of differentiation of the earth's core, mantle, and protocrust, when the earth acquired a primitive inner structure.

A great number of asteroidal and cometary objects remained among the newborn planets, starting a well-known period called the Late Heavy Bombardment (LHB) during the Nectarian era. The LHB happened about 4,100–3,800 mya, resulting in a large number of impact craters on the earth as well as on the rest of the planets and satellites in the solar system. This cataclysm period created an enormous amount of heat, completely melting the earth and allowing its materials to separate definitively into three main layers: iron core, silicate mantle, and thin outer crust. This intensive bombardment probably destroyed the primitive earth's protocrust, retaining only individual zircon crystals that were redeposited in most modern sediments. The oldest known zircons were radiometrically dated to about 4,400 million years and are found in the Acasta Gneiss in western Canada. The study of some of these zircons suggests that there was liquid water at that period, indicating that primitive atmosphere and oceans must have existed then. The rock vapor might condense around the young Earth, resulting in a dense atmosphere of carbon dioxide, water, methane, nitrogen, and hydrogen.

Archean Eon (3,900–2,500 Million Years Ago)

The Archean eon is the geologic time that extends from the formation of the oldest rocks 3,900–3,800 mya to 2,500 mya. It is formally subdivided into four eras: Eoarchaean (3,900–3,600 mya), Paleoarchean (3,600–3,200 mya), Mesoarchean (3,200–2,800 ma) and Neoarchean (2,800–2,500 mya). A significant event occurred at the beginning of the Archaean eon: the origin of life, in a scenario with an atmosphere composed mostly of carbon dioxide.

The oldest known rocks on Earth are found in the Issua Greenstone Belt (southwestern Greenland) and include well-preserved volcanic, metamorphic, and sedimentary rocks dated at 3,800–3,700 million years. Archean volcanic activity was probably considerably more intensive than it is today, and plate tectonics were surely very active because the inner earth was much hotter at that time. A greater rate of recycling of crustal material should have occurred then, preventing the formation of continents. For this reason, only some Archean rocks survive, including metamorphized igneous rocks, such as granites, peridotites, and unusual ultramafic mantle-derived volcanic rocks called komatiites. Archean rocks also include stromatolites (the oldest fossil traces of prokaryotic organisms), and hard metamorphized deepwater sediments.

Only when the mantle cooled and convection slowed down could the tectonic activity slow down. Small protocontinents (*cratons*) were the norm during the Archean eon. Several Archean cratons have been identified, including a hypothetical first continent now called Vaalbara. According to radiometric dating, the Vaalbara continent existed at least 3,300 mya during the Paleoarchean era. This continent collected the two only known Eoarchean cratons: Kaapvaal craton (South Africa) and Pilbara craton (Western Australia). Other continents were probably formed 3,000 mya in the Mesoarchean era, grouping small cratons of present western Australia, eastern India, eastern Antarctica, and southeastern Africa. It is now called the Ur continent.

During the Neoarchean era, 2,700 mya, the earliest known supercontinent, called Kenorland, was born. It formed as result of a series of events of accretion, comprising several cratons: Laurentia (including Canada and Greenland), Baltica (including Scandinavia and the Baltic area), Yilgarn (Western Australia), and Kalahari (Botswana, South Africa, and Namibia).

Proterozoic Eon (2,500–542 Million Years Ago)

The Proterozoic eon began 2,500 mya, and ended with the disappearance of the complex Ediacaran biota 542 mya. The geological record of the Proterozoic is much better known than that of the Archean, since Proterozoic rocks are less metamorphized and are more abundant. Many Proterozoic sedimentary rocks were deposited in extensive shallow epicontinental seas, and their study suggests that Proterozoic plate tectonics were both massive and rapid.

The Proterozoic eon has been formally subdivided into three eras: Paleoproterozoic (2,500–1,600 mya), Mesoproterozoic (1,600–1,000 mya), and Neoproterozoic (1,000–542 mya). Both the start and the end of the Proterozoic were marked by widespread glaciation: the Huronian and Varangian glaciations, respectively.

Paleoproterozoic Era (2,500–1,600 Million Years Ago)

The Huronian glaciation began 2,400 mya and lasted until 2,100 mya. It was one of the most severe ice ages, and it is possible that the earth's surface was entirely covered by ice. It is perhaps related to the decrease of atmospheric carbon dioxide, consumed and captured by photosynthetic microorganisms, and the virtual disappearance of the greenhouse gas methane due to chemical oxidation.

The neoarchaic Kenorland supercontinent began to break up at the start of the Siderian period (2,500–2,300 mya) when two Baltic fragments, the Kola and Karelia cratons (today in Russia), began to drift apart. During the Rhyacian (2,300–2,050 mya), several continents were created out of Kenorland when it broke up: Arctica (including today's Canada and Siberia), Atlantica (including today's eastern South America and western Africa), and Baltica (northern Europe). Cyanobacteria developed in the Siderian and Rhyacian seas, producing a great quantity of photosynthetic oxygen that resulted in a large increase of this gas in the atmosphere. The combination of oxygen with the iron dissolved in the oceans formed a distinctive Archaic–Paleoproterozoic type of rock called banded iron formations (BIFs) that are composed of iron oxides like magnetite and hematite.

The atmosphere became oxygen rich during the Orosirian period (2,050–1,800 mya) with a progressive decrease in iron dissolved in the ocean. The formation of BIFs ceased, but the deposition of the so-called red beds began. These rocks are tinged with hematite, indicating an increase in atmospheric oxygen. The progressive accumulation of oxygen in the atmosphere might have caused the extinction of numerous groups of anaerobic bacteria, the only type of life that existed up to that time. This event has sometimes been called the oxygen catastrophe. From the point of view of plate tectonics, collisions between cratons were common during this period, forming multiple orogens worldwide that were the prelude to the formation of the supercontinent Columbia.

The last period of the Paleoproterozoic, the Statherian (1,800–1,600 mya), was characterized by its tectonic stability. At the beginning of the Statherian, the supercontinent Columbia was formed and lasted from approximately 1,800 to 1,500 mya. It consisted of almost all of Earth's continents: Laurentia (proto-North America), Nena (Arctica, Baltica, and eastern Antarctica), Atlantica (Amazonia and western Africa), Ur (Australia, India, and northern Antarctica), and possibly northern China and Kalahari (southern Africa). At the beginning of the Statherian a new type of cell appeared, eukaryotic cells, that experienced great evolutionary exits in later periods of mass extinction.

Mesoproterozoic Era (1,600–1,000 Million Years Ago)

The Mesoproterozoic era began with the breakup of Columbia and ended with the formation of a new supercontinent: Rodinia. By about the Mesoproterozoic era, 80% of the earth's continental crust had been formed. Columbia began to fragment at the start of the Calymnian period (1,600–1,400 mya), forming several continents that drifted apart, including Laurentia, Nena, Australia-Antarctica, Amazonia, Sahara (northern Africa), Congo (west-central Africa), Kalahari (southern Africa), and Sao Francisco (southeastern South America).

Rodinia began forming in the Ectasian period (1,400–1,200 mya) and finished assembling during the Stenian period (1200–1000 mya). The Laurentian continent was the core of Rodinia, and was sandwiched between two large blocks: East Gondwana (the original continent of Ur) and West Gondwana (the original continent of Atlantica). Moreover, Baltica and Siberia were nearby, to the southeast and northeast of Laurentia, respectively. Rodinia was surrounded at that time by a great superocean called Mirovia, in which the first cells with sexual reproduction appeared.

Neoproterozoic Era (1,000–542 Million Years Ago)

The Neoproterozoic era was a time of complex continental drift that followed the breakup of Rodinia. The breakup of this supercontinent started in the Tonian period (1,000–850 mya) and continued through the Cryogenian period (850–630 mya). In the first phase, 800 mya, Rodinia split into two large segments. The lands of East Gondwana and Congo (the Proto-Gondwana continent) moved north while rotating counterclockwise, beginning the formation of the Panthalassic superocean. The great block composed of Laurentia, Siberia, Baltica, South China, and West Gondwana (the Proto-Laurasia continent) drifted southward, rotating clockwise. The Panafrican Ocean formed between these macrocontinents.

Recent studies indicate that at least seven independent continents must have existed around 750 mya: Laurentia-Baltica-West Gondwana, North China, Siberia, Australia-East Antarctica, South China, Malani (India, Iran, Arabia, and Madagascar), and Congo-Kalahari. During the Ediacaran period (630–542 mya), most of the earth's large continents came together again in the southern hemisphere. They formed the Pannotia supercontinent, which was short lived since it lasted only about 60 million years.

The Cryogenian period is characterized by the massive Varanginian glaciations that are represented by worldwide tillite deposits, suggesting that the earth suffered the most severe ice age of its history with glaciers extending as far as the equator. It is believed that all the planetary oceans were deeply frozen, a phenomenon known as Snowball Earth. Finally, the last Neoproterozoic period, the Ediacaran, is unusual because it contains strange soft bodied fossils known as Ediacaran biota. The severe Neoproterozoic glaciations caused profound changes in oxygen levels and ocean chemistry, which could explain why life developed intensively during the Ediacaran and later during the Cambrian.

Phanerozoic Eon (542 Million Years Ago to the Present)

The Phanerozoic eon left a rich fossil record, starting with the Cambrian explosion about 540 mya. It is formally subdivided into three eras: Paleozoic (542–251 mya), Mesozoic (251–65 mya), and Cenozoic (65 mya to the present).

Earth seems to have gone through alternating icehouse (with ice caps) and greenhouse (without ice caps) phases during the Phanerozoic, perhaps partly controlled by how the continents and oceans were distributed. At least three icehouse phases are known: Late Ordovician–Silurian (about 460–416 mya), Late Carboniferous–Permian (about 318–251 mya), and the Oligocene–Neogene period (34 mya to the present). Throughout the Phanerozoic new continents and oceans appear and disappear, assembling and separating until reaching their present locations. This is a complex history, and the reader is invited to visit the Paleomap project's Web page where several full-color paleogeographic maps are available that show the changing distribution of lands and seas, as well as the various continental and oceanic plates that developed in the earth's recent history.

Paleozoic Era (542–251 Million Years Ago)

The Paleozoic era covers the geological time from the first occurrence of an abundant fossil record (Cambrian Explosion) to the greatest mass extinction event in the earth's history: the Permian–Triassic boundary event. The Cambrian Explosion was the greatest evolutionary radiation in the earth's history, bringing forth nearly all the major groups or phyla of animals, including the trilobites. The Paleozoic began with the breakup of the Pannotia supercontinent and ended with the formation the last known supercontinent, Pangea.

Pannotia started to break up at the beginning of the Cambrian period (542–488 mya) and formed four continents: Laurentia (North America), Baltica (Northern Europe), Siberia, and Gondwana. The three first drifted toward the north and Gondwana drifted toward the south, with most of the land staying in equatorial latitudes. The Panthalassic superocean covered most the northern hemisphere, and two new minor oceans began to form: Proto-Tethys and Iapetus. Proto-Tethys formed between the proto-Laurasian continents (Laurentia, Baltica, and Siberia) and Gondwana. Iapetus formed between Baltica and Laurentia. The Cambrian oceans seem to have been broad and shallow, causing a climate significantly warmer than that of the preceding periods dominated by ice ages.

At the start of the Ordovician period (488–443 mya), Gondwana began to drift toward the South Pole. The Ordovician climate was very warm, and Laurentia, Baltica, and Gondwana were widely covered by warm shallow seas, allowing the development of shelled organisms and the deposition of great amounts of biogenic limestone. While the Panthalassic superocean still covered most of the northern hemisphere, another ocean was born, the Paleo-Tethys, which was taking over territory at the expense of ancient Proto-Tethys. The new Rheic Ocean was the result of the formation of the Avalonia microcontinent (composed mainly of Newfoundland and England) that had broken off from Gondwana and drifted toward Baltica. That ocean was gaining territory at the expense of the old Iapetus Ocean. By the end of the Ordovician, Gondwana was approaching the South Pole and was largely glaciated. The extensive glaciation of Gondwana and the subsequent fall of the sea level may have triggered the Late Ordovician mass extinction event between 447–444 mya, in which the 85% of species died off.

The icecaps of the Silurian period (443–416 mya) were less extensive than those of the Late Ordovician, and the melting of the Silurian icecaps and glaciers contributed to a rise in the sea level. During this period, continents drifted near the equator and the earth's climate entered a long greenhouse phase with warm shallow seas covering much of the equatorial landmasses. Coral reefs expanded, and land plants began to colonize the barren continents. Baltica and Laurentia started to collide, completely closing off the Iapetus Ocean and forming the Euramerica macrocontinent. Such collisions folded the sediments deposited in the previous Iapetus basin, forming the Caledonian orogen (Appalachian Mountains, the Anti-Atlas in Morocco, and the Caledonian Mountains in Great Britain and Scandinavia). At that time, the Rheic and Paleo-Tethys oceans occupied the area between Euramerica and Gondwana, and between Siberia and Gondwana, respectively. During the Silurian a new ocean was formed, the Ural Ocean, located between Siberia and Baltica.

The Devonian period (416–359 mya) was a time of great tectonic activity as the continents drew closer together. The Ural Ocean disappeared toward the end of the Devonian when Siberia collided with the Baltica coast of Euramerica, forming the Ural Mountains and the Laurussia macrocontinent, also called the Old Red Continent. Sea levels were high worldwide during the Devonian, with broad areas of continents widely submerged under shallow seas where tropical reef organisms were plentiful. The deep waters of the giant Panthalassic superocean covered most of the earth, Paleo-Tethys continued spreading, and other minor oceans the Rheic Ocean began to close off. The Devonian ended with a major mass extinction event that affected up to 82% of all species, probably caused by several meteorite impacts like those forming the 120-kilometer–diameter Woodleigh crater (Australia).

The well-known Pangea supercontinent began to form in the Carboniferous period (359–299 mya). Laurussia and Gondwana collided during this period, definitively closing the Rheic Ocean. The collision occurred along the eastern coast of North America (where the Alleghenian orogen was formed) and the northwestern coast of South America, Africa, and South Europe (where the Hercinian orogen emerged). Finally, North China collided with Siberia at the end of the Carboniferous, closing off another old ocean, the Proto-Tethys. Most the continents were grouped together toward the end of the Carboniferous, although South China was still separated from Laurussia by the Paleo-Tethys Ocean. The Carboniferous was a period of active mountain-building. There was also a drop in south polar temperatures, glaciating the southern portion of Gondwana. Nevertheless, the tropical latitudes were warm and humid, allowing for the development of extensive forests and swamps.

Except for the South China continent, all of Earth's major land masses were grouped together as Pangea in the Permian period (299–251 mya); Pangea reached from the equator toward both poles. This affected ocean currents in the Panthalassic superocean and the Paleo-Tethys, which was located between the Asian part of Laurussia and Gondwana. At the beginning of the Permian, a rift started to open from the north of Gondwana to form a new ocean: the Tethys Ocean. The Permian ended with the most extensive mass extinction event in geological history: the Permian–Triassic extinction event, affecting more than 90% of species. The Late Permian glaciations, Siberian Traps volcanism, severe drop in sea levels, and even several large meteorite impacts, among other causes, have been proposed to explain the massive extinction.

Mesozoic Era (251–65 Million Years Ago)

The Mesozoic era spans geological time from the Permian–Triassic boundary event 251 mya to the Cretaceous–Tertiary boundary event 65 mya. It was an era of intensive tectonic, climatic, and evolutionary activity.

During the Triassic period (251–199 mya), almost all of the earth's landmasses had collected into a single supercontinent, Pangea, that was surrounded by the Panthalassic superocean. The recently formed Tethys Ocean continued opening at the expense of the Paleo-Tethys. Since Pangea's large size limited the moderating effect of the oceans, the Triassic climate became very hot and dry, forming typical red bed sandstones and gypsum. This kind of terrestrial climate was suitable for reptiles. The Triassic ended with another major mass extinction episode that affected mainly marine environments. The cause of this extinction is uncertain, but global cooling or even meteorite impacts have been proposed. These extinctions allowed the dinosaurs to expand, initiating the Age of Dinosaurs that spanned the Jurassic (199–145 mya) and the Cretaceous (145–65 mya).

In the Early Jurassic, the oceanic crust of the Paleo-Tethys was completely subducted. This episode resulted in the collision of South China with Laurussia, initiating the Cimmerian orogeny that created mountain ranges as high as today's Himalayas. Pangea was shaped like a "C" at that time, curling around the Tethys Ocean with the concave area occupied by the Tethys Ocean. Both Pangea and Tethys were surrounded by the huge Panthalassic superocean. As in the Triassic, the Jurassic climate was warm; there is no evidence of glaciation since no continent was near either pole. During this period, Pangea began to break up into two major landmasses: Laurasia (North America and Eurasia) and Gondwana (South America, Africa, Australia, Antarctica, and India), which began the opening of the Central Atlantic Ocean. Toward the end of the Jurassic, the Panthalassic superocean converted into the current Pacific Ocean.

Pangea was definitively broken up during the Cretaceous into today's continents, although the continents had positions substantially different from today's. The progressive drift of the Laurasian and Gondwanan landmasses opened the western Tethys Ocean (today's Mediterranean Sea) and separated North America and South America, forming a continuous ocean current around the equator. The North Atlantic Ocean opened, separating Iberia from Newfoundland and England-Scandinavia from Greenland. The separation of South America and Africa formed the South Atlantic Ocean. Finally, the drift of India northward formed the Indian Ocean, which was gaining territory at the expense of eastern Tethys. This active rifting during the opening of the Atlantic Ocean raised mountain ranges (including the giant American Cordillera: the Rocky Mountains, the Sierra Madre, and the Andes Mountains) around the entire coastline of old Pangea. This intensive tectonic activity raised the sea level, forming broad shallow seas over North America (the Western Interior Seaway) and Europe. The Cretaceous climate was very warm, devoid of ice at the poles. The Cretaceous ended with the most recent major mass extinction event: the Cretaceous–Tertiary event 65 mya, affecting more than 75% of species. A meteorite impact that formed the approximately 180-kilometer-diameter Chicxulub crater (Yucatan, Mexico) appears to be its cause.

Cenozoic Era (65 Million Years Ago to the Present)

The Cenozoic era covers geological time from the Cretaceous–Tertiary mass extinction event to the present. During the Cenozoic, mammals evolved from a few small insectivores that had survived the Cretaceous–Tertiary extinction. The continents moved to their current positions, causing remarkable climatic and oceanographic changes.

During the Paleogene period (65–23 mya), the Laurasian and Gondwanan plates formed in the Cretaceous continued to split apart, with North America, Eurasia, South America, Africa, India, and Antarctica-Australia pulling away from each other. India continued its migration toward central Eurasia, and Africa also headed north toward western Eurasia, slowly closing the Tethys Ocean during the Paleocene epoch (65–56 mya). The rifting and splitting apart of Eurasia, Greenland, and North America increased hydrothermal and volcanic activity in the North Atlantic. This tectonic episode combined with the movement of the Indian plate northward, restricted the Tethys oceanic current, and helped to trigger the Paleocene–Eocene Thermal Maximum event 56 mya. During the Eocene epoch (56–34 mya), Antarctica and Australia began to split, leaving Antarctica isolated in its current location at the South Pole. Moreover, the Indian microcontinent collided with central Eurasia, folding the Himalayas upward and closing off the eastern Tethys Ocean. The western Tethys was converting into the present Mediterranean Sea, which was being progressively narrowed by the drift of Africa (including Arabia) toward Europe. The Alps started to rise in Europe as the African continent continued to push north into the Eurasian plate. All these continental movements culminated in the Oligocene epoch (34–23 mya). At that time Antarctica was isolated definitively, forming the circumantarctic ocean current and allowing a permanent ice cap to develop. A global cooling occurred during the Late Eocene and the Oligocene, causing a gradual major extinction episode.

The Neogene period covers the past 23 million years, during which modern birds and mammals, including humans, evolved. Continents continued to drift toward their current positions. During the Miocene epoch (23–5.3 mya), global mountain building continued to take place, raising the western American cordilleras, the Alps, and the Himalayas. Arabia, which became part of the Africa plate, collided with Eurasia, forming the Caucasus Mountains, separating the Indian Ocean and the Mediterranean Sea and closing off the remnants of the old Tethys. The rise of mountains in the western Mediterranean (the Betic Cordillera in southern Spain and the Rif Mountain in northern Morocco), combined with the global drop in sea level due to formation of Antarctica ice cap, caused what is known as the Messinian Salinity Crisis in the Mediterranean Sea approximately 6 mya. The Mediterranean Sea has dried up several times due to repeated closings of the old Straits of Gibraltar, thus forming enormous evaporative deposits throughout the Mediterranean. When the present Strait of Gibraltar eventually opened, the Atlantic would have poured a vast volume of water into the dry Mediterranean basin in a gigantic waterfall much more than 1,000 meters high and far more powerful than Niagara Falls. During the Pliocene epoch (5.3–1.8 mya), South America and North America joined, creating the Isthmus of Panama. This tectonic episode had major consequences for global temperatures: warm equatorial ocean currents were cut off and the climate became cooler and drier, resulting in the formation of the Arctic ice cap 2 mya. Both the Antarctic and the Arctic became much colder. During the Pleistocene epoch (1.8 million to 11,500 years ago), the modern continents were essentially at their present positions, initiating repeated glacial cycles. Four major glacial episodes have been identified (usually called Günz, Mindel, Riss, and Würm in the Alps; Nebraskan, Kansan, Illinoian, and Wisconsin in North America; Weichsel or Vistula, Saale, Elster, and Menapian in Northern Europe; and Devensian, Wolstonian, Anglian, and Beestonian in Britain), separated by interglacial episodes. The Holocene is the geological epoch that spans the last 11,500 years of the earth's history (from 9,500 BCE to the present), starting with the retreat of the Pleistocene glaciers. It was preceded by the Younger Dryas cold period, the final part of the Pleistocene, and it is characterized by global warming. The optimum climate of the Holocene has favored the flourishing of human civilizations.

Gerontology

Although research into human aging has been conducted sporadically for many years, it is only in the past several decades that it has gained enough momentum in the social sciences to become an established program of formal academic study—under the title "gerontology." Gerontology is the study of the processes of aging. The term comes from the Greek *γεροντοσ*, an old man and *λογοσ*, word, science, or study. A closely related term is *geriatrics,* the medical care of the elderly, coined by Ignatius Leo Nascher in 1909 from the Greek *γεροντοσ* and *γστροσ*, to cure.

Historical Perspective

The care of aging and injured individuals has a long record in the (pre)history of humankind. Some of the earliest evidence for such care comes from Neanderthal remains in Europe and the Middle East: for example the La Chappelle-aux-Saints fossils in France and those from Shanidar Cave in Iraq. In the case of the individual ("the Old Man") from La Chappelle-aux-Saints (the type specimen of *Homo neanderthalensis*), the bones indicate an individual who suffered from arthritis of the jaws, spine, and legs. It is unlikely that such an individual would have been capable of food procurement in a Paleolithic society of the type supposed for Neanderthals. The only way such an individual could survive to a relatively advanced age was through the care of others.

Ralph Solecki excavated the remains of an individual at Shanidar Cave in Iraq who appears to have survived the amputation of his right arm. He had been injured and possibly blinded in the left eye. He also showed a healed injury to the right parietal bone. Although he survived these injuries, he was eventually killed by a slab of falling limestone, while he stood upright. It is not unreasonable, therefore, to assume that there was some sort of care for such older (by Neanderthal standards) individuals who most likely would have been unable to forage for themselves.

In a brief history of gerontology, Joseph Freeman delineates nine periods in the "scientific" study of old age in the past 5,000 years; that is, since the dawn of recorded history. These periods include the Archaic period, which extended from the emergence of writing to the development of early civilizations. His second period lasted from the efflorescence of Mesopotamian, Biblical, and Egyptian cultures to the advent of Minoan and Greek civilizations and includes descriptions of the aged and codes of behavior toward them. The third period, the Greco-Roman, included Hippocrates and Aristotle among the Greeks and Galen and Cicero in Rome. During this period these individuals began to assemble a body of literature pertaining to the treatment of ailments that attend aging. The general belief was that "innate heat" from the heart began to diminish over time, and that this "cooling" led to aging.

During Freeman's Judeo-Arabic period, Moses Maimonides, Arnoldus de Villa Nova, and Avicenna described the differences between young and old and recommended regimens for older people, including less frequent blood-letting—only once per year for septuagenarians.

The period of European Emergence brought with it the first book specifically devoted to geriatrics: Gabrielle Zerbi's *Gerontocomia,* published in 1489. Roger Bacon argued reasonably in *De retardanis senectutis accedentibus, et de sensibus conservandis,* printed in Oxford in 1590 (300 years after Bacon's death) that if people were as zealous in their efforts to conserve health as to restore it, they would lead longer lives free of disease. Bacon recommended the use of magnifying glasses for older people with poor vision shortly before the appearance, in Italy, of vision-correcting eyeglasses.

A Renaissance publication in 1534, *The Castel of Healthe,* by Sir Thomas Elyot, advised the elderly to follow a prudent diet consisting of a number of small meals per day rather than a few large ones. Sir John Floyer wrote in *Medicina Gerocomica* that old age is the result of an imbalance of bodily humors, with a preponderance of cold and dry.

During the seventh period, Benjamin Franklin published translations of earlier works on senescence and expressed interest in the variety of ways with which to increase health and stave off old age. Shortly after Franklin's death, Christoph Wilhelm Hufeland published *The Art of Prolonging the Life of Man* in which he prescribed a *Makrobiotik* approach.

In 1804, Sir John Sinclair translated classical works, reviewed statistics, and summarized much of the previous work on aging. Later, Sir Anthony Carlisle published *Essay on the Disorders of Old Age* and advised young people to take care of themselves early in life if they wished to secure longevity. Carl Canstatt wrote on general theories of aging in 1839 and hypothesized that the death of cells led to irreplaceable tissue death. In Paris, Jean-Martin Charcot lectured that the diseases that accompany aging have a latency period, which, it appears, some such as cancers do. The primary concern still was to look upon senescence as pathology, rather than as a normal continuance of the lifelong aging process, but by the 1890s C. A. Stephens opened a laboratory in Maine for the study of old age and began a magazine called *Long Life.*

Although quite a bit of data on biological and environmental factors in longevity were generated during the 1940s, advances in gerontology have accelerated since 1950 because of advances in medicine, emphasizing physical and mental health in later years. Demographic and economic studies have been concerned with the effects changes in the age structure would have on the social and financial sectors. For example, what changes would occur in taxation structures should the mandatory retirement age change from 65 to 70 or to 60 years?

Recent Theories and Research

A major impetus to aging studies was disengagement theory introduced by Elaine Cumming and W. E. Henry in *Growing Old: The Process of Disengagement,* based upon the Kansas City Study of Adult Life. Previously, much of the literature on aging was material gathered from research on other topics, or it was concerned with cataloging characteristics of the aged. Cumming and Henry proposed that elderly people around the world perform mutual disengagement from their societies. Disengagement was supposed to be an inevitable developmental event in the life cycle, although its start and pattern might vary from culture to culture. This was thought to lead to (or at least correlate with) passivity in later life.

However, David L. Gutmann's study of the highland Druze demonstrated that disengagement is not inevitable, and passivity does not necessarily accompany it. Gutmann felt that in traditional folk societies with strong religious orientations, older people's passivity may be a central and necessary component of their *new* engagement with social roles and traditions associated with their new status. What is taken for passivity in modern societies is a move toward religious engagement—mastery of the supernatural realm—in traditional societies. According to Gutmann, what Cumming and Henry found in American society is not universal, but is an "artifact of secular society" that rejects a normative order dependent upon older persons' traditional, moral roles after passing the "parental and productive life periods." Gutmann argues that this shift to Passive and Magical Mastery does not necessarily lead to disengagement and death, but to social rebirth through the religious role that turns destructive passivity in older persons into vehicles of social power.

Activity theory is an alternative to disengagement based upon the observation that some people not only do not *choose* to disengage, but also that they *do not* disengage. Activity theory, or "reengagement," like disengagement theory, is concerned with the relationship between levels of activity and psychological health in the last trimester of life. Activity theory proposes that there may be a natural tendency for older people to associate with other persons and to be active in community affairs. Contemporary retirement practices block this natural inclination and may lead to poor adjustment. By allowing continued engagement in community activities, or by prompting reengagement in society, older persons may maintain (or regain) psychological health. Robert Havighurst noted that for the three dimensions of aging studied by the Kansas City group, activity, satisfaction, and personality, it is personality that is the key factor in patterns of aging and life satisfaction. He concluded that both activity and disengagement theories are unsatisfactory, as they do not deal with personality differences within the older population.

Continuity theorists, such as Robert Atchley, feel that a simple relationship between activity levels and psychological health is insufficient to explain social aging. Continuity theorists propose that one's levels of engagement and psychological well-being are the results of lifelong patterns of activity or inactivity and psychological health or ill health. Linda George argues that continuity theory has value not only for historical interest, but because it accounts for individual differences—something that previous theories did not. George tested the impact of personality and social status variables upon levels of activity and psychological well-being in 380 white males and females aged 50 to 75 years to determine if one may predict continuity across life stages. She found that, contrary to disengagement and activity theories, there was only a weak correlation between activity levels and psychological well-being; that is to say, different variables predict the two phenomena. Personality factors were better predictors of psychological well-being than were social status factors, and social status factors better predicted activity.

Thus, one may conclude that neither disengagement nor activity and psychological well-being are outgrowths of the aging process. Rather, they are the products of long-term personality or social processes that are effective on an individual basis. To put it more simply, some older people have high or low activity levels because they always have had high or low activity levels; the same may be said for psychological well-being.

After the Second World War, modernization theorists and age stratification theorists began to view societies developmentally with regard to urbanization and industrialization. People lived longer in more developed cultures, which resulted in more older people surviving. This resulted in competition for jobs, forced retirement, and/or disengagement, as technological advances caused the need for relocation and the loss of their status as older people became more common and were no longer something "special." One possible result of this is a collapse of traditional family structures, according to Donald Cowgill and Lowell Holmes.

Matilda White Riley's theory of age stratification from the 1970s looked at the relationship between social structure and age across the life course. Those individuals who are born in the same age cohort (roughly similar to age sets in many traditional societies) will have many experiences in common. These experiences will be different for each generation even when the experiences have been generated by the same events, for example when a population has experienced a war or natural disaster: Children are impacted differently than are adults; older adults are impacted differently than are younger adults. This theory allows us to view the different ways in which age cohorts may react to life events, and how such life events affect the structure of the society.

By the 1990s aging research had shifted to family gerontology, according to Katherine R. Allen, Rosemary Blieszner, and Karen A. Roberto. Allen and her colleagues examined 908 articles and 30 books on family gerontology published in the 1990s and discovered a shift in the field of aging individuals with regard to family social relations. By far the largest focus of the articles was on caregiving (32.6%); the next largest category was social support and social networks at only 13.7%, followed by parent–adult child relations at 10.1%, and marital status transitions at 9.5%. Further, they found that the students of later life are developing an appreciation for pluralism and resilience strengthened by the incorporation of feminist and life course approaches. Likewise, there has been greater sophistication in the use of longitudinal data, especially as the focus has shifted from exclusively studying the aging individual to the individual within the familial matrix. This, they say, forces a chronological variable into the research, especially as there is no agreed-upon chronological definition of middle age (e.g., becoming a parent or grandparent) and major life events no longer can be predicted even by gender). Indeed, the family within which one ages may be a chosen family rather than a biological one, through adoption or choosing a favorite niece or nephew to become analogous to a daughter or son. The feminist approach began to focus on female intergenerational dyads (mother–daughter ties); daughters are three times more likely to give care to aging parents than are sons, even if the sons live closer. Ironically, daughters-in-law are more likely to be the caregivers than are sons, as demonstrated by Kathleen Lynch's and Eithne McLaughlin's observations on caring labor and love labor in modern Ireland.

For Allen and colleagues, the life course perspective is the major theoretical advance in gerontology during the 1990s. Life course studies focusing on historical and social processes and their impacts upon individuals answer two important considerations: how individuals change over time and how their changes are linked to other members of their families. Longitudinal approaches increasingly are employing narrative methods to discover subjective meanings that individuals use to construct their lives. Through the narrative interplay of historical events and self-perception we can create our "selves" as we need them to be.

Gestation Period

The gestation period is the length of time, in viviparous (live-bearing) animals) needed for a fetus to develop inside the body of its mother. Gestation begins with conception (the implantation of the embryo in the uterus) and ends with labor and birth.

The length of the gestational period is species-specific, correlating somewhat with the body size for any given species, with larger species generally having a more prolonged gestational period. The gestational period is therefore quite short for very small mammals (21 days for mice), is longer for medium-sized animals (approximately 60 days for cats, dogs, and raccoons), and is quite lengthy for such large animals as rhinoceros (16 months) or whales (18 months). The shortest gestation period is that of the opossum (12 days), and the longest known gestation period for any animal is that of the elephant (18–22 months). For humans, the gestation period is normally 40 weeks (280 days), measured from the first day of the mother's last menstrual period.

Neonate Type

Although the length of the gestation period is generally correlated to an animal's body size, it is also determined by the state of development at birth for offspring of that species. Among mammals, there are three different groups that can be defined by the level of gestational development of their offspring at birth, and these groupings have proven (through fossil evidence) to be remarkably consistent throughout evolutionary history. Marsupials, which have the shortest gestation periods of all animals, are considered "superaltricial," with offspring that are very underdeveloped at birth and usually crawl into a pouch of some kind to continue their development before being able to survive detached from their mother's body. A second group of mammals includes insectivores, carnivores, and rodents. They have somewhat longer gestational periods and give birth to "altricial" offspring, which are generally poorly developed and typically must develop in a nest or burrow for some period after birth so that they can continue to grow and learn how to move around independently. Altricial offspring are still underdeveloped at birth, being usually hairless and with their eyes and ears sealed off by membranes. Altricial animals bear multiple offspring in litters and tend to have shorter gestation periods, reflecting the fact that the mother has limited space in her womb for completing development prior to birth. In contrast, a third group of mammals (primates, whales, dolphins, and hoofed mammals) has very long gestational periods and usually gives birth to only one or two well-developed "precocial" offspring that are relatively active soon after birth; they are born with fully developed vision and hearing, and are protected by fur and hair. This type of gestation is most common in animals that live out in the open, exposed to the elements, and are unable to conceal their young in burrows or caves.

Each main mammal group is therefore characterized by the type of neonate (altricial, superaltricial, or precocial) that its members produce, and by the length of gestational period typical of that group. Insectivores, tree shrews, carnivores, and many rodents have short gestational periods and bear altricial offspring; hoofed mammals, hyraxes, elephants, cetaceans (whales), pinnipeds (walruses, seals, and sea lions), primates, and hystricomorph rodents (Old World porcupines) bear precocial offspring after a fairly long gestational period. In fact, phylogenetic groupings have more impact on the length of the gestational period than animal body size does; the gestation period for an animal that bears precocial offspring will typically be three times longer than that for an animal of the same body size that bears altricial offspring.

Gestational Age

The gestational age of a fetus is a measure of how far along it is in the gestational period. Since the exact time of conception is not always known, the beginning of gestation is usually dated from a particular point in the reproductive cycle of any given species, or is estimated based on the size of the developing fetus. In humans, for example, gestational age is projected by a measure of time elapsed since the first day of the mother's last menstrual period, or is calculated with an ultrasound examination (usually administered between the 8th and 18th weeks of pregnancy), which uses the size of the developing fetus as the most accurate measure for dating conception and projecting when full development and birth will occur.

The gestational period is divided into three major phases: the preimplantation phase (from fertilization to implantation in the mother's womb), an embryonic phase (from implantation to the formation of recognizable organs), and a fetal phase (from organ formation to birth). These phases are called trimesters. In humans, each phase lasts about 3 months; the first trimester lasts from weeks 1 through 12, the second from weeks 13 through 27, and the third from weeks 28 to 40. In some mammals, the gestation period is extended to include an additional phase known as delayed implantation, or embryonic diapause, that precedes the embryonic phase. In these instances, the fertilized egg develops into a blastocyst (forming a hollow ball of cells), but then it stops developing and remains free in the womb rather than implanting in the wall of the womb (the usual next step in gestational development for most mammals). Delayed implantation is a strategy used by animals to delay the birth of a fetus until such external variables as food or weather are favorable for the survival of offspring, or in some cases as a way of holding potential offspring in reserve to immediately replace older offspring that do not survive long after birth. Other factors that influence the length of the gestational period in minor ways include gender (males take a few days longer than females), the number of young (single young take a few days longer than multiples), and heredity through the maternal line. In general, though, there is very little variation in the length of the gestational period within the same species, that is, 4% or less variability.

Gibran, Kahlil (1883–1931)

The writings of Kahlil Gibran, the popular 20th-century poet, philosopher, and artist, have been admired by millions and translated into over a dozen languages. By the time of his death, he had established a reputation in both the English and Arabic-speaking worlds. He never won critical or scholarly acclaim, but his style prompted the coining of a literary term, *Gibranism*, to describe the poised and poetic quality of his prose, which expressed an intense need for self-reflection and self-fulfillment. Throughout his life, he was primarily religiously nondenominational, seeking wisdom and truth from within instead. His writings reflect a preoccupation with mysteries and with deep spiritual meaning; he describes and reflects on his encounters with, and understandings of, godliness and addresses perennial themes such as Time.

Gibran was born in Bsherri (Bechari), Lebanon, in 1883. When he was 12, his family moved to the United States and settled in Boston, Massachusetts. After 2 years, Gibran went to Paris to study art under Auguste Rodin, at the famous Ecole des Beaux Arts. In Paris, Gibran also began to write plays and short stories in the Arabic language.

In 1904, he moved back to the United States and spent time living in both Boston and New York. While working in New York, he wrote his most popular literary works, *The Prophet* (1923), and *Jesus the Son of Man: His Words and His*

Deeds as Told and Recorded by Those Who Knew Him (1928). *The Prophet* included a series of poems on topics such as love, marriage, and children, and included a passage titled *On Time,* in which Gibran says time, like love, is undivided and spaceless.

Gibran's ability to paint and draw enabled him to illustrate many of his own books. Critics often cited the influences biblical literature had on Gibran's writings, and his lyrical passages are commonly read at baptisms, funerals, and weddings throughout the Western world.

Some of his other works include *Nymphs in the Valley* (1948), *Tears and Laughter* (1949), *The Madman: His Parables and Prose Poems* (1918), *Spirits Rebellious* (1946), *The Wanderer: His Parables and His Sayings* (1932), and *The Garden of the Prophet* (1933). His relationship with Mary Haskell, a teacher in Boston, is captured in *Beloved Prophet: The Love Letters of Kahlil Gibran and Mary Haskell, and her Private Journal* (1972).

In 1999, the Arab American Institute founded an annual *Kahlil Gibran Spirit of Humanity Award* that recognizes individuals, organizations, corporations, and communities whose actions demonstrate leadership in supporting and promoting coexistence, diversity, cultural interaction, inclusion, and democratic and humanitarian values across racial, ethnic, and religious groups.

Ginkgo Trees

Ginkgo biloba is the last surviving species of Ginkgophyta, a phylum of long-lived, vascular plants that evolved during the Permian period some 250 million years ago. Ginkgo trees, once thought extinct, are sometimes called living fossils due to the strong resemblance between the modern form and ancient remains preserved in the geologic record. The popularity of ornamental ginkgo trees in Asia has led to their widespread cultivation and dissemination.

The ginkgo tree is one of the best-known examples of a living fossil. This ancient tree represents a primitive family of trees common 160 million years ago in China. The ginkgo thrives in well-drained, loamy soil and is particularly resistant to modern pollutants, wind, pests, and disease.

Source: Michael Pettigrew/iStockphoto.

Ginkgos are medium-large trees that can live for hundreds of years, attaining a height of 30 meters and a trunk diameter of 2 meters. A few exceptional specimens may exceed 1,000 years in age and proportions far in excess of these. They comprise a unique division of the gymnosperms, an important seed-bearing plant group that includes cycads, conifers, and ferns. Ginkgos are easily recognized by their leaves, which look like a two-lobed fan (hence *biloba*).

Ginkgos are dioecious plants, meaning that male and female reproductive organs are borne on separate trees. Male trees form a small cone that produces motile sperm. On the female tree, fertilized seeds mature into a tan, fleshy fruit 25–40 millimeters long. These fruits are rich in butyric acid, which when crushed can release an odor likened to rancid butter. These sorts of naturally occurring chemicals in the tree are thought to have evolved for better resistance to insects and bacteria, or even to help ward off herbivores.

Ginkgophyta trees arose during the Permian, approximately 250 million years ago, and to the present day have left numerous fossils of their distinctive leaves, stems, seeds, and wood. After their emergence the group continued to spread and diversify, surviving the relatively arid Triassic to form part of the great forests of the Jurassic when the genus *Ginkgo* itself first evolved—approximately 170 million years ago. Since the end of the Cretaceous, the ginkgo has suffered from a steady constriction of its range, abundance, and diversity. The precise reasons are unknown, but today the ginkgo is all but extinct in the wild; a few small native populations remain in the Zhejiang province of China, scattered in elevated broadleaved forests.

In some ways, the ginkgo has been reclaiming its former territory. In China the trees have long been cultivated in the gardens of Buddhist temples (and occasionally as a food source). From there they spread to Japan, and in the 17th century to Europe and other Western countries. In modern cities all over the world, they have become a shade tree of choice. The ginkgo is well suited to the urban landscape, as it requires minimal maintenance. It also has a high tolerance for pollution and resistance against disease.

Ginkgo seeds are used in traditional Asian medicine, and the cooked seeds can even be eaten. More recently, ginkgo leaf extract has been packaged to treat a variety of ailments. This utilizes the plant's naturally occurring concentration of flavonoids, a group of antioxidants found in certain fruits and vegetables. Although scientific research has not yet supported the health benefits attributed to ginkgo, some promising lines of pharmaceutical research are investigating its effects on dementia and Alzheimer's disease.

Ginkgos are true icons of long-term survival; their modern form is quite similar to that of fossils 250 million years old. The tree has survived trampling hordes of herbivorous dinosaurs and major environmental catastrophes. Its extremely limited native populations, however, testify to enormous ecological pressure—the ginkgo has been struggling to survive in the present era. In the wild their relatively inefficient reproductive system, slow regeneration, and lack of diversity have exacerbated the damage from habitat loss. *Ginkgo biloba* faces a very high risk of extinction in the wild; it is currently classified as an endangered species. After successfully adapting to nature's challenges over hundreds of millions of years, let us hope that ginkgo remains a *living* fossil rather than a literal one.

Glaciers

Glaciers have been an important feature of the earth's landscape during the present Cenozoic era, which spans about 65 to 70 million years. Cooling near the end of the era began in the Pliocene epoch, and mountain glaciation in the western United States occurred somewhere between 1 and 2 million years ago. The Cenozoic era is divided into the Tertiary and Quaternary periods, with the most recent glaciation occurring during the Quaternary period, which covers approximately one million years before the present (BP). This period is divided into the Pleistocene and Holocene or Recent epochs. During the Pleistocene, four major glacial advances and three interglacial stages occurred. The Holocene or Recent epoch spans a period of approximately 11,000 years BP. During this time, the fourth interglacial stage or a temperature increase has been occurring, including melting ice and a rise in sea level. This may last for tens of thousands of years, and may be followed by another future period of cooling and the growth of glaciers.

Prior to this present age of Pleistocene glaciers, there were at least five other known glacier periods, dating back to two occurrences of glaciation in Precambrian times. Toward the end of the Permian period glaciers appeared again, and they were rather widespread. During the early and late portions of the Cretaceous period glaciers appeared once more. The occurrence of glaciers is evidently a cyclical phenomenon, but the precise cause of their appearance is not known.

During the Pleistocene glaciers were widespread, covering both polar regions and extending outward a considerable distance, covering approximately 30% of the earth's total land area. In the present Holocene epoch, the earth is witnessing a global warming as well as a global dimming: Both of these appear to be antagonized by increased human interference. All glaciers are receding, and have been for thousands of years, but at seemingly a much faster rate now than when they were flowing forth. Consequently, the sea level rose at an average rate of about 6 inches per 100 years during the Holocene. A noticeable increase has been noted during the last several hundred years, however, and this is expected to continue.

In the 19th century, Louis Agassiz, like James Hutton and other scientists in the century before, asserted that the large boulders in the valleys were not placed there by Noah's flood, but were once plucked by erosion out of the advancing ice, sometimes a mile or more deep, and then deposited by a receding ice flow. Agassiz's views were initially met with skepticism and hostility by most of the audience at a meeting of the Swiss Society of Natural Sciences; widespread acceptance came only gradually, later on.

Glaciers are commonly defined as either continental or mountain types. Continental glaciers begin in an area with polar temperatures and extremely large accumulations of snow. There were three areas in the northern hemisphere where this most strikingly occurred during the Pleistocene; in Europe over the northern Baltic Sea and much of Norway, in North America over Hudson Bay and north central Canada, and over northern Siberia. Not to be overlooked are the general expanse of the Arctic icecap including Greenland and other parts of the northern hemisphere, as well as the massive Antarctic continent in the southern hemisphere. These continental glaciers appear to be located on or very near shields consisting of Precambrian igneous and metamorphic rock. With regard to mountain glaciers, the Alps, Andes, Rockies, and the vast Himalayan chain are all fine examples of mountainous glaciated terrains. Also, snow and ice occur on isolated mountain peaks in Hawaii, Japan, and Kenya, to mention a few.

Continental Glaciers

Continental glaciers begin with a decrease in temperature and an accumulation of snow, over a long period, tens of thousands of years. The snow is compacted by its own weight. Eventually, the snow at the deepest level begins to form ice. Glacial or moving ice is subjected to immense pressure and is transformed molecularly into an extremely hard metamorphic rock. Subsequent snows provide added weight and pressure, and the deepest ice begins to move outward by the force of gravity into lobes that move more rapidly along lines of least resistance. The lobes are guided by original terrain features such as mountains, hills, and plains, and the relative resistance of the various types of earth materials and rock structures. The magnitude of accumulation at the glacier's source is believed to be more than 10,000 feet in some cases, and the outward movement is estimated at more than a thousand miles, perhaps at speeds of 30 miles per year or even more.

Continental glaciers sculpt the land by erosion, carving out a variety of landforms. The moving ice deposits the carried sedimentary materials as depositional features upon melting. Some of the eroded features that can be seen today are due to abrasion by rocks carried along by the ice, leaving behind striations, grooves, and polished surfaces. Also left behind are gouged-out valleys that were deeper and wider areas of softer rock, forming depressions such as the Great Lakes, *cuestas* or edges of land surfaces formed by resistant rock strata such as that of the Niagara Cuesta including Niagara Falls, and smaller hills known as *roche moutonée* formed by resistant rock. The materials are deposited in recessional and terminal moraines, or in ridge-like terrains that are accumulated during stand-still periods. As the ice recedes in a sometimes erratic manner, it leaves behind landforms such as ground moraines consisting of glacial till, also known as tillite, along with such features as kames and kettles, drumlins and eskers, resulting in a hummocky topography. Braided streams also result from retreating glaciers, as well as "misfit" valleys where the valley width is much narrower or wider than it should be for the width of the stream currently flowing through it. For example, the upper Mississippi, the Des Moines, and some of the other streams in the midwestern United States are considered misfit streams. In general, the landscape where continental glaciation has taken place is quite depressed compared to unglaciated areas, and exceedingly complex as compared to stream, eolian, or coastal landscapes. This is, in part, due to a yet-to-be-integrated drainage pattern and the periglacial landscape of outwash materials.

Mountain Glaciers

Mountain glaciers begin with a cold temperature and an accumulation of precipitation at the highest elevations. Over a long period of time, as with continental glaciers, snow is compacted, eventually forming ice. The glacial ice begins to move downward by gravity along lines of least resistance, forming tongues, usually in former stream valleys. In many cases these tongues of ice find their way to sea level, and when the ice recedes the fjords remain behind as remnants.

Mountain glaciers sculpt valleys by eroding various types and hardnesses of rock. Then the melting ice leaves the sculpted materials in depositional features. Eroded features include *cirques* or bowl-shaped indentations near the peaks, or matterhorns where the glaciers begin, the knife-like ridges between the valleys called *arêtes*, and low places in the ridges called *col*s. Valleys that were originally V-shaped due to stream action become U-shaped due to ice action, and some have depressions called *tarns*. Retreating glaciers deposit terminal and recessional moraines during stillstands, as well as lateral moraines along their edges as they retreat and medial moraines where two lateral moraines have merged. Glacial till carried from the eroded areas is dropped by the melting ice to form braided streams and outwash plains. In general, mountainous terrain that has been glaciated appears much more concise, complex, and abrupt when compared to unglaciated mountains. For example, the Matterhorn and its descending glaciers in the Swiss Alps are much more sharply unique in appearance as compared to Mount LeConte and other unglaciated peaks and their descending streams in the Great Smoky Mountains of the United States.

Time, distance, and speed play their part in sculpting the earth. Glaciers, like wind, streams, waves, and currents, flow. How fast does the ice flow? How far does the ice flow? How long does the ice take to flow? Winds move much faster than ice and travel the farthest, across land and sea, while streams are restricted to the land, and waves and currents are restricted to the sea. Glaciers move slowly across the land and out into the sea. If they didn't, there would be no icebergs today!

Glacial Movement and Climate Change

Glaciers, at their maximum extent during the Pleistocene, were widespread, covering more than an estimated 45 million square kilometers. Glacial ice moves much like a stream, in that the fastest motion is found in the center of the lobe or tongue. That is, the slippage and flowage is considerably slower closer to the rock formations where plucking and erosion by the ice adds friction. This is tempered by variations in rock hardness and degree of slope. Consequently, there is a huge variation in the mean rate of ice advance. Some of the intermittent advances of mountain glaciers with short duration vary between 2.4 and 32.3 meters per day, with advances between 606 and 4,850 meters per year. For long-term advances of mountain glaciers, the mean rate varies between 80 and 128 meters per year over a period of 100 years.

Continental glacier movement is much more difficult if not impossible to measure, as continental glaciers either no longer exist or are in a recessional mode. It is known that four major ice advances and accompanying recessions occurred during the Pleistocene, with their nomenclature varying depending on location and language. But these major advances included minor advances and recessions. For example, seven substages of the Wisconsin glacial stage in the midwestern United States have been observed. In the western hemisphere, numerous lobes descended from the Laurentide of Canada across the plains of the midwestern United States, forming a complex landscape. From radiocarbon dating it is known that ice receded from north-central Iowa less than 3,000 years before the present, and that near the bottom of the Des Moines lobe the oldest drift is older than 40,000 years before present. This is presumed to be during the Wisconsin, which began about 70,000 years before present. The maximum glacial extent during the Wisconsin occurred about 14,000 years before present, and a considerable amount of glacial activity occurring before and after, including loess deposition and the development of the present day paleosols, all occurred during the interglacial stages. It can be assumed that similar circumstances occurred in Europe and Siberia.

Climate fluctuations during the Pleistocene and Holocene, coupled with periglacial effects, are felt around the world, especially eustasy—worldwide change in sea level. The outwash from glaciers is the most obvious periglacial activity, along with the less obvious permafrost. Also, glacial rebound is evident where the deepest ice has melted away, such as Hudson Bay. Then too, there is the migration of vegetation poleward as temperature and moisture changed. Humankind soon followed the retreating glaciers.

Today, scientists worldwide are monitoring climate change, including rising sea levels, something that has been happening since the late 17th century. Ancient shorelines around the world show that when glaciers were near or at their minimum extent, sea level was about 400 feet higher than it is today. If the sea level continues to rise, then it may reach that stage again; how soon no one knows for sure, but it will continue to rise if global warming and global dimming continue. On the other hand, when and if the present interglacial stage ends, the sea level may fall. During the Illinoisan glacial stage when ice was at its maximum, the sea level is estimated to have been 600 feet below the present level, a condition that is difficult for many people even to imagine.

Although glaciers worldwide are receding at the present time, within the next 90,000 years or so they will again expand across large portions of the earth's landmasses, especially those located in the higher latitudes and altitudes.

Globalization

Globalization refers to the close relationship and interdependence of economic, social, political, cultural, and ecological connections of places in our world. It refers to the intensification of interconnectedness on a global scale. With increased means of communication and travel from 20th-century innovations in technology there is no doubt that our world is shrinking. Never before has it been so easy for people, things, capital, and ideas to move around. Further, globalization has reordered the experience of time and space. Because economic and social processes have shrunk, distance and time are less of a constraint on the organization of human activity. Technological and economic advances have eliminated barriers of space by time and have reorganized time to overcome barriers of space. For example, the same media events are covered all over the world, making it possible for people in, say, the United States and Japan to have access to the same information. Also, this has allowed extremely remote areas of the world to interact with cosmopolitan cities and perhaps with places on the other side of the globe. In other words, time is shortening and space is shrinking. The pace of life is increasing, and the amount of time needed to do things is becoming much shorter. Something that is happening on the other side of the globe can deeply impact people and places vast distances away. Increasingly, economic and social life is becoming standardized around the world.

Globalization in a Historical Context

Forms of globalization were present as early as the 17th century with the rise of the Dutch East India Company, which is said to be the first multinational corporation because it was the first company to share the risk and create joint ownership by offering shares. During the 19th century, liberalization resulted in a rapid growth of international trade and investment between Europe, its colonies, and the United States. This "First Era of Globalization" began to crumble at the onset of World War I and collapsed entirely during the 1920s and 1930s. Arguments and critiques arose against imperialism and the exploitation of developing nations by developed nations.

International trade has grown tremendously since the 1950s; according to estimates, trade has increased from $320 billion to $6.8 trillion. As a result, people from around the world have access to a greater selection of products.

Much of what we are witnessing in the world today concerning globalization started in the 1970s with what is termed a "crisis of overaccumulation" based on the Henry Ford system of mass production. The Ford model, which is based on the mass production of standardized parts, became so successful that Western nations began to overproduce. This resulted in mass layoffs of employees in addition to reducing the demand for products as markets became saturated. There were not enough consumers for all of the goods produced, making corporate profits and government revenues dwindle. Attempts to solve the problem by printing extra money only created inflation. In the midst of this crisis, a new system emerged that depended upon flexibility in labor markets, products, and consumption. During this time new sectors of production emerged and niche markets as well as a greater increase of commercial, technological, and organizational improvements. Labor markets were widened with outsourcing and subcontracting strategies along with the hiring of large numbers of part-time, temporary, and seasonal workers. Markets began to cater to fashion niche markets, recreational activities, and lifestyles, making the pace of economic and social life speed up (popular culture, fashion, sports and leisure, video and children's games). Also, in an attempt to increase profits, many multinational corporations are outsourcing their work. Outsourcing is defined as the delegation of non core activities that the organization was once responsible for but has now hired an outside entity to do. The most common outsourcing jobs include call centers, e-mail services, and payroll. The trend grew during the 1980s as a major way for corporations to save money. Much of the outsourced jobs have gone to China, India, Pakistan, and Vietnam. Advances in technology have reduced the cost of trade tremendously. Satellite communications deployed since the 1970s have increased communications and at a lower cost. Air freight rates have been reduced drastically along with the cost of sea and rail transport. The resulting economic growth also has brought about economic, political, and social disruption. Consequently, the World Trade Organization (WTO) was created to mediate disputes with regard to trading and to create a platform of trading along with GATT (General Agreement on Tariffs and Trade), which was formed to reduce barriers to trade after World War II. In recent times, globalization can be seen in the agreements on trade among countries, such as the one created by NAFTA.

North American Free Trade Agreement

The North American Free Trade Agreement (NAFTA) was created on January 1, 1994, as a free trade agreement between Canada, the United States, and Mexico. The plan was to phase out the majority of tariffs between the countries to encourage trade. Several economists have analyzed the effects of NAFTA and have reported that it has been beneficial because poverty rates have lowered and real income has increased. Over the years trade has increased dramatically between the three countries. Between 1993 and 2004, total trade with U.S. partners increased by 129.3% (Canada 110.1% and Mexico 100.9%).

Social Aspects of Globalization

Interestingly, social life is equally and utterly impacted by these alterations of time and space. Throughout the course of human history, people have interacted with one another mostly face to face. Daily human life is filled with interactions during localized activities. Today, however, more often than not, a person's physical presence is not required. Many tasks can be handled remotely, something made possible by transportation and communication systems. In that sense, social life is altered by the absence of locality, and it fosters relations between people who are too far apart for face-to-face contact. Place becomes less important as the physical setting for social activity, and modern localities are created over long distances. Although place and locale are still significant in daily life, social connections become less dependent on face-to-face interactions, making the local and global intertwined as never before. And, as people continue to live their "local" lives they inevitably are connected globally. Distant events impact local happenings and local developments can have global repercussions that stretch beyond national boundaries.

Culture and Globalization

In the anthropological sense, *culture* refers to a group of individuals—a nation, an ethnicity, a tribe—who share a system of beliefs that define their world and who interpret meaning based on their shared set of beliefs. Traditionally, this definition has been tied to a specific territory. We used terms like "American culture" or "Latin culture" loosely; they brought up images of a specific geographic region or particular country. These images often have certain attributes associated with that particular region. Conversely, in the present context of globalization it is unreasonable to equate a specific culture with a particular geographic area because locales are woven intricately into one another. In other words, the boundaries are blurred. For example, Western cultural objects like clothing, food, and music are now present in nearly all parts of the world. Anthropologists have defined the weakening of the ties between culture and place as "deterritorialization," meaning cultural processes that we once thought of as taking place in a specific region have transcended these specific territorial bounds. This is not to say that cultures are free floating, but there is an uprooting and a reinserting of culture going on due to the flexibility and movement in our current world. Anthropologists have defined cultures as sharing a certain space or "community." A community setting can signify anything from a village to a nation-state. Creating a group of people within a bounded area assumes that this community shares a strong bond within this space. In addition, this space is used to reinforce a worldview and a set of rules to live by, thus creating a certain cultural coherence. In the past, we have understood the "anthropological other" by comparing community with community. Migration is one event that has historically challenged social spaces, such as along the U.S.–Mexico border. Since the 1960s, however, transnational capitalism and migration have strongly influenced remote societies and have changed ideas of culture. For example, in remote villages like Aguililla, Mexico, almost all families had a family member abroad; the local economy depended heavily on the influx of dollars, and many farms were being sustained by family remittances. As large-scale industrial agriculture takes over the Mexican landscape, small-scale subsistence farmers are no longer able to sustain themselves using their traditional practices. The cultivation of maize has been present in Mexico as a primary means of subsistence for 6,000 years. The fact is that people in rural villages can no longer rely solely on local resources to meet their needs. In a globalized world where the local intersects with the global, markets have forced small communities to change and people to migrate. Patterns of transnational migration are prevalent between Mexico and the United States. Most Mexican migrant workers come to work menial jobs in the service sector as dishwashers, janitors, hotel workers, and gardeners. The majority stay in the United States briefly, and those who stay longer remain deeply connected to their families. Their main goal is to finance local dreams by having access to outside funds. Further, the

U.S. economy has become dependent on these workers who occupy society's economic "bottom rung," creating social spaces and communities that transcend geopolitical borders, and finding that their most important kin and friends live hundreds of miles away from them.

Adverse Effects of Globalization

Although trade has increased and indexes for poverty seem to have been lowered according to economists' standards, there are dilemmas with this particular style of free trade. Some would argue that free trade agreements such as NAFTA have damaged and further marginalized large segments of the world's population. It has been demonstrated that although globalization does help to grow economies, it does not do so evenly. The meager share of global income gained by the poorest people in the world has dropped from 2.3% to 1.4% over the past 10 years. While it is true that transportation and communication have made it easier and quicker for people to get around, it is not true for all people in all places. Some people have the social and economic resources to take advantage of these advancements; others do not. Some people have little or no access to electricity, telephone, and Internet service or the opportunity to buy an airplane ticket. Chances are these people will never have this opportunity in their lifetime. Not everybody on the planet is feeling the benefits. There are several places in Latin America and Africa that are literally not even on the map of telecommunications, world trade, and finance. Even so, they can feel the pressure of the market. Such places have few or no circuits connecting them to the outside world other than the communication and transportation that passes over or through them. In this rapid-paced and changing world they are the ones who are forgotten.

Maquiladoras

Maquiladoras are foreign-owned assembly plants in Mexico, primarily located along the border between the United States and Mexico. Maquiladoras first appeared in Mexico in the 1960s; by 1990 there were 2,000 operating with 500,000 workers. These factories produce mainly electronics, clothing, plastics, furniture, appliances, and auto parts. Between 80% and 90% of the goods produced in Mexico are shipped to consumers in the United States. Most people who move from rural settings in search of better opportunities and work in maquiladoras find deplorable living conditions. And, while some company owners have worked to improve the working conditions of their employees, numerous factories misuse their workers. In some instances, reports tell of maquiladora owners subjecting employees to more than 75-hour workweeks without proper breaks. Some 80% of the employees are women because they are fast at repetitive tasks and they get paid a lower wage than men. Minimum wage is $3.40 per day (vs. $6.55 per hour in the U.S.). There have been numerous sexual harassment incidents or the firing of women if they become pregnant. Also, Mexican men resent that women are being hired over men for jobs, leaving women subject to retaliation and violence. In the city of Juarez, alone, more than 200 women who worked for the factories have been murdered. Further, Juarez and other cities lack infrastructure like electricity, sewage, and safe drinking water to sustain the influx of migrants to the cities with factories. For example, since NAFTA the employment rate in Juarez has risen 54%, yet Juarez has no waste treatment facility to treat sewage from the 1.3 million people who live there. Other related problems are that factories set up in these border towns are not held to strict guidelines for environmental protection, which leads to contamination of the air and water supplies. And workers are exposed to dangerous chemicals without any protective wear.

Anti-Globalization or Global Justice Movements

There are many worldwide who do not support the current political and economic system of neoliberal globalization. People involved in global justice movements advocate anarchism, socialism, or social democracy and are against the ruling elites who wish to expand and control world markets for their own gain. These movements call for reforms in the current capitalist model where multinational corporations control 70% of trade in the world market, and for moving toward greater social welfare reforms. Global justice seekers place greater emphasis on equal rights, environmental awareness, and cultural diversity. Alternative ways of growing economies are also present in the movement, where small-scale producers band together to create alternative economies for the goods and services produced. One example is Kallari, an organization of Indigenous Kichwa artisans and farmers in Ecuador who produce coffee, chocolate, handcrafts, and jewelry and sell locally and globally. The Kichwa face strong pressure from the world market through encroachments and a shrinking land base due to outside multinational corporations that drill for oil and mine for gold. Since the Kichwa lacked infrastructure and the support of local and national governments, they needed to organize their own economy. With the assistance of the Jatun Sacha Foundation and its director, Judy Logback, they have been able to enter the world market and to be paid a fair and living wage. In addition, the have opened their own café where they sell their products in Ecuador. Further, they ship goods internationally to niche markets that support environmentally conscious and fairly traded goods. The project has been active for nearly 10 years and has met with great success, with nearly 25 Kichwa communities participating.

Conclusion

For some, globalization is about free trade between countries and the growing of economies that include new job opportunities, while for others it is another way for the rich to prosper at the expense of the poor with little regard for social welfare, human rights, or the environment. Further, globalization has altered space and time for social intercourse and the meaning of community. It remains to be seen how we will redefine our world and our social relationships along with our political economy based upon our values and where we are "located" on the globe.

Global Warming

Even though the global temperature has been changing for millions of years, this is the first century in which we are seeing global changes occur quickly relative to the time that human and animal life activity has been documented. Human-induced changes to global temperature are now evident, whereas the changes in the past were seen as natural phenomena. For example, in the preindustrial era the concentration of CO_2 measured 280 parts per million; by 2005, that had increased to 382 parts per million.

Despite mounting empirical evidence of global temperature change over the past few centuries, it is only relatively recently that scientists have taken note of global temperature changes and publicized them. The 1970s was the first decade in which the general public began to take note of environmental issues. In the United States this occurred through the efforts of environmentalists and scientists who pressured government to institute sweeping changes to U.S. environmental policy. Subsequently, more than 15 national acts of environmental legislation have focused on a range of issues from clean water to endangered species. These new forms of environmental legislation did not, however, take into account increases in fossil fuel emissions that occur with increased global dependence on manufacturing, energy generation, and automobile use. The U.S.

Environmental Protection Agency, created in 1970, did not provide the U.S. auto industry with fuel emission or miles-per-gallon standards, which eventually resulted in millions of tons of carbon entering the atmosphere every year. By not recognizing this serious emission problem, policymakers did not acknowledge changes in potential carbon loads to the atmosphere. Scientists now estimate that global warming will continue, despite our actions to slow the changes. There is concern that we will quickly near what is said to be the ultimate carbon threshold of 480 parts per million in our planet's atmosphere.

The science behind global climate change is complicated. It takes time to establish patterns and understanding of the problem. The U.S. Congress heard first testimony on global warming in 1973; following that, an international campaign was launched to explain the future dangers if such a problem were to be ignored. Scientists predicted global catastrophes such as the melting of the polar ice caps, coastal flooding, and widespread migration of affected populations. We have finally begun to acknowledge the connection between fossil fuel emissions and increased global temperature. However, there remains ongoing debate over whether the problem exists as fact or is a theory.

Increased media coverage of global warming has been due in part to former Vice President Al Gore's 3-decade-long research and investigation into climate change, which culminated in the Academy Award-winning documentary, *An Inconvenient Truth,* a national theatrical film release; a book of the same title; and an international lecture series. Public awareness of this issue has increased, and individual and community efforts to help reduce the impact of global climate change are more widespread. It is not yet clear to what extent social behavior is following public sentiment that now supports societal action to curb the impacts of global climate change. Longitudinal, empirical research will be needed to determine these outcomes.

It has been projected that even if we decrease our carbon output now, it would have very little impact on current and future climate change trends. Notwithstanding, action is still encouraged in order not to escalate the problem. It has taken decades of data collection to determine if a global climate change pattern even exists. Even given this evidence, some still question the validity of the global climate change claims and data. Those who doubt the conclusions argue that longitudinal evidence has not shown that global warming is occurring, let alone creating serious environmental harm. This position, opponents claim, is being fueled by those who are closely allied with the fossil fuel industry and other manufacturers who stand to lose money if their primary source of business is replaced with less environmentally damaging alternatives. Proponents of alternative fuels have been encouraging these companies to invest in alternative, environmentally friendly technology, but with limited success to date.

Much of this debate is centered on time. On the one hand, advocates who support the need to recognize global warming argue that time is of the essence. They advocate for change now, given the likelihood that a planetary overload of carbon will reach dangerous levels in the next 20 years. In 2007, U.S. automobile fuel efficiency standards were 22 miles per gallon (mpg), and the U.S. government requires only a slight increase to 23.5 mpg by 2010. In November 2007, the U.S. Court of Appeals demanded that the Bush administration change the standards and answer some basic questions about why not all vehicles have to meet the current standard; for example, minivans and sport utility vehicles are allowed to be less fuel efficient than cars. The gathering of world leaders for the Kyoto Protocol of 1997 and in Bali, Indonesia, in 2007 indicated an urgent need to establish limits on carbon output to at least slow the effects of global climate change.

On the other hand, opponents argue that more time is needed to establish data trends that support the reality and consequences of global warming. U.S. energy policy does not support the global guidelines set forth in Kyoto, nor are current U.S. policymakers, along with China, willing to support any kind of mandatory carbon and fossil fuel emission reductions. However, there are movements toward tax incentives for voluntary reduction actions.

The full consequences of global warming will emerge only with time. Recognition of the importance of research in this area is reflected in the awarding of the 2007 Nobel Peace Prize to Al Gore and the scientists working with the United Nations International Panel on Climate Change. If momentum toward curbing global warming continues, perhaps the potential disastrous effects on human populations and the environment will be avoided. Yet, even with acknowledgment of the problem, significant changes to the national energy infrastructure have been slow in coming.

Scientists often rely on time through longitudinal studies to develop data trends over which people come to conclusions and take action. In response to the question of how quickly we need to begin to change our lifestyles and behaviors to make a difference in carbon output, some leading scientists claim that we have only 10 remaining years to reverse the effects of global climate change. Many others are calling for an 80% reduction in carbon emissions by 2050. The success of such reforms requires not only the time but also the will to implement far-reaching policy changes such as fuel economy standards, manufacturing caps on carbon, and clean energy options.

God, Sensorium of

Sensorium of God is a phrase Isaac Newton (1643–1727) used in his discussion to describe his notion of space and time. Newton saw space and time intricately associated with God, thus he used science and religion to explain how the universe functioned.

Newton saw space and time as being absolute and independent of any physical object. He believed space extended without limit in any direction and was immovable. He saw time as infinite both in the past and the future. He also noted that making measurements in absolute space would require using an object within absolute space, thus an absolutely stationary object. This is not possible given the law of gravity, according to which every object, including stellar objects, is influenced by universal gravitational forces. Therefore, no stationary object exists so no such measurement can be made. Instead, objects must be measured relative to another object, both of which are moving.

The sensorium of God was Newton's way of answering an old question in stellar physics: How do particles move? The assumptions of this theory are (1) all objects have substance and therefore have a place in space and (2) these objects are subject to time. Physicists of Newton's time could not imagine another possibility. Newton believed stellar and planetary movement could be determined and predicted using mathematics and mechanics based on Euclidean geometry and his theory of gravity. Building on the work of Galileo, Copernicus, and others, he developed a method of plotting an object in motion. His method uses a coordinate system to plot an object on the three spatial axes and one temporal axis. Thus, one can know the exact location of an object at a particular instant in time. He believed space was geometrically ordered and that objects moved in a straight line unless otherwise influenced by gravity or centripetal force. Thus, Newton's sensorium of God is connected to his famous three laws of motion and his law of universal gravity.

Newton was raised in the Protestant tradition, died a Roman Catholic, but held to a Unitarian belief system that was neither traditional nor orthodox. In his quest to unite knowledge and religious belief, Newton, being somewhat of a theologian as well as a scientist, connected this concept of absolute space with God. He saw God as not restricted to the physical universe; that is, God is both omnipresent (not limited to space) and eternal (beyond the bounds of time). Space and time serve as his sensorium, where God intimately and thoroughly perceives and understands objects and events. God is always present everywhere and is a part of every event. For Newton, God constitutes time and space, being equally present in all space and time.

Newton's work on space and time was revolutionary, with his book *Philosophiae Naturalis Principia Mathematica* considered the most important work ever written in the field of science. Although his attempt to unite belief and science has been largely downplayed, his theories continue to be foundational to the physical sciences.

God and Time

At the core of most religions is the concept that God, or the Transcendent, may be personal or impersonal. God is the creating power without being created. God is timeless and eternal. With the act of Creation, time came to exist. God is not only the first cause outside of time, but also the basis of time. Especially in Christianity, God is regarded as the starting point of being and time, as well as the end of both. Statements from the ancient world on these ideas can be found in Plato's dialogues (e.g., *The State* or *Timaeus*) and in Aristotle's *Physics* and *Metaphysics.* Classical positions are given in the teaching of Saint Augustine, chiefly based on the Platonic and Neoplatonic traditions, and of Saint Thomas Aquinas, based on Aristotelian philosophy. Rationalistic perspectives are represented by such thinkers as Giordano Bruno, Baruch de Spinoza, and Gottfried Wilhelm von Leibniz. They considered monistic thoughts, as well as pantheistic views, or the question of evil in the world. More recently, Pierre Teilhard de Chardin and Alfred North Whitehead present again considerations on God and time.

Plato and Aristotle

With his idea (form) of the Good, Plato (428–348 BCE) did not directly mention God. But the universal good, as characterized in *The State,* has qualities similar to those of God in the Christian tradition: eternal, indivisible, beyond space and time. In the Platonic dialogue *Timaeus,* God is spoken of as the *dêmiourgós* (demiurge), who built the world out of basic material. But this God is neither the Christian God, nor a creator out of nothing. He has only the function of giving order and reason to the qualities of the cosmos.

Aristotle (384–322 BCE), student-scholar of Plato, speaks in the *Physics* and in the *Metaphysics* of the (first) Unmoved Mover. This first principle, which gives motion to everything in the cosmos, does not itself move. The first principle is loved by everything, so all things in the cosmos move toward it as an aim (*télos*) in circles. By this nonmoving quality, the Unmoved Mover is beyond time, because moving can be measured only within time. The first principle is always the same; it is the "thinking of thinking" (*nóêsis noêseôs*), unchangeable like God. Though it is not the Christian God, the first principle is called "God" (*theós*) by Aristotle.

Augustine and Aquinas

Saint Augustine's (354–430) thoughts on time are embedded in his interpretation of Genesis as he presented them in book X, and especially in book XI, of his *Confessions.* According to Augustine, time (*tempus*) is linked with the Divine Creation (*creatio*). "Time" has no meaning before the Creation. Time did not exist before God created the universe. However, one could say that time was within God before the Creation. So it makes sense to speak of "time" only when there are processes of becoming and vanishing. Time gives natural processes both a basis and a framework in which they can progress.

Augustine is very honest when he says that he knows quite well what time is, as long as he is not asked to describe it. But when he is asked what time is, he does not know how to answer this question: "What is 'time' then? If nobody asks me, I know it; but if I were desirous to explain it to one that should ask me, plainly I know not" (*Quid est ergo tempus? Si nemo ex me quaerat, scio; si quaerenti explicare velim, nescio*). Therefore, one can say that time is very difficult to explain, but at first easy to understand. This sounds a bit paradoxical, but Augustine wants to reach a deeper philosophical understanding of time. So, he goes on with his own investigation.

Time is located in the mind (*animus*): past, present, and future (the three kinds of time) are all represented in mind as dimensions of mind. This also sounds a bit paradoxical, because past, present, and future are basically at the same time in the mind. Though a human only lives in the present, both the past and the future can be represented within the human mind. The past is represented in memory. In a further step, Augustine says that time is measured by the soul: "'Tis in thee, O my mind, that I measure my times" (*In te, anime meus, tempora mea metior*). Therefore, time is an extension of the human mind. Time is a representation in the mind and not an objective physical motion. We can see that Augustine's concept of time is very subjective, because time can be represented and measured only in the subject's mind. In this case, his position is different from the more objective point of view of the Platonic and Neoplatonic traditions.

Augustine points out that Christian eschatology, the doctrine of last things, teaches us that a human cannot fulfill time on his or her own. God will fulfill time when God returns in Christ at the end of our time. So, the perfection of everything can be done only by God, and it is nothing that happens in time; it is, in fact, the perfection of time out of time. Therefore, Augustine wrote that, in time and in the world, we can only use things, and God is the only one who can be enjoyed. In the last books of *The City of God,* especially in book XXII, Augustine shows us that Christian eschatology differs from political eschatology; the latter tries to create an earthly paradise with only political considerations, often linked with political ideologies and violence.

The love of God for a human and the love of a human for God keeps a human, during time, in relationship with God. If one is within the love of God, one can do whatever one wants to do, as it cannot be against the Almighty: "Love, and do what thou wilt."

God, the Sacred Trinity, is independent of time. God is over, behind, or next to time, because God is the eternal, pure being (*esse*) and has never been created. God is and always was, is and always will be; God is timeless without any changes. The universe, created by God, is within time. But the created universe is contingent, it is not a necessary being like God. God, existing out of time, is the only necessary being as a basic ground of contingent being in the universe and in our world.

With his early considerations on time in the 4th and 5th centuries, Augustine is the starting point of Christian theories of time. He influenced later thinkers deeply, especially thinkers during the scholastic period, such as Saint Thomas Aquinas (1224/1225–1274). But Augustine also influenced thoughts about "time" beyond Christianity: modern thinkers like Edmund Husserl (1859–1938), with his phenomenology of time; Henri Bergson (1859–1941), in whose thinking the durative aspect of time (*durée,* duration) is central; and Martin Heidegger (1889–1976), with his main work *Being and Time* (1927), refer directly or indirectly to Augustine's thoughts about time.

Time (*tempus*) for Saint Thomas Aquinas, as for Saint Augustine, is a phenomenon that has to do with the Divine Creation (*creatio*). God creates, as he is the first cause (*prima causa*). All the beings in the created world are creatures in time. Outside the world and the cosmos, time has no meaning and no use. Time appears together with Creation. All natural developments happen in time. Without time, humans could not recognize developments. Also, human processes, even social and moral processes, need time as a framework. As Saint Thomas pointed out in his early commentary to the sentences of Saint Peter Lombardus, time is also necessary for those processes in the mind, because it serves as a measurement for what we have in the mind.

In his main work, *Summa Theologiae,* Saint Thomas investigated time as an important phenomenon. Here, Aquinas differentiates time (*tempus*), which was for him well known as one of the 10 Aristotelian categories, from real eternity (*aeternitas*) and from eternal time (*aevum*). Aevum, "eternal time," is a kind of "infinite time" for Saint Thomas, as an infinite sum of time, which is not a real eternity. It stands in the middle between time and eternity: "And by this way can be measured eternal time, which is the middle between eternity and time" (*Et ideo huiusmodi mensurantur aevo, quod est medium inter aeternitatem et tempus*). Time can be a continuum, or be separated into parts of time. Time can be imagined or real. This distinction is different from Augustine's view, which taught that all three kinds of time (past, present, and future) are only representations in the mind and therefore dimensions of it. But similar to Augustine, Aquinas says that there are three kinds of time: the first time is the beginning, the second time is the following time, and the last time is the end of time ("time has a beginning and an end" (*tempus autem habet principium et finem*), and "between two instants, there is a middle time" (*inter quaelibet duo instantia sit tempus medium*). But again, in contrast to Augustine, Aquinas admits that, according to Aristotle, time is a kind of motion. Time can be measured as the number of changes (e.g., dark to bright, night to day) or of motions ("movement, whose measurement is time" (*motus, cuius mensura est tempus*) and "because time is the number of motions" (*quia tempus est numerus motus*). Time serves also to represent a metaphysical, not only a physical, development or motion: as angels come to their nature at once, humans come to theirs eventually, because they have to discover the nature of a human as a creature of God.

Also for moral actions, time is an important indicator. Humankind needs sufficient time in order to act morally (*Tempus autem est una de circumstantiis quae requiruntur ad actus virtutum*). Therefore, nobody can be forced to immoral action by reducing his or her time to act or to react properly.

Within time, there are temporal things that are contingent, not necessary. These temporal things, which are all material things, come into existence and vanish after a certain amount of time. They cannot exist eternally in time. However, in his mainly philosophical work *De aeternitate mundi* (c. 1271), Saint Thomas shows that the universe itself is eternal, because the substance, the "basic material" (*materia prima*), is not made and is eternal. This does not mean that our world in its present concrete existence is eternal, but the world and the universe are eternal in their "basic material" (*materia prima*). With this argument, Saint Thomas wanted to increase the philosophical value of the pagan philosopher Aristotle to Christian theology. According to Aquinas, species are not eternal; they will, like other temporal beings or material things, appear and vanish in time. Without *materia prima,* the universe would have been a serious vacuum, which is, according to Saint Thomas, impossible.

Furthermore, humans cannot end time. According to Christian eschatology, it is only God who is able to fulfill time, when Christ returns and separates the good from the evil. So, God is the creator and the dominator of time. "To Him belongs time and the ages" (*Eius sunt tempora et aeternitas*), as it is written in the Office of the Easter Vigil of the Roman Catholic Church. God is outside of time and he is the timeless, eternal being (*esse*). God is the creator of everything and has never been created. He is and always was, is and will always be, without any changes. God, the Sacred Trinity, is the origin of time and the basic ground of being. Similar to Augustine, it is not sensible for Aquinas to speak of time before Creation.

Saint Thomas Aquinas deeply influenced Christian doctrine. His considerations on the property of time and other related subjects were philosophically and theologically investigated in many books and treatises. With his thoughts, Saint Thomas stands in the tradition of the *philosophia perennis,* the Everlasting or Permanent Philosophy, which has its starting point in the philosophy of Plato and Aristotle.

In the early 20th century, *neo-Thomism* emerged: neo-Thomistic philosophers and theologians kept up Aquinas's thoughts in a very comprehensive way: the French thinker Jacques Maritain (1882–1973), the Jesuit Erich Przywara (1889–1972), and the German philosophers Max Müller (1906–1994) and Josef Pieper (1904–1997), among others, represent Thomistic thought in our present time.

Bruno, Spinoza, and Leibniz

All three thinkers—Bruno, Spinoza, and Leibniz—have a rationalistic approach to the question of God. Giordano Bruno (1548–1600) was a monk and philosopher who presented a daring cosmology. Some of his thoughts were adopted by two other philosophers, Spinoza and Leibniz. Bruno and Spinoza are, in general, pantheists and monists. Leibniz is a monotheistic thinker but not a monist; however, he has a rationalistic method in common with Bruno and Spinoza.

Bruno presumed that the world and God are, in the end, both together, because reality has its origin in the eternal imagination. For Bruno, the universe is infinite and there are an infinite number of beings in the cosmos. The universe is infinite because God as the creator of the cosmos is almighty and infinite. A finite cosmos would be too sharp a contrast to honor an almighty and infinite God. So, both God and the universe are infinite, but within time. In Bruno's opinion, there exist an infinite number of eternal worlds. Also, according to Bruno, it is possible to measure time accurately in our world. Before Bruno, most of the thinkers followed Aristotle, who was convinced that only in the sphere of the fixed stars could there be a correct measurement of time. Time can be measured by motion; Bruno developed a pendulum system that could measure time accurately by the motion of the pendulum. Furthermore, he was against the Ptolemaic geocentric model of the universe. Because of his heretical opinions, Giordano Bruno was condemned to death by the Roman Catholic Church in 1600.

Influenced by Bruno and Descartes (1596–1650), the philosopher Baruch (or Benedict) de Spinoza (1632–1677) was convinced that the substance of nature and of God is the same, as is pointed out in the sentence *deus sive natura* ("God or Nature"). He is therefore an exponent of monism and pantheism. God is natural and living, and cannot be separated from matter. He is within every being. Some presumed that Spinoza was an atheist, because all materialistic things are finite in contrast to God, who is immaterial and eternal. However, the Spinozistic concept of nature is not only materialistic, but also something much more complex. For Spinoza, nature has a divine quality even though it also has material qualities. God is the necessary, eternal, and infinite substance of nature or the universe. It follows that there is only *one* substance in the universe (monism), because God and nature are of the same substance. For this reason, God exists necessarily and, furthermore, he was forced to create the universe because of this monistic union of God and nature. The main structures of the universe are causality and necessity. Beyond space and time, there is only the real existence of beings in the universe. The world exists as an infinite sequence of natural processes throughout time. God exists as the eternal substance, but within endless time.

Gottfried Wilhelm von Leibniz (1646–1716) was a scientist, mathematician, and philosopher. He argued that there is a preestablished harmony in the world that is based on the infinite number of monads that are the nonmaterial elements of reality. The first monad is God, who has created the world as the best of all possible worlds. The evil in the world is thus reduced to a minimum, because God has compared our universe to every other possible universe, and he has decided this world to be the best possible world. The metaphysical, physical, and moral evils that exist have their origin in the imperfect and finite cosmos. God is the eternal reason and necessary being of the finite world. Space and time are not absolute, but relative as parts of the world. God and the universe are not of the same substance. In contrast to Bruno and Spinoza, Leibniz was neither a monist nor a pantheist. Leibniz earned his great reputation posthumously, perhaps most notably in Bertrand Russell's (1872–1970) writings.

Teilhard de Chardin and Whitehead

The French Jesuit priest, paleontologist, and philosopher Pierre Teilhard de Chardin (1881–1951) attempted to reconcile Christianity, especially the Roman Catholic position, with the results of his scientific research into evolution. God is the alpha and the omega point of the evolving universe, so God is outside of time and its dynamic framework. For Teilhard, the omega point is the last stage of the evolving noosphere, at the end of human time. From this point of view, God is not only a spectator of the evolution of the universe, but also its aim and goal. Teilhard, who was present at the discovery of

Peking man in 1923–1927, gave these arguments in his controversial major work, *The Phenomenon of Man*, which was denied publication by the Roman Holy Office during Teilhard's lifetime. Later, Pope John XXIII rehabilitated him, and his work became an influential contribution to the church's position on evolution.

With his dynamic philosophy presented in his book *Process and Reality: An Essay in Cosmology* (1929), the mathematician and later philosopher Alfred North Whitehead (1861–1947) defended theism and represented the starting point for process theology; for Whitehead, the whole universe is in fluent change. Therefore, God as the creator of the universe is also in a fluent process and is not able to predict each process in the universe precisely. God is also understood within the framework of time, and God makes possible the change, growth, and flux of reality. Whitehead's argument defends theism, but God is not almighty. Therefore, Whitehead's position is different from the Judaic and Christian positions. Nevertheless, theologians such as Charles Hartshorne, John B. Cobb, Jr., and David Ray Griffin followed Whitehead and contributed to process theology.

The positions of Teilhard and Whitehead make it clear that, in the 20th century, the distance between God as the timeless being and the universe as a creation within time became less and less, because the Creator and the cosmos are constantly interrelated in an ongoing process of eternal creativity.

God as Creator

The idea of God as the Creator is perhaps the most radical theory of time ever conceived, one that imposes a definite beginning to time, along with an explanation of why this should have happened. Before God there was no time, according to this theory, because God created time when he created all things. Theories of God as Creator often, though not invariably, are accompanied by a complementary theory of God overseeing the end of time as well.

Theories of God as Creator are not the common property of humanity, but are the product of specific trends of thought involving monotheism, or the idea of a single god. In cultures that do not subscribe to monotheist notions of God, there is much less evidence of theories of God as Creator or, if such theories can be found, they are much less significant than in monotheist cultures. Creation accounts are also a relatively late development in the evolution of religious thought.

Asian Traditions

When looking at India, for example, amid all the conflicting interpretations one could read into the Vedas, there is little to support the idea of God as a creator from nothing. Among the many speculations is the admission that maybe even the gods do not know, because they emerged after the universe derived its form. The closest parallel to the word *creation* is the Sanskrit word *Srishti,* or "projection." So when it is said that God created things out of nothing, it is meant that the universe is a projection of God, with the extra understanding that the universe creates itself and falls back into itself, in endless cycles, for all time. Other understandings have this projection as a never-ending process of God realizing himself in the universe.

It is also true that no god in the Hindu pantheon was credited with Creation. Brahma is given such an age that even talk of creating the universe seems a paltry exercise. Hinduism divides time into cycles, called *kalpas.* One kalpa consists of 1,000 cycles of 4,320,000 years, which are made up of 12,000 divine years, each of which lasts 360 solar years. And for Brahma one kalpa equals one day.

Another trend in Indian philosophy known as the Kalavada derives its name from *kala,* which originally meant "right moment" but came to mean "time" itself. *Kala* was used in that sense in the Sanskrit writings, where it took on the mantle of being a fundamental principle of the universe and that existed before all other things. It may be that Kali, one of the avatars of Shiva, is also derived from kala. Kali ("the Black One") is, like time, merciless.

In China there is the tale of Pangu (P'an-Ku in the old spelling) who is the child of *yin* and *yang* and who fashioned the cosmos out of the primeval chaos. But he is not a deity to be worshiped, and neither is he credited with actually creating the universe. Then there is the celestial spirit Tai Sui, who presides over the structure of the year. He is, in fact, president of the Celestial Ministry of Time, a prestigious and highly feared office. Tai Sui was venerated as the deity able to influence human destiny. Astrologers were kept busy analyzing dates for auspicious signs that a new project would meet with Tai Sui's approval. The Yuan dynasty (1280–1368) began the practice of sacrificing to Tai Sui before any momentous project was undertaken.

Western Traditions

Among the Greeks, as well as in the great Eastern civilizations, the universe had always existed and creation stories, where they existed at all, told more of fashioning order out of primeval chaos than of creation ordered from nothing. In the *Timaeus,* Plato portrays God as that which imposes order on a preexistent matter. Finding the universe in a state of "inharmonious and disorderly motion," God "reduced it to order from disorder, as he judged that order was in every way better." The same account is given in Book One of Ovid's *Metamorphoses,* and it has been argued that a similar approach can be found in the Hebrew Bible, in, for instance, Psalm 74:12–17 or 89:9–13.

Aristotle was more specific in denying any primal creation role to the gods. Rather, God was the "prime mover" who "moves" the world. As time is eternal, so change is also eternal, which, in turn requires an eternal overseer of that change. This is the prime mover. It is important not to confuse the prime mover with any notion of a personal God as understood in the Christian tradition. The prime mover is nonmaterial and as such occupies no space. It is not distinct from nature, but is the animating principle within nature. Aristotle's God, being eternal, is the sum total of thoughts and animating principles that transcend temporality.

Even more naturalistic was the account of the universe in Lucretius's masterpiece *De rerum natura* (*On the Nature of the Universe*), which was completed in about 60 BCE. Nothing, Lucretius insisted, not even divine power, can create something out of nothing. It was not the principle of divinity that was being challenged but that of supernaturalism. Elsewhere, Lucretius spoke of a limitless universe with no center and composed of indestructible matter.

Nowhere is the difference between monotheist and other cosmologies more apparent than in the idea that the cosmos is the product of a God that operates in history. It is the monotheistic traditions of Judaism, Christianity, and Islam that have the most elaborate accounts of God as Creator. While various interpretations of biblical creation narratives exist, the most influential has been that of *Creatio ex nihilo,* or "creation out of nothing." The Hebrew Bible begins with the assertion: "In the beginning God created the heaven and the earth." There are, however, two accounts of creation in the first books of Genesis. The earlier account can be found in Genesis 2:4–25 and is attributed to an unnamed source called the Yahwist, or simply J, who wrote in the interests of Judah, probably in the eighth or seventh centuries BCE. The J account differs significantly from the later account, in Genesis 1:1–2:4, which is attributed to P, or the Priest, and probably does not predate the Babylonian Captivity of the 6th century BCE.

The J account gives lip service to the creation of the earth and the heavens and gives greater emphasis to the use made of existing materials, such as bringing rain to fructify the earth and creating man out of the dust of the earth. J begins with dry earth from which water later emerges. The later account reverses this and begins with water as the default condition, out of which land emerges. Among other items, this is evidence of P's closer debt to Mesopotamian mythology, which derived from living in a river lowland, unlike the arid land of Palestine, where J wrote. It is also significant that the earlier J Creation account seems contradictory with man being created first, out of the dust (*adam* from *adamah*) whereas the earlier P account has man being created last, as the pinnacle of creation.

These differences in detail and order are symptomatic of a larger difference in underlying attitude. J's account is more organic and closer to the mythological accounts then prevalent. P's account, for instance, makes sure to credit God with the creation of light, departing from many mythological accounts where light is, along with its sister condition darkness, a primordial element of chaos. P's later account is more abstract and rarefied, and serves to strengthen the case of ecclesiastical authority, whose charge it is to interpret these great themes to the unlettered and stand in as their mediators before God.

None of these distinctions played a major role in Christian creation theology before the 19th century. *Creatio ex nihilo* was decreed orthodox theology at the Council of Nicaea in 325 CE and Saint Augustine developed P's account, accentuating the utter majesty and sufficiency of God in overseeing this creation. Augustine also attacked Greek ideas of time having no beginning and there having been no creation. Those who claimed the world was without beginning and consequently not created by God, he wrote, "are strangely deceived, and rave in the incurable madness of impiety." This remained the standard interpretation for more than one and a half thousand years.

The Qur'an is, if anything, even more insistent on the *Creatio ex nihilo* thesis than the Bible. There is little description or explication beyond a bald assertion of Allah's total, entirely sufficient, and generous-hearted creation. Allah is praised as he who "created the heavens and the earth, and made darkness and light." Moreover, he created it with truth, to serve as a sign for the believers and was not fatigued in any way by this creation. These claims are often made in the context of rebuking those who would doubt or warning those who would disbelieve. The Qur'an is no less anthropocentric than the Bible, with several passages allowing for humanity as the highest point of creation by virtue of most resembling Allah the Merciful. As the actual and inviolate words from Allah, this Qur'anic account is, formally at least, the only acceptable Muslim account of the creation of the world.

Despite all the differences among the Greeks, they agreed that *Creatio ex nihilo* made no sense and that creation meant ordering what was already there, rather than starting from scratch. But the triumph of the *Creatio ex nihilo* doctrine changed all that. It also has several important theological ramifications. First, it serves to heighten the focus on God's awesome power to perform such a feat, and our debt to him. Second, it reinforces the distance between the Creator and his creatures, and that God/Allah did not need to create the universe so as to fulfill Himself, or somehow to bring things to a final resolution, because God/Allah was himself already finally resolved.

Third, it extends his power to being above and beyond time.

Perhaps the most specific rendering of God as Creator is the notorious date given by Archbishop James Ussher in 1617. Working from the genealogies of the Hebrew Bible, Ussher dated the creation of the world to October 23, 4004 BCE, with Adam being created 5 days later. This contradicted the Jewish scholars, who decided that October 7, 3761 BCE, was the more likely date. These attempts to discern a specific date for God's act of creation are the ultimate consequence of assuming the biblical narratives to be literally true accounts of what has happened.

Problems with the science and theology of God as Creator idea reappeared with the great advances in science being made in the 17th century. At the very time Archbishop Ussher was devising his chronology based on the biblical genealogies, Galileo, Giordano Bruno, and Isaac Newton were constructing an altogether new account of the universe. This drastic expansion of the universe, and its orientation away from being Earth-centered to sun-centered, had important consequences for ideas about God.

The most imaginative response at the time was deism, which retained for God the role as Creator but attributed everything that has happened since then to the working of nature. Few of the ideas popularized by the deists were original to them. Instead, they reworked ideas articulated by Lucretius, Cicero, and others, in the light of the new understanding of the universe as envisaged by Newton. Problems with deism soon became apparent, in particular, why its vision of God as Creator was any more acceptable than the conventional accounts it sought to replace. There was also the problem that the god of deism was useless for any normal religious function. Another response was pantheism, which subsumed God in Nature, divinizing the latter and secularizing the former. Pantheism was more corrosive to ideas of God as Creator than deism, although it suffered some of the same intellectual objections.

Some scientists in the 19th century, particularly those of a religious persuasion, argued that, as well as the mystery of creation, there was still so much that was unknown and could be attributed only to God's will. But as successive unknown areas have been opened up and provided with naturalistic explanations, the field of God's sphere of influence has been reduced. This was recognized as a problem and by the end of the 19th century was called the "God of the Gaps."

Among nonscientists another response was to relinquish all thoughts of demonstrating the rational and logical veracity of any God-talk, whether in his capacity as Creator or in any other role. Belief in God, in whatever capacity, was a matter of faith alone, in which reason played no part. Variations on this theme were articulated, at the radical end, by the Danish philosopher Søren Kierkegaard, and in more conservative language, by the Oxford movement and Ultramontane Catholicism. A secular variant was arrived at toward the end of the 19th century in early pragmatism, which argued that disputes over the existence of God and his role as Creator were largely irrelevant and incapable of final resolution. What mattered was the benefit such beliefs conferred on the believer.

The most recent response within the religious world to the advances in scientific understanding of the universe and its origins has also been the most conservative. Fundamentalism is the insistence that what is decreed in the scripture of one's religion is literally true in all respects. Thus, God really is the creator of the universe as outlined in the Bible (or the Qur'an), and whatever inconsistencies in the scriptural accounts are either illusory or the result of an unwillingness to believe the truth with the required degree of faith.

Most people, however, have reconciled themselves to the collapse of traditional accounts of God as Creator. By the beginning of the 21st century the general scientific consensus was that the universe is between 13 and 16 billion years old, and came into existence as a result of the big bang. And that the earth is about 4.5 billion years old and is one of countless planets in an expanding universe of unimaginable proportions. Those who have remained religious believers have been content to see the creation accounts as allegories with poetic rather than normative power. There have also been attempts to equate the big bang with accounts of God the Creator, but without success. As several scientific observers have commented, such a move tends to work only if God is reduced to a series of mathematical equations. Those who do not subscribe to any formal religious system simply take the scientific account as the best available account of how things began.

Gödel, Kurt (1906–1978)

Kurt Gödel was a mathematical logician who is best known for his incompleteness theorem. He also developed a theory of time travel based on Einstein's theory of relativity.

Gödel was born on April 28, 1906, in Brünn, Austria (now known as Brno, Czech Republic), and was baptized as a Lutheran. He began studying physics at the University of Vienna in 1924, but in 1926 he switched to mathematics, in which he excelled. Eventually he settled into the field of mathematical logic, which originated in the work of Gottlob Frege and was more fully developed by David Hilbert, Bertrand Russell, and Alfred North Whitehead.

In 1926, Gödel began participating in the Vienna Circle, a group of mathematicians and philosophers headed by Moritz Schlick. The group's members devoted themselves to propagating logical positivism, the philosophy that all that can be known about nature or reality must be deduced from immediate sensory experience. In spite of his participation, Gödel, like Albert Einstein, would become a lifelong opponent of positivism, arguing that intuition has a proper role to play in science and mathematics. Both he and Einstein rejected the Kantian notion that one can know only the appearances of things and not the things themselves. Because of Gödel's preference for the idealistic philosophies of Plato and Husserl, the philosophical establishment, dominated by the philosophy of Wittgenstein, either ignored or scorned much of his philosophical work.

In 1930, Gödel obtained his Ph.D. In 1931, Gödel published a response to David Hilbert's formalist attempt to develop a system of first principles (or axioms) from which one could apply rules of syntax to derive all the theorems of a mathematical domain. He undermined Hilbert's program by showing that no set of formalist axioms can ever fully capture the complete set of mathematical truths. There will always be some truths about integers, grasped intuitively, that cannot be proved true or false by any fixed set of axioms. He also showed that a system of axioms for arithmetic could not prove its own consistency. His incompleteness theorem (also known as Gödel's proof) ranks with Einstein's theory of relativity and Heisenberg's uncertainty principle as one of the three most revolutionary scientific findings in the 20th century. The recursive functions that he developed as part of this work were later used by Alan Turing and others in the development of the computer.

From 1933 to 1938, he alternated teaching stints between the University of Vienna and the Institute for Advanced Study (IAS) in Princeton, New Jersey. In 1938, he married Adele Porkert, a divorced nightclub performer. They had no children. After being declared fit for German military service, he and his wife emigrated to America in the winter of 1939–1940 by way of Siberia, Japan, and San Francisco, arriving in March at Princeton where he became a temporary member of the IAS. This status was renewed annually until he became a permanent member in 1946. In 1948, he became a citizen of the United States.

Gödel and Einstein became close friends in 1942 and remained so until Einstein's death in 1955. They joined each other in daily half-hour walks to and from the institute, during which they discussed politics, philosophy, and physics. During this time, Gödel's work focused on proving that Georg Cantor's continuum hypothesis (which dealt with the number of points on a line) was consistent with set theory and therefore could not be disproved.

In 1949, Gödel wrote an essay on the connection between the theory of relativity and idealistic philosophy, which was included in a volume in honor of Einstein's 70th birthday. Gödel developed solutions to the field equations of general relativity that resulted in a possible world (called the Gödel universe) whose spacetime structure is warped or curved so extremely as to form a closed, rotating loop. If a spaceship traveled fast enough along one of the continuous time-like paths in this structure, it could travel to the past or to the future. He then concluded that, if one could travel to the past, then time does not exist as an objective reality. Like Parmenides and Kant, he challenged the intuitive understanding of time as a linear ordering of events in which the past no longer exists, the future is yet to exist, and only the present truly exists. In essence, he showed that if relativity theory is true, then time understood as a succession of never-ending "nows" cannot exist as an objective reality.

Einstein was impressed with the results but doubted that physical data would support the existence of such a universe. In fact, lack of evidence for the rotation of the universe suggests that time travel is not possible in the actual universe (unless scientists can figure out how to create wormholes, which are shortcuts between two points in spacetime). Since its publication, the essay has received some attention from those interested in the topic of time travel, but its conclusion that time is an illusion has been largely ignored. In 1992, Stephen Hawking proposed the "chronology protection conjecture" in order to refute Gödel's argument and other theories of time travel. Hawking postulated that the laws of physics rule out the physical possibility of macroscopic bodies carrying information to the past.

In 1951, Gödel was co-recipient with Julian Schwinger of the first Einstein Award and delivered the Gibbs Lecture for the American Mathematical Society. After that, he became increasingly reclusive and isolated. In 1953, he was elected to the National Academy of Sciences and was promoted to professor at IAS. He published his last paper in 1958. During the 1960s, he developed an ontological argument for the existence of God, building on the arguments of his favorite philosopher, Leibniz. He never published it, perhaps for fear of damage to his reputation if his sympathies toward theism became known. He also continued his quest to develop axioms that would settle the continuum hypothesis. In 1975, he was awarded the National Medal of Science.

After Einstein's death, the economist Oskar Morgenstern became Gödel's friend and caretaker. The logician Hao Wang also became a close associate in the closing years of Gödel's life, and after his death Wang published recollections of conversations with Gödel.

Throughout adulthood, Gödel was plagued by depression, hypochondria, anorexia, and paranoia, and his symptoms worsened as he grew older. He retired from the IAS on July 1, 1976. In 1977, Morgenstern's death and his own wife's deteriorating health exacerbated Gödel's mental and physical disorders. He died of self-starvation on January 14, 1978, weighing only 65 pounds, and was buried in Princeton Cemetery. His wife died in 1981.

Goethe, Johann Wolfgang von (1749–1832)

Johann Wolfgang von Goethe was born on August 28, 1749, in Frankfurt am Main, and died on March 22, 1832, in Weimar. After studying law in Leipzig, he worked as a lawyer in Frankfurt and then underwent further practical training at the Court of Appeal (Reichskammergericht) of Wetzlar. Influenced by the Sturm und Drang movement, he wrote dramas and poems such as *Prometheus, Götz von Berlichingen,* and *The Sorrows of Young Werther* (*Die Leiden des Jungen Werthers*). A rough draft of what later became *Faust* goes back to his time in Frankfurt; in this drama, the topic of time has an important role.

In 1775, Karl August, the duke of Weimar, asked Goethe to join his court (*Weimarer Hof*) and work with him as a state representative. In 1786, Goethe made his first visit to Italy, which lasted 2 years and had a significant influence on his life. Of particular importance for him was his becoming familiar with classical works of art and the scientific research he made on the journey. A meeting with Friedrich Schiller in 1794 encouraged Goethe to increase his literary productivity again. He wrote *Xenien, Wilhelm Meister's Apprenticeship* (*Wilhelm Meisters Lehrjahre*), began writing his autobiographical *Poetry and Truth* (*Dichtung und Wahrheit*), and continued working on *Faust.* However, international political events such as the French Revolution and in 1806 the fall of the German Reich deeply influenced Goethe's thinking, as did numerous innovations in science and technology and their consequences for the life of the people. He became one of the central figures of the Weimar classical period (*Weimarer Klassik*).

Faust and the Theme of Time

Since Goethe worked on *Faust* throughout his life, this drama reflects the whole continuum of his research and interests, and also reveals the changes his thinking had undergone. An important aspect of the drama is the question concerning the relationship among human beings, time, and eternity. In the *Prolog im Himmel (Faust I),* Goethe's concept of eternity is conventional and depends on the Christian worldview. This concept changes with the last scene, titled *Bergschluchten (Faust II),* into something transcendental. The connection between the periods past, present, and future plays a particularly important role. Goethe assembles the scenes into an order that is remote from ordinary human perceptions and experiences of time. The meeting and union of Faust and Helena encompasses a period of more than 3,000 years, whereas the story time of *Faust I* comprises less than one year. The union of antiquity and modernity is not only the reason for the break in the structure of time. Timelessness also arises because Helena symbolizes eternal beauty while Faust stands for eternal striving.

Another type of time is the lifetime of Faust. It limits the period of impact concerning the bet he made with Mephistopheles. Only as long as Faust is alive can Mephistopheles try to satisfy his desires with earthly pleasures and thereby give him a feeling of complete contentment. Consequently, in Goethe's *Faust,* three important spheres of time are united: eternity; the union of past, present, and future; and Faust's own lifetime.

Faust's desire to experience the eternal is in sharp contrast to his limited existence as a human being. His aim "to get to know everything" fails. He realizes that the studies of science, the Bible, and magic cannot help him in his endeavors, which is the reason why he abandons them and turns to everyday life. As he grasps that the act and not the word is the beginning of realization, Faust becomes aware of the importance of the present moment.

In his pact with Mephistopheles, Faust is interested in the quality of a certain moment he wishes to experience. The problem is that the two partners in the contract have different opinions about time. Mephistopheles affirms this worldliness and inevitable death, so eternity itself is hostile to him. According to Faust, however, time that passes is hostile, because he sees eternity as a cycle of life, growth, death, and rebirth.

In the pact, Faust demands total fulfillment in one moment. Only then is he ready to give his soul to the devil. Mephistopheles tries to win the bet by offering Faust various types of sensual pleasures, but he underestimates Faust's spiritual nature. It is very convenient for Mephistopheles that Faust seems to reject eternity in favor of the moment; this is because God represents the eternal, while Mephistopheles stands for the single moment. In the beginning, Mephistopheles confronts Faust with the pleasant aspects of life in Auerbach's cellar, trying to cheer him up and ease his thoughtful mind.

Concerning individual pleasure, time is a succession of moments that are not related to one another. Faust's striving in the company of Mephistopheles represents the timeless element in human beings. For Faust, momentary pleasures are not sufficient for complete fulfillment. This seems analogous to the beauty of Helena, which is also timeless because beauty is hidden in the law of nature. Therefore, the union with Helena is important for Faust. Faust's situation begins to change when he recognizes past events as important. He develops a new attitude toward sensual experiences, because in his union with Helena he realized how fulfilling a moment can be. His failure to combine eternal beauty, represented by Helena, with present time leads to the need for significant actions. Act IV of the second part of *Faust* shows Faust's development, his willingness to do things for their own sake. At this point, the dangers and consequences of his activities become clear. The need for power and property (land reclamation) brings with it destruction (of landscapes and buildings) and death (Philemon and Baucis).

The process of acceleration is manifested in Faust as well as Mephistopheles. Faust curses slowness; he is marked by precipitated striving, which is cultivated by Mephistopheles. He forges plans and carries them out quickly (money economy at the emperor's court, draining of the coast to gain land). As a consequence, others are damaged and he destroys himself. Lemurs dig Faust's grave under Mephistopheles' supervision. Faust, as an old, blind man, interprets the noises as a continuation of his project to drain the marshland. In this moment, in a vision of a future, free society, Faust asks, with the words, "Stay, thou art so beautiful!" for the moment to stay. He dies, and the devils come to take his soul. But his immortal soul could be saved.

The polarity of moment and eternity corresponds to Goethe's development from youth to old age. The importance of the moment is a quality associated with the Sturm und Drang movement; classical antiquity, however, offers timelessness and permanence.

For the phenomenon of acceleration, Goethe formed the expression *velozifearisch*. It consists of *velocitas* (hurry) and Luzifer (devil). For Goethe, the acceleration of time is the origin of modernity. Modern civilization, which is characterized by rapidity and acceleration, also affects the mental states, thinking, and acting of modern human beings. Faust values progress and so he becomes restless and unscrupulous; omissions, mistakes, and violence result.

Goethe's Historical Interests

In the field of historical research, which was important to Goethe all his life, the polarity of permanence and fast change plays a significant role. In the early decades of his life, Goethe's historical interest can be found in his dramas *Götz von Berlichingen* and *Egmont*.

During his stays in Italy, Goethe realized nature and art were permanent and reliable because history was present in the antiquities. Back in Weimar, he was caught up in the events of world history and his belief in stability began to fade. He regarded the French Revolution as chaotic and as responsible for accelerating the historical process. Goethe wished to understand events and acted accordingly, but felt helpless. He realized that his own desires could not affect the progress of history, and recognized the arbitrariness and unpredictability of events, which reminded him of natural changes. Looking for stability, he discovered his roots and began his autobiographical work, *Poetry and Truth* (*Dichtung und Wahrheit*). Nonetheless, Goethe continued to place a high value on progress.

Botanical Investigations

The ambiguity between Goethe's interests in progress and his own thoughts on development (metamorphosis) come out clearly and are put into perspective. According to Goethe, time plays an important role in nature. One of his fundamental ideas was the organic development from the simple to the absolute. He believed he recognized a special type of original plant (*Urpflanze*) in every plant. To verify this idea, Goethe undertook biological research during his journeys to Italy and at his home, on his idea of an original plant type.

He looked for something that is common in all plants. This led him to make generalizations different from those of Linné (Linnaeus), who tried to find a classification based on the differences between plants. With his generalizations, Goethe progressed from the original plant to the original leaf (*Urorgan Blatt*). In his opinion, all parts of the plant emerged from this leaf. Two laws are responsible for changes in the plant: A law of nature constructs the plant, and a law of the external circumstances modifies it.

Later, Goethe gave up his idea of an original plant type in favor of the theory of types (*Typus*). He subsequently made his theory of the evolution of plants more general so that it included animals. In contrast to the theory of metamorphosis, his type theory represents a constant in natural biodiversity. Nevertheless, both terms (*Leitbegriffe*) in Goethe's scientific studies are connected and lead to biodiversity. The type sets limits that metamorphosis cannot exceed, though it can shine though as an original principle (*Urprinzip*) because of the creation of organisms brought about by metamorphosis.

The concept of duality of moment (type) and eternity (metamorphosis) are implicit or explicit in Goethe's theoretical writings.

Gospels

The early Christians used the Latin term *evangelium* to refer to the spoken message about Jesus Christ; in Old English, the translation was "god spel" (good tale), which eventually became "Gospel" as a generic label for written narratives of the life, death, and resurrection of Jesus. Four Gospels were accepted into the Christian canon, and around 40 other "apocryphal" Gospels have been identified. The four canonical Gospels were attributed to Matthew, Mark, Luke, and John, and they appear in that order in the Christian canon. Matthew and John were numbered among the 12 disciples of Jesus. Early church tradition associated Mark with Simon Peter, and Luke was an associate of Paul. Scholars generally accept the validity of the early church traditions about the authorship of the Gospels of Mark and Luke, but many are skeptical about the degree to which Matthew and John were responsible for the Gospels associated with their names.

The Gospels bear some similarities with the conventions of ancient biographies, but overall they are unique among ancient writings. As narratives, each Gospel has a beginning, middle, and end, but they do not follow strict chronological order in describing the events of the life of Jesus. Instead, they often group the sayings and deeds of Jesus by theme or topic.

Of the four Gospels, only Matthew and Luke begin their narratives about Jesus by describing his birth. They also include genealogies that describe Jesus' roots in the history of Israel, going back as far as Abraham in the case of Matthew and as far as Adam in the case of Luke. Only Luke describes an event from Jesus' childhood, namely, his visit to the Temple when he was 12 years old.

The first event recorded by Mark and John is the ministry of John the Baptist and his baptism of Jesus. All four Gospels emphasize John's role as a prophet who was preparing God's people for the coming of the Messiah and his kingdom. Immediately after Jesus' baptism, Matthew, Mark, and Luke describe Jesus' temptation by Satan during his 40 days in the wilderness. This initial, decisive confrontation with the forces of evil serves as the overture for his public ministry, during which Jesus repeatedly frees people from the domination of evil by means of healings and exorcisms.

The four Gospels differ in their description of the next events of Jesus' life. Matthew and Mark describe the beginning of his preaching in Galilee and the call of his 12 disciples. Luke also refers to

Jesus' return to Galilee, but then he recounts his sermon in the synagogue in Nazareth. This story serves to introduce important themes developed more fully in the Gospel of Luke and the Acts of the Apostles. After Jesus' baptism by John, the Gospel of John describes Jesus' call of four disciples and the miracle of changing water into wine at the marriage celebration in Cana. After these stories of the beginning of Jesus' ministry, Matthew, Mark, and Luke follow each other closely in terms of content and order. Because of their similarities, they are referred to as the "Synoptic" Gospels, a term that means "to see together." John is significantly different from the other three in both order and content.

All four Gospels describe an event in Jesus' life that serves as the turning point in the narrative. For the Synoptics, this event is Peter's confession of Jesus as Messiah followed by Jesus' first prediction of his suffering, death, and resurrection. That event is followed by the Transfiguration during which the heavenly voice declares that Jesus is God's Son. From then on, each narrative moves inexorably toward Jesus' arrest, trial, and death in Jerusalem. For the Gospel of John, the turning point is associated with Jesus' raising of Lazarus from the dead, an event that crystallized the intention of the Jewish leaders to plot Jesus' death.

All four Gospels contain a lengthy account of the last week of Jesus' life, which is called "the Passion Narrative." This narrative may have existed as a written document before its use by Mark, the first person to write a Gospel. The Passion Narrative begins with Jesus' triumphal entry into Jerusalem on Sunday, continues with various discourses and events that culminate in the Last Supper on Thursday night, and ends with his crucifixion on Friday. All the Gospels conclude with narratives of Jesus' appearances to his disciples after his resurrection on Sunday morning.

The Gospel writers were motivated to write narratives about Jesus because of their conviction that Jesus brought about the beginning of the end of history. Many Jews at that time believed that history would be divided into two parts. This present age, which is dominated by sin and death, would be replaced by the age to come. The event that would usher in the age to come was the Day of the Lord, when the Messiah would establish God's kingly rule on Earth. The resurrection of the dead was associated with the Day of the Lord.

Saint Matthew writing his Gospel under the Inspiration of Christ. From a miniature in a manuscript of the ninth century, in the Burgundian Library, Brussels (drawn by Count H. de Vielcastel).

Christians believed that, through his death and resurrection, Jesus conquered the powers of sin and death and therefore inaugurated the age to come. Because the age to come has broken into the present, the Gospel writers describe the kingdom of God as both present and future. Each Gospel attempted to show how the turning of the ages occurred through Jesus.

The majority view among scholars since the early 1900s is that Mark wrote the first Gospel about 40 years after Jesus' death and that Matthew and Luke used Mark as the framework for their Gospels, which were written 10 to 20 years later. Matthew and Luke supplemented Mark with a written source they had in common, which is called "Q" (from the German *Quelle,* which means "source"). Each included his own distinctive material, which is referred to as "M" and

"L," respectively. A minority of scholars have defended the centuries-old belief that Matthew was the first Gospel. Some have argued against the existence of Q, and some have posited a more complex interaction over time among all the Gospel writers.

Most scholars date the Gospel of John near the end of the first century. The narrative claims to be based on the eyewitness testimony of the Beloved Disciple, who has often been identified with John the son of Zebedee. Various scholars have proposed that the book was revised more than once by different editors. Most would concede that an editor (who was different from the original author or authors) compiled the final version that appears in the Christian canon.

Gosse, Philip Henry (1810–1888)

In the middle of the 19th century there emerged a serious concern about time. Ongoing discoveries in geology, paleontology, and archaeology were challenging the then-held age of our Earth, fixity of species, and recent appearance of the human animal on this planet. Rocks, fossils, and artifacts were suggesting a new worldview, in terms of pervasive change throughout time, far different from the traditional static philosophy of nature. There was a glaring discrepancy between the scientific perspective of naturalists and the biblical framework of religionists. Inevitably, a major conflict developed between facts and beliefs. The empirical evidence for evolution contradicted the story of Genesis: Is the earth millions of years old, or was it divinely created only a few thousand years ago? A resolution seemed to be impossible, especially for those fundamentalists who held to a strict and literal interpretation of the Holy Scriptures.

Philip Henry Gosse made a bold and unusual attempt to reconcile the creationism of revealed religion with the evolutionism of the earth sciences. He was a fundamentalist creationist who belonged to the Plymouth Brethren sect in Victorian England. As such, his acceptance of the Mosaic cosmogony included a rigid adherence to both the sudden creation of Adam and the later Noachian deluge, each of these two events caused by the personal God of Christianity. However, Gosse was also an avid naturalist who could not easily dismiss the overwhelming and compelling factual evidence for organic evolution. Nevertheless, he rejected outright the dynamic concepts and disturbing implications (for him) of the evolutionary perspective. Therefore, his own personal beliefs required that he somehow resolve the contradiction between evolutionist science and fundamentalist religion. Gosse presented his incredible resolution in two books, *Life* (1857) and *Omphalos: An Attempt to Untie the Geological Knot* (1857).

Gosse's bizarre explanation for divine creation gave priority to biblical beliefs and immediate experience, rather than to science and reason. It is an interpretation ultimately based on an essential distinction between two different modes of existence: preternatural or ideal time in the perfect and infinite mind of a personal God prior to the act of creation, and the later natural or real time of objects and events in this material world of ongoing change and evolutionary development. In short, there is a crucial difference between prochronic time and diachronic time. Moreover, Gosse claimed that the course of everything inorganic and organic in nature is a circle.

Gosse firmly held that both the geological column of rock strata and the paleontological record of fossil evidence were suddenly created, all at once, along with the earth's existing plants and animals (including our own species) through the divine act of a personal God. In fact, Gosse further argued that this planet suddenly came into existence as an ongoing world already containing a sequence of fossil remains in a series of rock layers. Consequently, rocks and fossils only suggest both an extensive natural past for the earth itself and a vast evolutionary history for all previous life forms on this planet. Briefly, due to this instant creation with its built-in geological column and fossil record, the earth only appears to be as old as the geopaleontological evidence suggests to the evolutionary naturalists; the stratigraphic layers with their fossil remains were suddenly formed merely to suggest an ancient planet and the process of organic evolution.

According to Gosse, the appearance of our Earth together with its life forms occurred at a specific point, which was the violent irruption of natural time, at the beginning of cosmic reality from ideal time. Gosse thought that the empirical evidence of science is deceptive, and the untold eons of planetary time are simply an illusion. Consequently, he believed that his unique interpretation of creation would allow him to accept the evidence for evolution without accepting the process of evolution.

In a fantastic thought experiment, Gosse imagined himself experiencing plants and animals living on a pristine Earth just after the instant of creation. All of these organisms would appear to him to have had a planetary history but, he argued, in reality, this was not the case. He even claimed that Adam had been suddenly created with a navel so that it would appear as if he had had a natural birth! Furthermore, the observed rock strata and fossil record had been deliberately placed in the earth by God so that our planet would appear to have had a vast evolutionary history. It was a divine scheme to test the biblical faith of fundamentalist believers (or perhaps even to deceive them). For Gosse, the evolutionary naturalists are merely discovering the divinely imprinted evidence for geological history and biological evolution, although each had never occurred; neither geological nor biological changes had taken place over the assumed sweeping eons of planetary time.

Not surprisingly, Gosse's explanation for the creation of our Earth did not convince scientists or philosophers or theologians. Naturalists remained evolutionists, philosophers debated his ideas, and theologians grappled with the startling implications of the earth sciences. Gosse himself was devastated because his serious effort to reconcile science and religion was rejected by both evolutionists and fundamentalists. Ironically, since he believed in an instant creation of everything, his own theistic cosmogony is not compatible with either the biblical 6-day account of Genesis in the Holy Bible or the vast perspectives of modern process theologians.

Gosse's worldview is supported by neither science nor reason. Any fixed date for the sudden moment of divine creation would be arbitrary; in fact, one could argue that all reality (including natural time and our species) is still in the mind of God, with the origin of this material universe yet to take place. Invoking the law of parsimony, one would be wise to accept the temporal frameworks of cosmic evolution and earth history over Gosse's improbable worldview. However, the creation/evolution controversy over time continues, despite the ongoing advances in the special sciences. Gosse's desperate attempt at reconciliation remains an interesting relic of an outmoded religious-oriented cosmogony. A progressive understanding of and appreciation for time requires that one remain open to the continuing discoveries in science and the new perspectives in philosophy.

Grand Canyon

The Grand Canyon, located in Arizona in the United States, is usually regarded as one of the world's seven natural wonders. The canyon, carved by the Colorado River and home to many ecosystems and artifacts, still has scientists wondering exactly how and when it was formed. Each year, nearly 5 million people visit the Grand Canyon.

The canyon is expansive, stretching 277 miles from Lake Powell at the Utah–Arizona border down into Lake Mead, near Las Vegas. The canyon is 6,000 feet at its deepest point and 15 miles across at its widest point.

The wildlife and plant matter found within the Grand Canyon are diverse, attributed in large part to its size, depth, and variation. While the Grand Canyon is very large and wide at some locations, its range of height and size vary along its course and its weather is diverse. Weather varies as much as 5.5 degrees Fahrenheit with each 1,000 foot change in elevation. At certain points, then, the temperature may vary an average of 33 degrees from the upper rim to the river walls. These weather variations allow for the presence of five of the seven life zones and three of the four desert types in North America. The five life zones represented are the Lower Sonoran, Upper Sonoran, Transition, Canadian, and Hudsonian.

The origin of the Grand Canyon is still something of a mystery. Scientists continue to study and hypothesize about its age and origin, but cannot come to a consensus. Despite agreement that the layers of granite at the deepest portions of the gorge are 1.7 billion years old, it is widely accepted that the canyon itself is nowhere near as old.

Modern geologists are puzzled by the seemingly faster erosion in some portions of the canyon than others. This may be explained by the most widely accepted theory of the canyon's formation—the upper sedimentary layers were the base for several small shallow lakes that existed for hundreds of thousands of years. Over time, the rock rose through tectonic forces to create the Colorado plateau. All the while, the Colorado River cut down through the rock, but was thwarted by the harder portions of igneous rock, which now are some of the narrowest portions of the canyon. This whole process was said to have begun about 70 million years ago. Some researchers argue, however, that the landscape of the canyon is far too immature and must be newer than 5 million years old.

Yet another theory suggests that two separate river systems, not lakes, existed and merged to form what is now the Colorado River. They speculate that the westward river absorbed the eastward river in a process called headward erosion. This theory suggests that the headward erosion process would have begun about 15 million years ago.

Some of the most recent research suggests that the gorge may have been carved within the past million years. Scientists suggest that it was only recently that we have understood just how quickly erosion can take place, drastically affecting the timeline of the creation of the canyon.

Although the age of the Grand Canyon remains in dispute, it is home to some of the oldest, most diverse natural elements in the world.

GRIM REAPER

In Western cultures, the Grim Reaper is the most commonly known personification of death. Its current form as a macabre and sinister image has evolved over time, beginning as a feminine figure in the ancient world and transforming into the masculine form in ancient Greek literature. These personifications and images are preserved in art, literature, and film. In the future, the form assumed by this figure will naturally reflect the philosophies, ideologies, and technologies of the culture of the time, and the image of the death guide will reflect the notions of death held by tomorrow's generations. The personified death image may be portrayed as an assistant or travel guide, or it may be a more diabolical instigator, a big brother, or a computer-generated entity that perpetrates the dance of death.

Before the 19th century, the Grim Reaper was more commonly referred to as an Angel of Death. This icon of death was a winged angel that waited to escort the living to their place in the afterlife. The image of this angel was much less menacing and gruesome than today's Grim Reaper, a hooded and cloaked skeleton. The skeleton as a symbol resonates deeply within the human psyche, signifying the importance and the inevitability of death. The Grim Reaper carries a scythe or a sickle, an agricultural instrument that for centuries has been used to cut down and harvest crops. He uses his instruments to harvest or gather the living and take them to their death. Using various disguises such as illness, sudden accidents, and catastrophes, he randomly strikes and unquestioningly takes the lives of young and old, male and female, rich and poor, without discrimination.

The Grim Reaper's modern appearance originates in Greek literature and art, which associates the god Cronus with the passing of time. The god Cronus harvested crops with a sickle, which he later used to castrate his father, Uranus. Cronus later went on to swallow all of his children, except Zeus, out of fear that they might in turn retaliate against him in the same way he had retaliated against his father. Cronus is often seen carrying this scythe, a tool similar to the sickle, and is also depicted with an hourglass in his role as Father Time.

In oral tradition, some similarities between Cronus and the Grim Reaper developed, and that is why we often see the Grim Reaper brandishing the scythe. Sometimes, the Grim Reaper is also seen carrying an hourglass, an image intended to remind us that time never stops and that we are mortal. With each grain of sand that falls, we are moving closer to the end of our time on Earth.

H

Haeckel, Ernst (1834–1919)

Greatly influenced by reading Charles Darwin's *On the Origin of Species,* Ernst Haeckel accepted the fact of evolution and became known as the "Darwin of Germany" for his own extensive researches and copious publications. He had studied medicine, become interested in botany and zoology (especially marine organisms and comparative embryology), and eagerly extended the consequences of evolution to philosophy and theology. His focus on time change included a serious consideration of the origin and history of our species within a cosmic framework.

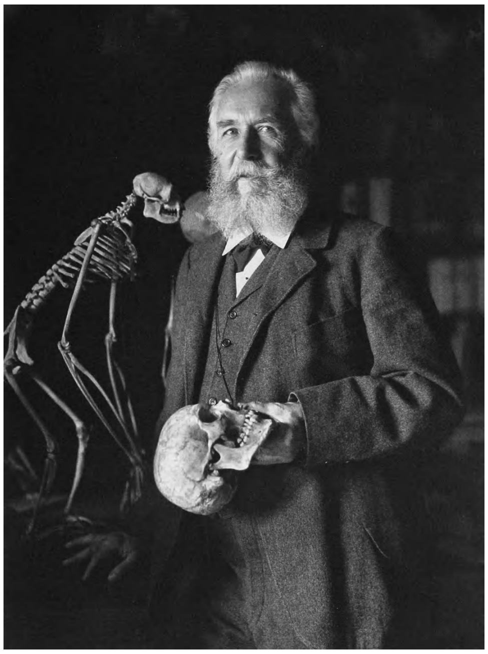
Unlike the cautious Darwin, the bold Haeckel did not hesitate to consider both the philosophical implications and theological ramifications of evolution for understanding this universe in general and appreciating life on Earth in particular. He argued for the essential unity of this dynamic cosmos. His worldview acknowledged the origin of life from matter in the remote past, and then, over eons of time, the enormous diversity of plants and animals that appeared throughout organic history.

Haeckel did not know the true age of this universe or of the earth. He was unaware of the vast durations of time represented by the geologic column of our planet, with its fossil record. Even so, his mind always remained open to those new facts, concepts, and perspectives that were being contributed by the evolutionary sciences. Likewise, Haeckel never hesitated to criticize severely those individuals (particularly religionists) who refused to accept the fact of evolution and its devastating consequences for all earth-bound and human-centered interpretations of reality. For him, cosmic immensity and the probability of life forms and intelligent beings existing elsewhere on other worlds was sufficient reason for doubting that our own species occupies a special place in evolving nature.

Before Darwin had done so, Haeckel wrote that the human animal had emerged from an apelike form. He speculated that Asia was the birthplace of the first hominids, hypothesizing that a now-vanished land mass (Lemuria) had been the geographical location where the evolution of humanlike hominoids from apelike hominoids had occurred. He even gave the scientific name *Pithecanthropus alalus* (ape-man without speech) to this assumed "missing link" between fossil apes and the first humans.

Furthermore, Haeckel argued that our species and the three great apes (orangutan, gorilla, and chimpanzee) differ merely in degree rather than in kind, due to the relatively recent separation of the earliest hominid form from a common ancestor with the fossil apes in terms of evolution. He also claimed that all human biological characteristics and mental activities had slowly evolved from earlier apelike forms. Consequently, our species is a recent product of, and totally within, material nature.

Ernst Haeckel's most popular work is *The Riddle of the Universe,* in which he presented the basic ideas of his evolutionary worldview. For him, God and the universe are the same entity,



One of the principal supporters of Charles Darwin's theories of evolution in Germany, Ernst Haeckel wrote wide-ranging books addressed to the general public, and his illustrations inspired many artists.

with things endlessly becoming and passing away throughout cosmic time. Moreover, as a result of his lifelong studies in comparative morphology, Haeckel himself drew the first tree of life to illustrate the evolutionary relationships among organisms on earth. The fascinating drawings for his scientific publications on evolution and related subjects may still be seen at the Ernst Haeckel House, now a museum in Jena, Germany.

HAMMURABI, CODEX OF

The Codex of Hammurabi is one of the oldest sets of laws in the world. The over-2-meter-long slabs with their engraved laws were created at the behest of Hammurabi (presumably c. 1792–1750 BCE), a significant ruler of the Babylonian dynasty and king of Sumer and Akkad. The Codex offers an early document of human law that is defined by its reference to the past; in other words, to the divine commandments and common customs that paved the way for the legitimacy of legal regulations.

Similar to its predecessors, among which the Codex of Ur-Nammu, the Codex of Lipit-Ishtar, and the Codex of Eshnunna are the best-known examples, the concept of a "codex" is misleading, because, in a modern sense, a codex is understood to be a generally valid legal system whose enforcement is guaranteed by the state. The ancient Oriental codices, however, are incomplete collections of individual legal cases that usually express the will of the lawmaker to reform outdated laws or traditions. This also applies to the Codex of Hammurabi. But it is different from earlier codices in that it aspires to exert a standardized system of law on the entire realm of the given ruler. This was unprecedented in the ancient Orient, where a generally binding common law in accordance with state regulations was still unknown; justice was usually administered by virtue of traditional customs. However, there are contradictory reports about whether Hammurabi's project was successful or not: Some historians assume that the individual paragraphs were actually taken from everyday legal practice because many trial certificates express the same point of view in their verdict as the Codex. Other historians consider the Codex to have been a more theoretical manifesto that was never directly put into practice because, among other things, many of the reported verdicts refer to Hammurabi's regulations, but none of them mention the inscriptions.

Also, similar to earlier collections of law, the Codex of Hammurabi consists of a prologue, laws, and an epilogue. Both the prologue and the epilogue serve to legitimize the text: for example, at the beginning, by showing the symbols of power that Hammurabi receives from the hands of the sun god Shamash; and, at the end, by referring to the social justice of the legal ordinances. The collection itself consists of 282 paragraphs that, in addition to regulating a number of classical criminal and civil law cases, deal with such seemingly modern areas as the law of tenants and landlords, building regulations, and tort laws. From a sociological point of view, these reforms were designed to solve problems that derived from the socioeconomic developments of the 2 centuries prior to the Codex, during which Babylon grew from a fortified settlement to a metropolis on the Euphrates with a complex social and economic structure.

The Codex's principles of justice, the talion law as well as mirror punishment, are of particular importance to the history and philosophy of law: Talion (Latin *talio,* revenge; Greek *talios,* equal) was seen as a legal figure who sought to achieve a balance between the damage done to the victim and the damage that was to be done to the perpetrator. The best-known formula is "an eye for an eye," which also found its way into the Judeo-Christian Bible. Mirror punishment goes beyond the idea of enacting the same action upon the criminal as the criminal perpetrated upon the victim. It also implies punishing the part of the perpetrator's body used to commit the crime (e.g., chopping off the hand of a thief).

These punishments not only seem draconian today, they also seemed to some extent draconian in Hammurabi's era in comparison to more ancient codices, such as the Codex of Eshnunna. The Codex of Hammurabi even permitted the death penalty for minor offenses like theft or libel. Certainly one of Hammurabi's central motives was to employ methods of deterrence to consolidate his empire, which covered a large section of Mesopotamia. Another reason might have been that imprisonment was not really part of the nomadic tradition, which essentially knew no prisons. Nevertheless, the concept of justice expressed in the principle of talion was adapted again and again. A number of paragraphs from the Codex of Hammurabi can also be found elsewhere, for example, in the Bible, which is how the Codex exerted an influence on the Occident's sense of right or wrong.

Harris, Marvin (1927–2001)

Marvin Harris, American anthropologist, was known for his theoretical contributions to the concept of cultural materialism. His theoretical perspective of cultural materialism, though not a unifying theory of culture, sought to explain variations and commonalities among human cultures. As reflected within previous ethnographic research, the development and advancements of various human cultures exhibit many similarities and differences. Amid documenting these cultural characteristics, anthropologists have formulated various theoretical perspectives to account for these cultural aspects. The comparison of cultures, especially in a spatiotemporal framework, has inherited epistemological and teleological problems. These problems are revealed in the paradigm shifts seen within the history of cultural anthropology. Harris understood these philosophical problems and developed a unique approach to, and interpretation of, humankind's cultural material existence.

Harris questioned the theoretical basis for the idea and evaluation of culture. In cultural materialism, he viewed cultural structure and its components in terms of expressed culture (all aspects) within the process of selection. Focusing on infrastructure, structure, and superstructure, the symbiotic relationships provide the basis for cultural stasis, cultural advancements, and diversification. Lacking an ascribed ontology and teleology, this unique perspective encompasses all aspects of time—for example, synchronic and diachronic—within a social and evolutionary framework. Expressed infrastructural differences between etic/emic modes of production and domestic/political economy are believed to be dynamic variants of the superstructure; albeit the stability of the superstructure appears to remain more dependent on the infrastructure. This would be reflected on the rates of change and the appearance of any contradictions seen between infrastructure components and their related superstructure. These structures, when juxtaposed with social hierarchy, provide a sustaining and practical benefit for its members. Although social and economic equality is elusive, social power (which would include empowerment) was stated as one of the selective forces of social dynamics that influence the complex nature of both infrastructure and superstructure.

Human culture is both unique and complex. From sociobiology to postmodernism, the wide range of theoretical constructs was seen by Harris as a set of segmented perspectives that lack a comprehensive view. Though Harris never claimed cultural materialism as a comprehensive accounting of culture, his modified Marxist approach attempted to provide the best explanation for the conditions of human culture. The categories of infrastructure and superstructure are seen to provide the best possible avenues for objective study, although the exact relationship of the parts to the whole is tenuous and unpredictable. The concept of time, in an evolutionary framework, can be depicted as a fluid continuum by which material culture reflects human behavior. In this manner, his theoretical perspective never claimed to be a social manifesto. Harris defended science (with all its limitations) and human dignity and value from the metaphysical implications of contending cultural theories. His theoretical perspective and social awareness had a profound influence on cultural anthropology and the understanding of human nature and culture.

Harrison, John (1693–1776)

John Harrison, born in Foulby, England, became one of the world's most renowned horologists. He won the Board of Longitude Prize for developing a chronometer that could be used aboard ship to measure longitude to within 0.5 degree at the end of a voyage to the West Indies. About 1720 he had designed a timepiece that included a compensating apparatus by using different metals for correcting errors due to variations in the weather. Scientifically speaking, Harrison invented a timepiece that allowed for temperature changes or distortion. The first chronometer, which weighed 65 pounds, was completed and submitted to the Board in 1735 and was tested aboard ship the following year. The accuracy of the chronometer was outstanding, but like many inventions it had its detractors. He then built three more; the fourth, in 1761, more than met the standard for the prize, as did the first one. But it wasn't until 1773 that he was fully compensated by the Board.

Up to the early 18th century, ships and their cargoes, along with the mariners, were at extreme risk between ports of call because of not knowing their exact location. After all, an hourglass is not exactly the best timepiece for determining time at sea. John Harrison might well be called the "father" of time at sea, as his invention of an accurate timepiece was the final link in being able to determine longitude, something Galileo thought would be the most precise method for determining an east–west position. In 1730, John Hadley in England, and Thomas Godfrey in America, working independently, perfected the sextant, which accurately found latitude by "shooting" the sun at noon. Latitude, which is part of the earth's coordinate system for measuring relative location, had been rather easily observed and measured for centuries by determining the sun's angle above the horizon, early on using a cross-staff or back-staff. On a globe, latitude is shown as east–west lines that measure distance or position north–south, while longitude is shown as north–south lines that measure distance or position east–west. The earth makes a full revolution on its axis from west to east every 24 hours, or 15° of longitude each hour, the equivalent of one modern-day time zone.

Knowing one's exact longitude at sea is important for determining a ship's position with respect to land. Shipwrecks due to position miscalculations were so common that a Board of Longitude was organized in England in 1714 for the purpose of awarding the sum of £20,000 to anyone who could develop a method for accurately measuring longitude. John Harrison's contribution to measuring this accurately was a timepiece, known as a chronometer, that could be used at sea with a fair amount of accuracy. The timepiece was tested on a voyage to Jamaica with his son William Harrison on board, in 1761–1762, and determined longitude to within 18 nautical miles. Later, in 1764, the chronometer was tested again during a voyage to Barbados with his son on board. The timepiece performed brilliantly and well within the standard prescribed by the Board of Longitude. The fifth chronometer was used by Captain James Cook during his journey across the Pacific Ocean in 1776, although Cook was killed by Hawai'ians before the voyage was completed.

Hartshorne, Charles (1897–2000)

Charles Hartshorne was one of the 20th century's most distinguished philosophers of religion and metaphysicians. He received his Ph.D. at Harvard University, where he was a student of Alfred North Whitehead. Hartshorne taught at the University of Chicago, at Emory University, and at the University of Texas. His ideas about time were influenced by Charles Sanders Peirce, Alfred North Whitehead, and Henry Bergson, as well as by Edmund Husserl and Martin Heidegger.

Hartshorne rests his philosophy on two bases: Its internal coherence and its adequacy in interpreting the facts of experience. Hartshorne believes that the appeal to observation is the sole possible basis of rational knowledge, which includes the purely mathematical. Therefore, the starting point of one's worldview should be one's daily experiences. The world is full of discontinuities, which are measurable as being greater or lesser. One can see them against a background of continuity, such as the continuity of space, time, and color qualities. Since our direct connection to matter is via sensation, the identity of mind and matter is the clue to the nature of things.

Hartshorne agrees with Baruch Spinoza and Whitehead that the primary physical data are within people. However, there is a veil between us and the "external world," and this veil is physiological. Hartshorne himself calls his philosophy *psychicalism*. This means that his philosophy was not derived from physics, but rather from phenomenological observations of sensations as a special class of feelings. The natural sciences tend to abstract from the mind and experience, even though they are (ultimately) derived from experience. But it is not only science that abstracts; even experiences based on the senses are enormous simplifications of the perceived world. Knowledge is not complete until these abstractions are overcome.

What is given to people has two main forms: previous experience by the same person, and other types of events that are not obvious but nonetheless may still be experiences as well, though not experiences by the same person.

The first form occurs in what we usually call memory; the other in what we call perception—the data that always include events in the series of events that have constituted one's own body.

Experiences are directly conditioned by their immediate data, which temporally precede the occurrence of experiences. They must follow and thus may not occur simultaneously with their data. This one-way dependence is a key to time's arrow and to causality: In contrast to classical determinism—which regards the world as a single, tightly interlocked system in which everything causally implies everything else, backward and forward in time—awareness, as in perception or memory, implies the selective and asymmetrical dependence of experience upon the experienced. In memory and perception the experienced events are temporally prior to the experiences.

This directionality of becoming is lost within classical physics. All conditioning involves the temporal priority of the conditions. The conditions are the data, the directly experienced factors. An experience is never identical with its data. No observation could establish an absolute simultaneity. Our categories are positively applicable only in temporal terms. Determinism destroys the structure of time by negating the asymmetry of becoming. The laws of physics that have given an explanation of time's arrow are stated as statistical approximations. Facts of experience give us direct evidence of the reality of contingency.

What the future distinguishes from the present and the past is that future experiences are characterized by their lack of distinct detail: "The future is in principle a rough blueprint, the past a photograph in full color." But the question must be asked as to whether this asymmetry is essential to time or whether it is merely a fact of human psychology. Hartshorne shows that the "not yet" of the future may have a meaning only for a mind not in full enjoyment of all details of what is to come. The future is that in which full consciousness is lacking. We conceive the unity of the different aspects of time—past, present, and future—in the way illustrated by our experiences of memory and anticipation. Without memory and anticipation, "past" and "future" would be meaningless words.

What is the nature of the relation between the past and the present? One explanation is that the cause is past but the effect is present. The cause is the predecessor of the effect. What, then, is the relation of causality? An objective serial order does not require that there be strictly deterministic causal relations. Whitehead, James, Bergson, Immanuel Kant, and others have all answered David Hume's problem in psychological terms. The simplest positive answer furnished by experience is memory. An objective temporal order is explicable if all reality is some form of experience, with each unit endowed with some form of memory. Hartshorne agrees with Whitehead, who has shown how "extension" as well as temporal succession can be described in psychic terms. For Hartshorne there is a world, a temporal–causal process. Things either intrinsically refer to other things, for example, to past events, or they contain no such internal reference to other things. If there is such reference, then it is at least as if the thing perceived or remembered or felt has existed or even still exists. This means that the world is a temporal–spatial network of events. If there is no such reference, then the world has no real connectedness. There would be no world, no real succession of cause–effect at all. Therefore, either everything must be as if idealism were true, or else as if there were no world, no real temporal–causal system. The subject of experience is a wholeness, which is temporally extended through the "specious present" (James), or the quantum of psychic becoming. Spatially, it is one through the voluminous rather than punctiform character of its perspective, or dynamic relationship with other entities.

Hawking, Stephen (1942–)

Stephen William Hawking, probably the best-known physicist since Albert Einstein, is Lucasian

Professor of Mathematics at Cambridge University. Hawking's work with the more exotic areas of theoretical physics and his best-selling book *A Brief History of Time* have earned him a place in the public eye as well as in his own chosen world of physics. He is best known for his contributions to black hole theory and scientific cosmology.

Physics: The Background

Hawking's ideas of time were influenced by the work of scientists and philosophers over two millennia. Aristotle, for example, made many statements about the arrangement of the universe. The whole world was spherical and finite, he postulated in the 4th century BCE. The earth was at the center of the Aristotelian universe, surrounded by one concentric sphere each for the sun, the moon, Mercury, Mars, Venus, Jupiter, and Saturn, and one sphere for the stars. The outermost sphere, containing the stars, was considered superior to the sphere in which the earth resided, and was supposed to be composed of an element called the ether. This concept of interstellar ether would persist in various forms through the early 20th century. The space occupied by the earth, however, was made of the four classical elements of earth, air, fire, and water. Furthermore, on the surface of the earth, the heavier of two bodies that had the same shape would fall faster. Many of Aristotle's postulates were eventually proved false, but his ideas nevertheless became firmly entrenched in science.

Nicolaus Copernicus, over a millennium later in the early 1500s, made the next great development in astronomy. His theory, based on observation, stated that the earth makes not only one complete rotation on its axis per day (as well as executing a slight wobble around this axis) but also one complete revolution around the sun each year, producing the seasons. The sun was placed uncompromisingly at the center of the universe. The earth took its place among the other planets in orbit around the star, with an orbital period of one year. Copernicus retained the celestial spheres of the Ptolemaic and Aristotelian theories, but he associated a greater orbital radius with a longer planetary year, which necessitated a rearrangement of the five known planets into their proper order.

British theoretical physicist Stephen Hawking, Cambridge University Professor and Fellow, circa 1985.
Source: Getty Images.

Early in the tumultuous 17th century, an Italian scientist named Galileo Galilei was at the heart of a battle over the Copernican model of the universe. With his innovative new telescope, Galileo discovered Venus's phases, Jupiter's four largest moons, sunspots, and the moon's topographical features. Venus was of particular interest, since its phases proved that the planets revolved around the sun. In addition, Galileo's observations showed that not everything must orbit the sun directly. His discoveries were not limited to the heavens; Galileo conducted experiments that yielded the laws of both falling and projected bodies. His legendary experiment of dropping two objects from the Leaning Tower of Pisa is just one example of Galileo's many attempts to explain the universe. Galileo's work, together with that of Johannes Kepler, led directly to the epitome of classical physics that was Sir Isaac Newton's lifework.

Newton, who was born in the same year that Galileo died, tied together many of the loose ends of classical physics with strings of mathematics. He is the generally accepted founder of modern calculus. Newton sought to explain natural philosophy, as physics and chemistry were collectively known at the time, with his mathematics. His early work was with optics, and led to the invention of the reflecting telescope, which caused fewer color anomalies than Galileo's refracting model. He later turned his attention to gravity, recognizing that the same force kept the earth orbiting the sun and made apples fall to the ground. Newton derived a law that explained almost every behavior of gravity. The inverse square law calculates the strength of gravity dependent upon the distance between two objects. Newton used this equation to calculate the attraction in the solar system and to explain both the tides and the moon's motions to a high degree of accuracy. Though many of his equations are still used today, Newton's work was based upon a model of the universe that would soon be radically changed. The picture of a three-dimensional space full of Aristotle's ether, with an absolute measure of time that never warped, was shattered irretrievably by a Swiss patent clerk named Albert Einstein.

Einstein made the biggest step forward in cosmology since Copernicus rearranged the solar system. He united Newton's and Huygens's theories of light and wrote the special theory of relativity. This second development, which at the time was understood by only a few physicists, secured Einstein a permanent place in the history of physics. The cornerstone of the theory of relativity is what Einstein called the principle of equivalence: there is no difference between constant acceleration and gravity. In the classic example, a person in an elevator that is moving through space with a constant acceleration equal to the gravitational force on Earth feels no different than if stationary in the elevator on Earth. From this postulate, Einstein realized that there is no absolute reference frame; every frame of reference is equally valid. Any of these frames can be considered stationary if it moves at a constant velocity, and anything within one of these frames will obey Newton's laws of physics. The same holds for any person moving at a constant velocity relative to another frame of reference. Not only did Einstein change the definitions of movement and rest, he also rewrote gravity. Out of the relativity theories came the image of spacetime, a four-dimensional medium through which everything moves and that can be pulled or folded like fabric. Ether was expelled from scientific thought. Gravity was no longer a force, but a warpage of spacetime. Any object trying to travel along a straight line would get caught in a massive object's gravity-caused spacetime warp and follow the circular or elliptical path made by the warp—in other words, it would orbit the massive object. In his later work, Einstein tried to unite the weak and strong nuclear forces with the electromagnetic force and gravity. He failed, and many scientists, including Hawking, are still trying to accomplish the same feat 50 years later.

Life

Hawking's interest in cosmology had its roots in his early childhood, long before his mathematical and scientific aptitudes emerged around age 14. He always liked controlling things, and he built a great number of models during his childhood. Hawking enjoyed the theoretical work inherent in designing the models. When he was a young man, his mother watched him walk home one night after the streetlights were turned out. He watched the stars, and she sensed that he always would, despite his dislike of observational astronomy.

Much of Hawking's best work has been done in conjunction with Roger Penrose, the eminent mathematician. When Hawking was one of Dennis Sciama's Ph.D. students, the postgraduate group benefited greatly from attending a series of lectures that Penrose had given on singularities, the unpredictable points of infinite density found at the center of black holes. Hawking immediately began applying Penrose's ideas to the entire universe. Later in Hawking's career, he worked directly with Penrose to investigate the big bang singularity.

Childhood and Adolescence

Hawking was born on January 8, 1942, in Oxford to Isobel and Frank Hawking. His father was a medical doctor who specialized in tropical diseases. When he was 8, the Hawkings moved to the small town of St. Albans. Hawking has since described the place as conformist. His family felt out of place and was considered outlandish by their neighbors.

Isobel was an ex-Communist who still had strong left-wing sympathies that she passed on to her oldest son. She liked to travel while her husband was in Africa, and the family visited many exotic places. Hawking modeled himself after his often-absent father.

He entered St. Alban's, an excellent secondary school, at age 10. He was awkward, lisped, and was poor at anything physical. He developed passions for mathematics and classical music. Hawking gained a group of friends similar to himself, considered rather geeky by their peers. They built a basic computer called LUCE, which they programmed to solve addition problems. In their teens, the group experimented with the metaphysical. After attending a lecture that outlined problems with reports of ESP success, Hawking decided that everything metaphysical was either false or had a scientific, rather than supernatural, explanation. He has retained the same view throughout his life.

When picking classes one year, Hawking had a dispute with his father over a mathematics class. Hawking's father considered mathematics to have few career options. However, Frank lost the argument and Hawking continued his study of math. Hawking applied to University College at Oxford, his father's alma mater. At 17, he made it through the grueling admissions exams and interrogation-style interviews, was accepted, and received a scholarship.

College and Postgraduate Study

The first year of college did not go very well for Hawking. He suffered from depression, had few friends, and was bored with the work. At the time, he has said, no one worked especially hard in Oxford. The academic load was light; for an intelligent person, college was easy. Hawking has said he worked, on average, about an hour per day through his 4 years at Oxford. The second year, he joined the rowing team and became popular almost immediately. Social events suddenly opened to him, and Hawking threw himself into the center of college life with gusto. He admits to drinking his fair share and playing many practical jokes. In this spirit, Hawking finished his studies and realized that he had not prepared properly for his final exams. In England, not all college degrees are created equal. A graduate could finish with a first, second, or lower-class degree. The class depended upon the student's grade on the final exams. Hawking's score was on the borderline between a first- and second-class degree, which necessitated that Hawking explain his plans to the college authorities. He did so, received a first-class degree, and entered Cambridge in October 1962.

Fred Hoyle was the most famous cosmologist in Britain in the early 1960s. Hawking applied for his Ph.D. study with Hoyle as his advisor, but Hoyle turned him down, and Hawking received Dennis Sciama instead. Once over his original disappointment, Hawking realized that Sciama was a better and more available advisor than Hoyle was. However, he was depressed again during his first semester. The work was difficult. Hawking had an insufficient grasp of mathematics, and although he could still stumble along with everyone else, he wasn't doing as well as he was used to doing. During this period, he also began having motor problems. In the morning, Hawking had trouble getting his hands to work to tie his shoes. At one point, he fell down a flight of stairs at school and had temporary amnesia. He took an IQ exam to make sure no permanent damage had been done, but the trouble continued.

As soon as Hawking returned home for the holiday break, Isobel noticed his clumsiness. His father thought, naturally, that Hawking had picked up a foreign disease on a trip. Hawking missed the beginning of the next school term because he was in the hospital for tests. He was told that he had an unusual case, but his diagnosis didn't arrive until after he returned to school: amyotrophic lateral sclerosis (ALS), better known as Lou Gehrig's disease. Hawking's prognosis was 2 years. The disease began developing quickly, forcing Hawking to walk with a cane. He spent a good deal of the next few months in his dorm room, deeply depressed.

Paradoxically, however, Hawking's life was about to turn around. At his parents' New Year's Eve party in 1962, he met a young woman named Jane Wilde. The two fell in love quickly, and were soon engaged. Hawking realized that he needed his Ph.D. to support a family. Frank, Hawking's father, went to see Sciama about shortening the time requirements for Hawking's Ph.D., but Sciama refused. He treated Hawking no differently from any of his other students, which greatly endeared him to Hawking. Hawking's fellow students—George Ellis, Brandon Carter, and Martin Rees—became his best friends and later his colleagues. Soon Hawking looked for a suitable thesis project. He became involved in solving some equations for a student of Hoyle's that related to the expansion of the universe. The subject interested him greatly. When, shortly thereafter, he attended Penrose's lectures on singularity theory and applied it to the big bang model of the universe, the two ideas coalesced into what would become Hawking's thesis project. He graduated in 1965, after producing a manifesto on expanding universes, and married Wilde in July.

Work and Marriage

Hawking received a fellowship in Gonville and Caius College at Cambridge, in the Department of Applied Mathematics and Theoretical Physics (DAMTP). The young couple moved to a two-story cottage on Little St. Mary's Lane.

The Hawkings entertained frequently. Hawking is known to all of his friends to be a very gregarious person and a trickster. During the mid-1960s, he cultivated an incredibly intelligent, cranky savant image. Though Hawking was still relatively unknown in the physics community, this image grew, along with his reputation for asking penetrating and sometimes uncomfortable questions at lectures, academic evidence of his love for mischief.

The mid 1960s were a very important time for Hawking. In 1967, his first child, Robert, was born. The next year, Hawking became a staff member of the Institute of Theoretical Astronomy. By that time, the ALS had restricted him to a wheelchair. His second child, Lucy, was born in November of 1970. Four years later he moved the entire family to California to do some work at Caltech. It was a happy time for the Hawkings, especially when, on their return to England, the Royal Society invited Hawking to be inducted as a Fellow. This accolade meant a great deal to him.

When the Hawkings returned from their trip to California, they moved to a larger, one-story house on West Road. Though it was a little farther away from Hawking's office at the DAMTP, the single level made it easier for him to move around. The ALS had worsened again. From 1975–1976, Hawking's work drew steadily more attention, earning him many awards: the Eddington Medal from the Royal Astronomy Society, the Pius XI Medal from the Pontifical Academy of Science, and the Royal Society's Hughes Medal, among others. During the second half of the decade, the popular publicity Hawking received also rose dramatically. More honorary titles and awards piled up, including the Albert Einstein Award in 1978, esteemed more highly among physicists than the Nobel Prize.

However, things were not so rosy on the home front. Hawking's marriage was undergoing continuous stresses. Jane, a devout Roman Catholic, was aggravated by her husband's efforts to explain everything with science. Hawking argued with Jane more than once about the role and designated abilities of a divine Creator. In addition, Jane wanted to pursue her own career, and felt that she was a mere appurtenance to Hawking. These problems eventually led to their divorce in 1990. In the 1970s, however, that was still far in the future, and in 1979 Hawking's last child, Timothy, was born. The same year, Hawking was made the Lucasian Professor of Mathematics, Newton's chair at the University of Cambridge.

At this point, with a new baby and two private school tuitions to pay for, there was a dearth of money. Without telling anyone, Hawking began working on a popular cosmology book, but the dream wouldn't bear fruit for years. In the meantime, more accolades poured in. In 1981, Hawking was knighted a Commander of the British Empire, and four colleges, including Notre Dame and Princeton University, made him an honorary doctor of science the next year. In 1985, he embarked on a world lecture tour and had his portrait hung in England's National Gallery. However, the same summer his voice was silenced forever. One night in July, he choked in his hotel room. He was diagnosed with pneumonia and Jane was told that she would have to allow the doctors to cut a hole in his trachea to insert a breathing device. Hawking would no longer be able to speak, but he would live. She approved the operation. A short time later, Walt Waltosz sent a computer voice synthesizer called the Equalizer to Hawking. With this program installed on a wheelchair-mounted computer, Hawking can deliver lectures and speak more intelligibly than before the tracheotomy, although at the reduced rate of about 10 words per minute.

In 1990, Hawking and Jane divorced, and he moved in with one of his nurses, Elaine Mason. The reports of abuse that circulated shortly after their marriage have been strongly denied by Hawking, who refused to press charges.

Major Ideas

Hawking has had many ideas that, cumulatively, have changed the faces and directions of cosmology and black hole research. The earliest idea, the one that eventually blossomed into his Ph.D. dissertation, was to apply Penrose's singularity theory to the universe. An offshoot of this concept was the proof, accomplished with Penrose's help, that the big bang was a naked singularity at the beginning of time. At the time, big bang cosmology contended with Hoyle's pet theory of a "steady-state" universe, which did not recognize an expanding and evolving universe from a cosmic point of origin billions of years ago. Hawking no longer agrees with this steady-state hypothesis or his earlier big bang theory. Instead, he now proposes his own "no-boundaries" theorem, which implies a finite universe without a beginning in time before the big bang. This theorem has had an important impact on cosmology, helping to eliminate the steady-state concept altogether.

Hawking also realized, getting into bed one night in 1970, that the event horizon of a black hole does not shrink, but grows with all matter that enters it. His most famous discovery, Hawking radiation, led from this idea. The result of a 1973 argument with a graduate student about entropy also helped Hawking formulate this discovery. The corollary of Hawking's nocturnal epiphany was the surprising fact that black holes, known for dragging everything in their vicinity past the "point of no return," actually emit particles. Hawking also developed the concept of "mini-holes," tiny black holes that can form only in certain conditions and that radiate massive amounts of energy.

More recently, Hawking has taken Richard Feynman's method of finding the most likely path of a particle in quantum physics, known as the "sum-over-histories" or "path integral" approach, and applied it to the entire universe. This groundbreaking concept led to his no-boundaries theorem, developed in the early 1980s, which states that the big bang did not have a spacetime singularity, and neither will a potential big crunch scenario. Hawking is still working at Cambridge, further developing this concept and that of imaginary time.

Publications

Over the almost 5 decades that Hawking has been researching cosmology and black holes, he has published half a dozen important works. Only one of these, *A Brief History of Time,* has found an audience outside theoretical physicists. The first major paper he wrote, "Singularities and the Geometry of Spacetime," was in conjunction with Penrose. It won the duo the Adams Prize in 1966, when Penrose was working for Birkbeck College. This paper detailed their work on the singularity theorems.

Five years later, Hawking was in print again, this time with fellow Sciama student, George Ellis. *The Large Scale Structure of Spacetime* built on this work, giving a description of the general theory of relativity and then explaining the importance of spacetime curvature. Singularities were explained through the structure of spacetime, and proven to be unavoidable in black holes and at the big bang.

General Relativity: An Einstein Centenary Survey, published in 1979 with Werner Israel, was written as a tribute to one of the greatest scientists of the 20th century. It gave an overview of what had been accomplished with Einstein's mathematical brainchild, the general theory of relativity.

Hawking coauthored and coedited *Superspace and Supergravity* with M. Roček. This compilation of essays, published in the United States in 1981, covered the then-current attempts to create the unified field theory, the set of mathematical formulae that would explain every physical phenomenon. This effort has been foiled every time by nonsensical answers produced when the equations for quantum theory and relativity are combined.

The next year Hawking published *The Very Early Universe,* which covered what was then known about the big bang and the moments shortly thereafter.

His most famous publication, *A Brief History of Time,* was published in spring 1988. Hawking's usual publisher, Cambridge University Press, offered him the largest book deal in their history, 10,000 British pounds. Hawking, however, insisted upon more money and instead accepted Bantam's bid of 250,000 American dollars. Manuscript editing began, and problems arose. After learning to be concise so he could communicate more rapidly using the Equalizer, Hawking needed to use many more words to explain his work to laypeople. Eventually, the book was deemed readable. In the meantime, other countries' offers were pouring in: Germany, Japan, China, Russia, and half a dozen others. Bookstores immediately sold out upon *A Brief History of Time*'s release. Five hundred thousand copies had been sold by summer. It remained on the *New York Times'* best-seller list for 53 weeks, and on the *Sunday Times of London*'s for more than 200 weeks. Soon producers were clamoring for film rights, and a documentary, also called *A Brief History of Time,* was released in 1991.

The following sections review Hawking's work and ideas in greater detail.

The Work

Black Holes

Around the time when Hawking began working in the field of theoretical physics, many things that are now well known had yet to be discovered. White dwarf stars—small, brightly burning remnants of stars like the sun—had been observed, but anything denser than these objects was considered impossible. Quantum theory predicted neutron stars, but since most of these are dim, their existence had not been verified. Theoretically, black holes were known to form at around three solar masses, and physicists believed that one of these exotic phenomena would bend spacetime completely around itself.

Hawking's first research project was on black holes, and as soon as he received his Ph.D., he and Penrose began work on finding out more about singularities. They proved mathematically that in our spacetime, certain situations necessitate singularities. At the time, these were considered to be a glitch in Einstein's theory of relativity and even more absurd than black holes. Hawking and Penrose's breakthrough work gave the proof. Penrose's mathematical method was a perfect match for Hawking's understanding and physical applications.

In the 1960s, Hawking helped establish the theory of black holes and brought them out of the realm of science fiction. Penrose had already proved that a black hole could not form without a singularity at its heart, but the entire concept still garnered skepticism until 1973. That year, the new field of X-ray astronomy turned up Cygnus X-1, an X-ray source that has a 95% probability of being a black hole, according to Hawking.

In 1970, Hawking turned his attention to the event horizon of a black hole. The event horizon is defined as the point where all of the trapped light rays that almost escaped hover, also known as the point of no return for incoming matter. Hawking realized that singularity theory could be applied to black holes. An American graduate student, Jacob Bekenstein, published an article claiming that a black hole's entropy, its measure of disorder, was the same as its event horizon. Hawking was horrified; a black hole couldn't have entropy. According to the second law of thermodynamics, the entropy of the universe should increase with time. Hawking, however, thought entropy around a black hole decreases because the black hole swallows disordered matter, leaving nearby space more orderly. When he tried to prove that Bekenstein was wrong, Hawking instead proved the student partially right. This discovery became known as Hawking radiation. The entropy of a black hole is proportional to its surface area, defined by the event horizon. Furthermore, this area can never decrease, but only increase as matter and energy fall inward. These two ideas, Hawking radiation and the increasing event horizon, were major advances in black hole theory.

Hawking radiation is, simply, the radiation that a black hole emits. This radiation adds disorder to the universe at a rate that perfectly maintains the second law of thermodynamics. It can be described by visualizing a particle and its antiparticle, for instance, an electron and a positron. The particle pair comes into existence by borrowing some of the immense stored energy in the black hole and converting it to matter. Such particles are known as virtual pairs, because they are born and annihilate each other so fast that one cannot detect their existence directly. These pairs turn up very close to the horizon, and one particle is pulled away from the other by the hole's gravity.

This pulling channels more of the black hole's energy into the particle that escapes while the other falls into the hole. The escaping particle therefore appears to have been emitted by the hole, and carries part of the hole's mass away with it. Hawking found that in this manner a black hole would, over eons, lose its mass at an accelerated rate, until it became so small that it exploded, spraying radiation in every direction. Hawking was sure his calculations were wrong, but was convinced otherwise by Penrose and Sciama. Upon further investigation, Hawking found that the temperature of a black hole depends inversely upon its mass, and the higher the temperature, the sooner the hole would explode.

History of the Universe

The origin of the universe was not generally considered in the realm of science until the 1950s. The big bang had been predicted through Einstein's equations, and physicist Alexander Friedmann had even calculated the three universes allowed by Einstein's equations. Einstein tried his best to discredit these ideas, preferring the idea of the "cosmic egg," an immense atom-like mass that exploded, releasing the universe's matter. On the whole, however, the subject was merely ignored.

The big bang was, in fact, given its name by its most famous opponent, Fred Hoyle. He proposed the so-called steady-state hypothesis in which the universe expanded very slightly and had no temporal origin or end. The big bang was a label born of sarcasm. However, the name stuck, and Hawking's doctoral thesis proved several problems with the steady-state concept, soon to be discarded entirely. During his work with Penrose from 1965 to 1970, Hawking helped to prove that the big bang had a singularity from which the entire universe expanded, and that the potential big crunch would also have a similar structure.

In 1975, Hawking focused solely on the big bang. During the previous year, he had met his next set of colleagues at Caltech: Kip Thorne and Don Page. Years before, George Gamow, Ralph Alpher, and Robert Herman made predictions for a ubiquitous radiation background left over from the big bang. In 1965, Arno Penzias and Robert Wilson discovered it. The anticipated temperature, about 2.73° Kelvin, and wavelength, microwave range, were confirmed. The background radiation prediction was a success that helped secure the position of the big bang theory. Hawking probed ever farther back, trying to understand the moment of the big bang itself, the point at which time started. Due to the geometry of the big bang, there is no time before the event, and no one can discover what happened before the Planck time, about 10^{-43} seconds. Hawking kept trying, though, and created a more densely populated view of the early universe than previous scientists did. Cosmologists before Hawking, including Hoyle, had described the conditions and time frame that produced the most abundant elements in the universe: hydrogen, helium, and deuterium. These are the elements that stars burn for fuel, creating the heavier elements, like carbon, by nuclear fusion. However, the image of the first few hours and years after the big bang was a picture of radiation and atomic nuclei floating in an evenly distributed, hot morass of expanding space.

Hawking did not like this picture; if everything was evenly distributed, how did galaxies and stars form in the first place? There was some amount of irregularity, he decided, and was vindicated with the discovery of discrepancies in some areas of the background radiation. Hawking drove farther: If there were irregularities, there would be greater gravity in certain areas. These extremely pressurized areas might create unusually tiny black holes that evaporate quickly when compared to their contemporary stellar counterparts. These should still exist, and some might be exploding close enough for us to detect their gamma ray death throes. Unfortunately, most gamma ray bursts detected have been explained using more standard descriptions than Hawking's mini-holes.

Hawking decided to find out how likely the universe is; literally, what the probability was of the universe developing this way. The only way to deduce this was to consider the entire universe to be one body, the same way that an atom or a proton is considered one unit. To accomplish this calculation, Hawking utilized Richard Feynman's quantum sum-over-histories or path integral approach. This involves calculating all of the paths that a particle can take to get from point A to point Z, and each path's probability. Very different paths usually cancel each other out, leaving a few similar, highly probable choices. That is exactly what happened when Hawking used the path integral for the universe. Working together with Jim Hartle, the duo discovered that a finite universe with no boundaries is one of the most likely types. The easiest way to understand the no-boundaries theory is to think of the earth, which is finite yet has no edges. Hawking was also able to eliminate the big bang singularity by introducing the idea of imaginary time, where the singularity can be thought of as the earth's North pole. The earth grows in circumference from this ordinary point, like the universe did from the big bang. The earth also comes back to one point at the South pole, which represents the potential situation of the universe collapsing into a big crunch state. Hawking discovered, furthermore, that time would not reverse in the big crunch. This universe is completely self-contained, and time always moves forward.

Hawking presented his idea at a Vatican scientific conference. He still could not see back to the very beginning, but there was other progress. Quantum theory stated that the density of the original state was not infinite, which would help to explain the irregularities in the early universe; if the density had been infinite, there would have been no room for density variations.

The "chaotic inflation" concept also developed around this time. It states that there is an infinite universe beyond the boundaries of this one, with areas that are expanding and contracting. Some of these areas grow into their own universes. Alan Guth created the original inflation hypothesis, proposing that the universe is very uniform and its curvature nearly flat because it expanded from an extremely small, unstable state to a softball-sized stable state at a high velocity. Hawking vigorously defends both theories.

Hawking's impact on modern cosmology cannot be overstated. He was instrumental in bringing black holes into the light of physical investigation to be considered seriously and, eventually, discovered. He has also given the physics community new tools and insights into the origin and history of the universe. In addition, Hawking has provided a union of important facets of relativity and quantum theory. Outside of his own direct research, he has also brought many of the obscure concepts and near-incomprehensible methods down to the level of the layperson, making the universe a little more accessible to the public.

In fact, social work is one of the areas where Hawking has used his celebrity most. Hawking has lent support and help multiple times to disabled people in battles against various agencies for heightened accessibility. The social and political awareness that Isobel instilled in her son has flowered in his crusades, where he is using his popularity to bring about change.

Ideas and Beliefs

Cosmological

Hawking has never been a person to leave others in doubt about his opinions, especially concerning cosmology. He believes that his no-boundaries theory is the beginning of the complete union of the titans of physics: relativity and quantum theory. Hawking is confident that the answers to all of the questions humans have ever asked about the universe will be found mathematically, and most likely in the near future. He dislikes the anthropic principle's explanation of all phenomena: Simply put, that everything is how humans observe it because if it was different, there would be no humans to observe it. Hawking wants solid, scientific answers to questions. Therefore, he has put his support behind the superstring theory, hoping that the final results of its calculations are as promising as those already known. However, he is reticent to believe in the extra, submicroscopic dimensions that string theories necessitate.

Hawking has also revised some of his earlier conjectures and discussed some exotic topics more closely associated with science fiction than with physics. He now thinks that mini-holes may be less common than he previously believed. He is also considering the possibility that when a black hole gets very small near the end of its life, it may just disappear from its region of the universe, removing its singularity as well. On the subject of determinism, Hawking thinks everything is probably determined, but no one can ever find out if it is. His opinion of time travel is thoroughly scientific. Since the uncertainty of the position and velocity of particles inherent in quantum physics can never be eliminated, quantum fluctuations would most likely destroy the tiny, opening wormhole necessary for time travel. Furthermore, if surrounding particles could travel through the wormhole, they would begin an ever-accelerating loop that would result in radiation too strong for any human to survive passing through. Hawking has called these ideas his "chronology protection conjecture," an answer to the potential time causality problems produced by time travel.

Social

Hawking's social conscientiousness is often found in his work as well as in his outside activism. An explanation of every question should be attempted, he asserts, no matter how daunting or controversial the subject is. No topic should be consigned to metaphysics or religion, in his opinion. The universe should always be under inspection until humanity as a whole understands everything, and this search for information should be conducted freely, without derision on the part of anyone else. Without passing judgment on the subject, Hawking also asserts that human engineering, with great advances in the capacity for knowledge, will occur very soon despite all efforts to stop it. Directed engineering, he states, will overtake evolution. Eventually, in Hawking's opinion, humans will acquire enough wisdom to stop blowing themselves up, avoiding the complete destruction of the human species.

There are many things that Hawking does not believe in, as well. For instance, he avers that no civilization, regardless of where it is or how advanced it is, will ever be able to control the entire universe. In addition, he doesn't believe that any alien civilization has visited Earth.

When discussing religion, Hawking can be extremely ambiguous. He has stated his belief to be that if a Creator does exist, there was a limited number of ways that the universe, initiated by this figure, could have evolved, regardless of that Being's wishes. Hawking strongly advocates the viewpoint that no question should be left to religion. Yet in Hawking's books there are multiple mentions of God, discussing his powers, knowledge, and role in the universe.

Conclusion

Stephen Hawking still works in his little office in the DAMTP at Cambridge. He oversees a few Ph.D. students and runs the relativity group. However, Hawking is largely free to work on his research. He is still pursuing his concepts of imaginary time and the no-boundary universe as the tools to find final cosmological answers.

Hawking's contributions to physics are frequently ranked with the findings of Newton and Einstein. He has discovered many of the main features of black holes, partially united the theories of quantum mechanics and relativity, and proved enough of his work to win widespread recognition of black holes and singularities as real phenomena. Added to these accomplishments, he has managed to popularize a difficult area of science and developed new methods with which to analyze the beginning of the universe. The most productive era of Hawking's work was several decades ago, but he has not retired yet.

Several areas that Hawking has been involved in are among the most widely investigated new sectors of research. Superstring theory has been gaining popularity since the 1980s, and may hold answers to the remaining unanswered cosmological questions. In string theory, the universe contains 11 dimensions—more or fewer depending upon which of the six interconnected theories one considers. What were particles and waves have been reconfigured into one-dimensional loops or strings of pure energy, so tiny that no equipment available can detect their shape. This theory has shown promise, but it is still being constructed and so cannot be used for all situations.

The short gamma ray bursts that Hawking had hoped would prove the existence of mini-holes are still something of a mystery. Most of these radiation events have been identified as colliding neutron stars, but recent reports of slightly longer bursts, in the range of a few seconds to almost 2 minutes long, cannot be explained so easily.

Gravitational waves, which are formed from the fabric of spacetime and, theoretically, ripple outward from colliding black holes, have been studied theoretically for some time. However, there is no concrete evidence to validate their existence. The subject has experienced a recent revival of interest, and the range of error in the calculations is down to about 20%.

Healing

Healing is the act of repairing or mending, be it tangible or intangible, visible or invisible, over a period of time, whether so lengthy as to be imperceptibly slow or so brief as to appear instantaneous. Time is a key ingredient in any healing, as this process does not in fact occur instantaneously. Rather, in many cases one needs patience to wait for time to pass before the healing reaches its completion or even until the healing had progressed sufficiently to be observed. There is rarely a set time for healing to be completed; rather, one knows when the healing is completed only by the lack of further change taking place.

Healing, whether physical or emotional, is a change; change cannot occur without the passage of time. The passage of time can be measured by the progress seen in the healing—be it a scar forming, bleeding stopping, or a bone knitting itself back together. Although healing can seem like a reversal of time, changing something back to how it once was, in reality it is, of course, always changing to new.

Emotional healing can be harder to perceive, involving as it does the intangible, the unseen, such as the healing of a broken heart or the healing after the death of a loved one. Because the changes in emotional healing are not as easily seen or measured as in the case of physical healing, one may lose track of the progress toward healing at any point on the path the healing has already taken. Such healing may involve rituals that themselves take time, and through these time-based rituals, such as the Catholic anniversary mass or the Jewish kaddish on the anniversary of death, the healing is aided. This time-oriented set of rituals helps with healing that which cannot often be healed through medicine. Time in its sacred aspects is commonly identified with regeneration and renewal.

Heartbeat

The heart is the muscular organ responsible for circulating blood through the body. The average animal heart will beat several billion times throughout life. The human heart, for example, will beat approximately 2.8 billion times over 75 years at 72 beats per minute. The rate at which the human heart beats is controlled by many different factors. The central nervous system controls heart rate with the medulla oblongata. Activation of the parasympathetic nervous system, using the vagus nerve, causes a decrease in heart rate, while activation of the sympathetic nervous system produces an increase in the rate at which the heart beats. The endocrine system controls the heartbeat with hormones, such as epinephrine (adrenaline), which increases heart rate.

Generally, the size of an animal will correlate with how many times its heart will beat in a minute. Smaller animals tend to have a higher resting heart rate, such as the mouse with a heart rate around 500 beats per minute. Larger animals, like the whale or elephant, tend to have a lower resting heart rate, roughly around 20 and 35 beats per minute, respectively. During times of hibernation, the heartbeat in some animals can drop to rates drastically lower than while not hibernating. During summer months, a black bear has a heart rate between 40 and 50 beats per minute. While hibernating, this can slow to as few as 8 beats per minute.

The embryonic heart in humans begins to beat around 3 weeks after conception, at which time it beats at around 75 beats per minute, a rate near the mother's. It then increases linearly to over 170 beats per minute, peaking 7 weeks after conception. The heart rate then decreases to around 145 beats per minute by the 13th week, where it remains until birth. Heart rate remains high throughout childhood, usually not becoming 70 beats per minute until after adolescence.

Young children are often born with heart murmurs. Although these can indicate a defective heart valve, most heart murmurs are from a more benign cause, a patent foramen ovale (PFO). This is an incomplete closure of the wall between the two atria that closes over time as part of normal neonatal development. If a PFO fails to close, as it does in between 20% to 25% of persons, and persists through adulthood, it can increase risk of stroke. This is because minute blood clots in the deoxygenated blood from the peripheral tissues can bypass the lungs, where they are normally filtered out by the microvasculature of the lungs, and pass through the hole between the two atria. These small aggregates can then find their way to the brain and block blood flow. The result can be either a stroke or a transient ischemic attack (TIA), also know as a mini-stroke.

Blood carries oxygen from the lungs to the peripheral tissues and transports nutrients, hormones, and white blood cells. It also aids in waste removal. By beating, the heart is able to pump blood continuously. The rhythmic contractions of the atria and ventricles occur in a synchronized sequence that ensures efficient blood flow. A single heartbeat begins as the result of a spontaneous, rapid depolarization of the pacemaker cells located in the sinoatrial node on the right atrium of the heart. This generates a stimulus for contraction. Pacemaker cells in humans depolarize 70–80 times per minute, resulting in a heart rate of 70–80 beats per minute.

Modern technology has developed artificial pacemakers for patients who suffer from heart problems in which either the natural pacemaker cells in the sinoatrial node do not signal at a high enough rate, or they fail to transmit a stimulus for contraction altogether. The small electronic device is surgically inserted into the chest and connected to the heart with electrodes. The electrodes send electrical impulses to the heart, stimulating each heartbeat. More advanced artificial pacemakers can even control the rate of the electrical impulses, increasing heart rate during physical exertion and decreasing it during times of rest and sleep.

In the late 1960s and early 1970s, around the same time that artificial pacemakers were being successfully implanted and becoming more reliable, the first artificial hearts were being created. Designed by Domingo Liotta, the first artificial heart was successfully implanted in 1969 by surgeon Denton Cooley, although it was used for only a short period of time until a donor heart became available. The Jarvik-7, designed by Robert Jarvik, was used in about 90 patients as a permanent heart replacement before the practice became banned because of the low survival rate of its recipients. Although most patients lived less than a year with the Jarvik-7 as a permanent replacement, it was still used as a temporary device for patients waiting for donor hearts to become available for transplant. In 2004, CardioWest's temporary Total Artificial Heart (TAH-t) was approved by the Food and Drug Administration, the first implantable artificial heart to receive FDA approval. Developed from the Jarvik-7, it is used only to extend life in patients awaiting heart transplant surgery. One patient lived almost one full year with the TAH-t before receiving a donor heart. Over 75% of patients that receive the TAH-t survive through and after the following human donor transplant surgery, most over 5 years.

As the heart ages over time, it can suffer from an array of diseases that ultimately lead to death. Some diseases can be fatal in a very short time; others can take several years until the heart fails. Coronary heart disease is the result of the buildup of plaque in the arteries that supply oxygen to the heart muscle. This occurs over an extended period, sometimes decades. When the plaque then ruptures, the blood forms clots on the plaque and blocks the passage of blood to the heart tissue. Without oxygen it takes only minutes for the heart tissue cells to begin to die and the heartbeat to stop. This is called a myocardial infarction, or heart attack. The heart can also fail as the result of infection by bacteria or a virus. Even poor diet, hypertension, high cholesterol, and structural defects can affect heartbeat and shorten the lifespan of the heart. Although it is possible to survive for prolonged periods of time with some heart diseases, it generally takes only minutes for oxygen-deprived tissues in the heart to die and the heartbeat to stop.

Heat Death, Cosmic

The cosmic heat death of the universe is a prediction that, as everything tends to move from order to chaos, the universe will eventually "run down" like an old clock. The second law of thermodynamics states that entropy tends to increase in an isolated system. The arrow of time points to the fact that all heat in the universe will die eventually. This is borne out by the everyday observation that things tend to move from a higher energy state to a lower energy state. High energy states can also be manifested as more highly organized collections of atoms. Any solid will gradually disperse over time. Given enough time, even all the atoms of the universe will break down.

As various physical phenomena have been studied and understood it has become apparent that over time everything moves to this lower-energy, more dispersed state. From the universe's first moments as a single high-energy point of all matter, it is moving toward dispersal as the energy that binds everything runs down. Scientists currently believe we live in an open universe and that everything will continue over time to expand infinitely in all directions. According to current understandings of particle physics and cosmology, in around 10^{100} years the universe will move to a low-energy, steady state of photons and leptons, dispersed through infinite space.

The death will happen in three phases. First the universe will become dark as the stars go out. The death will follow the pattern of increasing entropy as the energy level and matter density of the universe drop to a level at which galaxies and stars cease to form, around 10 to 100 trillion years from now. Some 14 trillion years after that, the last of the long-lived stars (red dwarves) will go out.

The second phase will be the decay of the complex structure of the material universe. At a point some 10^{14} (1,000 trillion) years from now, the visible structure of the universe will begin to degenerate at its lower levels; planets will begin to decay as they leave their orbits as the result of an accumulated weakening of the gravitational force. These changes will be followed approximately 10^{15} years later by degeneration at the highest levels; galaxies will begin to decay as stars leave their orbits. The final level of visible structural disorder will not take place until around 10^{40} years in the future when matter itself begins to break down. All matter is made of elementary particles, chiefly protons, neutrons, and electrons in various combinations. The predicted half-life of protons is 10^{36} years, which means that by 10^{40} years from now virtually no protons will exist.

The last phases of the universe will be visible only at the subatomic level. When more than 10^{100} years have passed, the last remaining macroscopic structures will disappear as the last black holes evaporate into photons and leptons. The universe will be at an absolute minimum temperature and a featureless sea of subatomic particles subject only to random quantum fluctuations.

Hegel, Georg Wilhelm Friedrich (1770–1831)

German philosopher Georg Wilhelm Friedrich Hegel (1770–1831). A professor at Heidelberg (1816–1818) and Berlin (1818–1831), he differed with Immanuel Kant in allowing that mankind possessed absolute knowledge. He influenced Karl Marx and the existentialists.

Source: Library of Congress, Prints & Photographs Division, LC-USZ62–130772.

The philosopher Georg Wilhelm Friedrich Hegel was born in Stuttgart, Germany, and educated there and in Tubingen. Along with Schelling and Fichte, he was one of the prime exponents of German Idealism. Over the course of a distinguished academic career, Hegel held positions at several universities including Jena, Heidelberg, and Berlin, and through his teaching and his published works became one of the most influential thinkers in the history of Western philosophy.

Hegel's Analysis of Time

Nature and Spirit

In his first essays, written in his youth, Hegel defines time in an essentially negative way, as a destiny hostile to human beings, or as a finite reality intended to be transcended by reason in the eternal knowledge of Ideas. Directly following the Platonic tradition, time is deprecated in order to give greater importance to eternity. It was only later, during the years 1803–1806, that Hegel developed a positive conception of time in the successive preliminary sketches of his philosophy of nature, which are marked by the major discovery of the *dialectic of time*. Hegel considered that time as such, in its original springing forth, has to be understood as an immemorial element of Nature, which is not yet transformed, neither by language nor by memory, into the time proper to the Spirit, history. Nature is the opposite of Spirit, Absolute Spirit as the other of itself, or the hidden Spirit. As being-other than the Spirit, Nature maintains a double relationship with the latter. It is opposed to it as it is its negative, the *being-other* than the Spirit. But at the same time, it has a hidden relationship of identity with Spirit, since as being-other *than the Spirit,* it is already itself the life of the Spirit that can, by studying Nature, precisely know itself. Philosophy of nature is this knowledge of Nature through Spirit, understood as progressive recognition of Spirit in the being-other.

In the courses given by Hegel at the University of Jena in 1804 and 1805 (the manuscripts of which have been preserved), time is the first moment of the philosophy of Nature, the first form of the exteriorization of Spirit in nature. Time is defined by two concepts, the infinite and the negative. Negativity characterizes the destructive aspect of time, which he later described in detail in his 1817 work, the *Encyclopedia of the Philosophical Sciences.* As for infinity, it leaves open the possibility for a positive determination of time, which is likely to give itself to Spirit. From this double characterization of time flows the dialectic of the three temporal dimensions: present, future, and past. The first moment of time is the present, the Now. The Now manifests itself but does not last; it is immediately suppressed by the future, which comes to take its place. The Now has for its very being no longer being. Once suppressed, the Now becomes the past. The past, in turn, suppresses itself in the sense that it leaves a place for a new Now to come forth. In other words, the future is the negation of the Now, and the past is the negation of the future, and therefore the negation of the negation of the Now. Since double negation is affirmation, the past is the affirmation of a (new) Now. At this point, Hegel distinguishes two forms of time with the help of his logical theory of the two infinites. Either the new Now is a Now without a past, a pure Now without a relationship to the preceding Nows, or time is nothing other than the indefinite repetition of a Now always identical with itself, the bad infinity proper to Nature. In this unending linear movement, there is neither newness nor progress. As Hegel was to say later in Berlin, in nature there is nothing new under the sun. Or, the new Now is a Now of the past, a present that returns to the past, to include it in itself and to enrich itself even more. The image of the circle replaces that of the line. This "real" time is true infinity, which, in a circular movement, goes from the present to the present, through the future and the past. From this real time flows the principle of historicity: the living conservation of the past in the present.

In his 1805–1806 course on the philosophy of nature, Hegel explains the consequences of the primordial role of the past in the dialectic of real time. The past is not only one of the dimensions of time, it is the truth, the goal of time. According to Hegel, the privileged meaning of time is the past, understood not as a moment isolated from time, but as the culmination of "real" time, the concrete present. Against philosophers such as Schelling, who wanted to denigrate if not abolish time, Hegel affirms both the temporality of all Being, in that time is the supreme power imposing itself on all Being, and the rationality of this temporality, in the sense that the true knowledge of beings must consider the latter in light of their historicity. Philosophical knowledge is not the eternal contemplation of the eternal; it is knowledge of being "in its time," according to the temporality that is proper to it. Hegel reverses the traditional relationship of the subordination of time to eternity. The truth of time is not an absolute eternity, since, on the contrary, it is time itself, elevated to its real form, that is the truth of eternity.

Space, Time, and Negativity

The courses on the philosophy of Nature dating to Hegel's Berlin period (1818–1831), which provide commentary on the second part of Hegel's *Encyclopedia* appearing in 1817, do not call into question the philosophical rehabilitation of time undertaken in Jena. Hegel, however, leaves in the background the dialectic of time in order to concentrate on its negativity. According to Hegel, Nature is the Idea in the form of otherness and exteriority. The form of exteriority is divided into the two forms of space and time. The principal difference between space and time is negativity. Space does not allow negativity to deploy itself within it; negativity remains, as it were, paralyzed. The different parts of space coexist next to each other without cancelling each another out. It is not the same for time, the negativity of which incessantly relates to itself and continually suppresses its own moments. In fact, time is the being that, in being, is not, and in not being, is

(*Encyclopedia,* §258). In the *Science of Logic,* Hegel distinguishes pure indeterminate nothingness, which designates the nothingness that is not at all, from determinate nothingness, the non-Being that contains an essential relationship with Being. Negativity is the negation of negation, which ensures the conversion of determinate nothingness into Being. In the light of these logical determinations, it is clear that time is neither pure nothingness nor determinate nothingness, but a type of negativity. Time is the continual passage of Being into nothing—from the present into the past—and from nothing into Being—from the future into the present. It is this double passage that defines the negativity of time. Only the present is; it enjoys in nature an absolute right. But the present contains within it the negativity of time, such that it does not cease to suppress itself and to disappear. Time is a "going-out-of-itself" (*Außersichkommen*), the "negativity going out of itself" (*die außer sich kommende Negativität*). Time projects Being out of itself; it disperses it in a constellation of present, future, and past moments, all exterior to one another. For Hegel, the negativity of time is ecstatic, not so much in Martin Heidegger's sense, but in the *ekstatikon* of Aristotle, who, in his *Physics,* attributes to time the origin of the corruption that is inherent in all natural movement. In Nature, temporal negativity is essentially destructive, the result being pure, indeterminate nothingness, the irreversible disappearance into the past. Hegel uses a play on words in comparing time (Chronos) to the Greek god Kronos (Cronus) who engenders everything and devours his own children.

Becoming

Time not only involves the irreversible disappearance of events into the past. The moment of the disappearance supposes the continual birth of the moments that are destined to disappear. Time includes within itself a certain generation, which Hegel conceives through the category of Becoming. Time is, more exactly, the "intuitioned Becoming." According to its logical definition, Becoming is an alternation of birth and disappearance; it is formed by the unity of these two concepts. But logical Becoming and temporal Becoming could be confused, and the adjective *intuitioned* is there to distinguish them. Intuition traces the boundary between temporal Becoming and logical Becoming, as pure thought. Being, nothing, and Becoming are thoughts, but time is not of thought, and that is why it is intuitioned Becoming, which is experienced in existence. The concept of time is thought, and it is, like all concepts, eternal. Time itself in its existence is intuitioned. That time is a form of Becoming also means that it is not a fixed, permanent framework in which things happen. The only permanent thing in time is the absence of all permanence. Things are not in time, since time itself is in things in the form of an unceasing negativity that devours them from the inside. As Becoming, time is a river that carries everything away with it, including its own banks.

History and Spirit

Hegel clearly distinguishes the domains of Nature and of Spirit. In nature, the past is an indeterminate nothing; events disappear and for the most part leaving no trace. It is not the same for the domain of the Spirit, which is able to give a new opportunity to the past. Time is the "tomb" of the event, but the Spirit preserves the past. That's why history lives only in the Spirit. Most of the time, German idealist philosophers distinguished time from history, but without enquiring into the connection between these two concepts. The originality of Hegel's philosophy is that it allows one to understand the transformation of time in history. It is in the *Phenomenology of Spirit* that we find the clearest development of the transcending of time, that is, the passage of natural, linear time, the indefinite series of Nows, to historical time, which preserves the past within it. The possibility of the passage of time into history rests on the idea that time is the existing concept. This thesis means that time is not opposed to concept, to Spirit, since, on the contrary, it is the Spirit's mode of existence.

How does the passage from time to history take place? It is achieved principally through three operations of consciousness. Transcending the evanescent Now takes place in language, understood as speech and writing. Speech transforms the negativity of the Now into a stable and universal reality, and writing fixes this speech, still in flux, into a permanent sign. Consciousness also preserves the

Now through the work of the interiorization of memory (*Erinnerung*). Interiorization is conceived by Hegel according to the Christological model of the Resurrection. It is what allows the Absolute Spirit to make the present be relived in the past, saving it from oblivion. Through memory, the Spirit converts the indeterminate nothing of the past into a new present, which is the foundation of history. In the ultimate movement of "Absolute Knowledge," Hegel develops a third form of the transcending of time, that of conceptual thought, which overcomes the negativity of natural time in order to extract from it immanent rationality. It is necessary to make an essential distinction between "effective history," which corresponds to the temporal course of events, and "conceived history," which is the retrospective understanding of events in thought by philosophy. The task of conceived history is to organize the chaos of events, giving them the form of the concept, to manifest the movement of the Spirit, which progresses secretly, like a mole, through events.

Hegel affirms that Spirit is time. This identity of time and Spirit is dialectic. On the one hand, Spirit is opposed to the bad infinity of natural time; on the other hand, it transcends the latter in order to unite itself with time in the movement of history. This identity ultimately has the meaning of "*Aufhebung,*" of a transcending by which the Spirit makes itself master of time, by means of language, the interiorization of memory, and conceptual thought. The finite beings that inhabit Nature—inorganic things, plants, and animals—are incapable of transcending the negativity of time that they contain in them, which henceforth manifests itself as a hostile power, a source of destruction and death. For finite beings, time will never be anything other than the destructive negativity of nature—a destiny. On the other hand, human beings possess within themselves the absolute negativity of the concept, which designates thought, and more generally, freedom. The concept is the power of time, in the sense that Spirit transcends its negativity, on the one hand, in the very knowledge of time, and on the other hand, by its capacity to transform natural time into historical time. The distinction, first presented in the *Phenomenology of Spirit,* between effective history and conceived history is made more explicit in the *Philosophy of History,* the aim of which is to decipher and translate, in the language of the concept, the palimpsest of represented history, the *historia rerum gestarum,* in which events and their memories are recorded through writing. The Hegelian conception of time also leads, in its final outcome, to thought of the history and of historicity.

Conclusion

When all is said and done, the Hegelian philosophy of Nature brings at least five original answers to the question of time:

1. *The desubjectivation of time.* Time as such is not an interior form of our consciousness, an "internal sense," but a universal determination of Nature present in all its domains.
2. *The mobility of time.* Time is not a fixed and permanent form in which events take place, but the very Becoming of things. From this point of view, things are not in time; it is time itself that is in all things in the form of their intrinsic negativity.
3. *The negativity of time.* Time is the destructive negativity of Nature; it plunges each being into the non-Being of the past. This concept of negativity allows us to take into account several aspects of time, such as the fleetingness of the instant and the irreversibility of the past.
4. *The dialectic of time.* The negativity of time unfolds according to a dialectic of three moments, from which flow two figures of time: on the one hand the indefinite and repetitive time of Nature, and on the other hand, the progressive and historical time of Spirit.
5. *The logicity of time.* The purpose of the desubjectivation of time is to establish the relationship of Spirit and time on a new basis. Time is not, in fact, a power foreign to Spirit, a destiny, but it can be transcended by Spirit in the sense that it can be spoken of, recollected, interiorized, and thought by Spirit. For this reason, the reflection on time begun in the philosophy of Nature is fully realized only in the philosophy of Spirit.

Hegel and Kant

Like Immanuel Kant, who sees time as the formal a priori condition of all phenomena in general, G. W. F. Hegel considers time as an absolutely universal determination of nature, which gives it a certain primacy over space. The *Encyclopedia* of Hegel seems to adopt the same presentation as Kant in his *Transcendental Aesthetic:* Time follows space, and the analysis of each of these two moments culminates in an examination of the corresponding sciences. Hegel refers to Kant several times, affirming that time is, like space, a pure form of sensibility or intuition. But behind these apparent affinities hides a systematic critique of the Kantian theory of time developed in the *Critique of Pure Reason.*

In the *Transcendental Aesthetic,* the objective of the metaphysical exposition of time is to analyze its a priori conditions, that which is necessary and universal. And yet, while taking up the main conclusion of this exposition, the very definition of time as a pure form of sensible intuition, Hegel gives it a resolutely different meaning. First of all, he sets out to show the dialectical relationship between space and time, whereas Kant merely juxtaposes them as two forms of our finite human intuition. But above all, Hegel interprets the pure intuition of space and time not through the subject, but through Nature. He thinks that one ought not to make space and time purely subjective forms of human nature, for time is not a condition of becoming; rather, it is becoming itself intuited, the destructive negativity inherent in Nature.

Certainly, Hegel grants Kant the claim that time, like space, is not something real, and is not, as Leibniz thought, an order of things. But the ideality of time does not make it one of the forms of our sensibility. Hegel expresses this Kantian concept in terms of his own thought and replaces the transcendental ideality of time with another form of ideality, designating its negativity, its power to dissolve all reality into the nothingness of the past. According to Hegel, it is therefore useless to want to classify time among subjective or objective beings. As the universal negativity inherent in nature, time might be described as "objective," but as the existence of the Idea in the mode of Being out-of-itself, it is brought back to the mind, and is, in this sense, also "subjective."

In Kant's writing, the purpose of the transcendental exposition is to show the determinations of a concept that constitutes the principles capable of explaining a priori the possibility of certain sciences. Actually, it is rather in the *Analysis of Principles* that this essential aspect of time is described in detail by Kant, who affirms at the beginning of the *Analogies of Experience* that the three modes of time are permanence, succession, and simultaneity. Permanence is the schema of substance by virtue of which I know a priori that substance persists through all changes of phenomena. This permanence is the condition of two other temporal relations: *succession,* which is the schema of causality, and *simultaneity,* which corresponds to the schema of reciprocal action. And yet, based on his understanding of temporality as destructive negativity, Hegel refutes one by one these three fundamental attributes of Kantian time. Simultaneity is thus completely foreign to time, since the latter is defined by its exact opposite, impossible coexistence. The opposite predicate, succession, does not offer an adequate grasp of time, for it masks its specific negativity more than it highlights it. The concept of succession is defective because it represents time as a series of isolated instants split between two domains: the present Now, which is, and the non-present Nows, which are no longer or which are not yet. Being and non-Being are maintained separately by representation, whereas, in truth, the negativity of time that flows from the Now implies an indissoluble unity of Being and nothingness at the heart of each

Now. From this point of view, the future and the past do not constitute other forms of Now but the presence of a negation in Being itself of each Now. By virtue of this negativity, time prohibits all a priori permanence in itself. Of course, certain beings last, but their duration is always of a relative permanence, a deferred death, even for things that we say defy time; for in time nothing persists, nothing remains. According to Hegel, the absolute nonpermanence of temporal things is due to the nonpermanence of time itself, which is ceaselessly transcending itself. Consequently, one should abandon the representation according to which time is a permanent receptacle in which things take place. Kant believes that things change in time, which is, in itself, immutable and fixed. But this, for Hegel, is failing to grasp the very negativity of time. The understanding of time as negativity and becoming therefore implies, in fact, a radical critique of the Kantian theory of time. Time is not that in which things take place, but their very becoming, their own disappearance, as is stated in §258 of the *Encyclopedia*.

In both the transcendental and metaphysical parts, the Kantian exposition of time in the *Transcendental Aesthetic* is therefore criticized by Hegel. Why? Precisely because the transcendental problematic impedes a real understanding of time as negativity, which is at the heart of Hegel's philosophy. The ambiguity of the Kantian conception of time is that it tries to reveal the conditions of the possibility of experience in general and, at the same time, Newtonian physics in particular. This explains why the Kantian understanding of time is predetermined by categories coming from physics, such as causality, substance, and reciprocal action. For Hegel, time is not principally determined by the categories that make possible the physical science of nature, but by its proper dialectical structure, deployed in the present, the future, and the past. Time is the continual, reciprocal passage of Being into nothing—from the present into the past—and from non-Being into Being—from the future into the present.

Heidegger, Martin (1889–1976)

Among philosophers of time, Martin Heidegger is one of the most famous. He describes humans as essentially temporal—that is, as "beings in time." Bringing together philosophical currents including phenomenology, philosophy of life, hermeneutics, and ontology, he developed a new philosophy he called Existentialism. His interpretation of the history of philosophy is critical for understanding his works.

Life and Works

Born on September 26, 1889, in Messkirch, in southwestern Germany, Heidegger intended to become a Roman Catholic priest, but after 2 years of theological studies at Freiburg University he switched to mathematics and natural sciences, finally taking a doctorate in philosophy (1913). After completing his postdoctoral thesis, *Die Kategorien und Bedeutungslehre des Duns Scotus* (Doctrine of Categories and Theory of Meaning in Duns Scotus), Heidegger broke with classical Catholic philosophy in 1919 and became an assistant to Edmund Husserl, the founder of phenomenology. In 1923 he was appointed professor at Marburg University and in 1927 Heidegger published *Sein und Zeit* (Being and Time), regarded as one of the most important and at the same time most controversial books in philosophy. He returned to Freiburg one year later as Husserl's successor, where, in 1929, he published three influential books: *Vom Wesen des Grundes* (On the Essence of Ground), *Kant und das Problem der Metaphysik* (Kant and the Problem of Metaphysics), and *Was ist Metaphysik* (What is Metaphysics).

Heidegger's most controversial years were from 1933 to 1945. As a conservative and staunch anti-Communist, he supported some aspects of Hitler's policies and was elected rector of Freiburg University on April 29, 1933. He joined the party shortly afterward—less out of conviction and more to strengthen his position, and although he never embraced Hitler's anti-Semitism, he remained vague about his relationship with the Nazis even after the war. More positively, as rector he prohibited anti-Jewish posters in the university and protected the Jewish professors Hevesy and Thannhauser. He shared a close personal friendship with the Jewish philosopher and political theorist Hannah Arendt in 1925 and again after 1950. His major work *Being and Time* is dedicated to Edmund Husserl, his Jewish predecessor at the University of Freiburg. Heidegger's tenure as rector lasted less than a year, as he was forced to resign after refusing to remove two deans in disfavor with the Nazis. While he never renounced the party, his distance from it was clear in 1944 when he was declared expendable from the university and sent to dig trenches along the Rhine. The relatively few publications from this period include his important essays on Plato's concept of truth (1942–1943). Heidegger's "philosophical turn," which may have begun during the 1930s, seems more evident after the war in his books on Nietzsche and the English publication in 1950 of *Off the Beaten Track* (*Holzwege*). The nature of this turn is contested among scholars, but the theme of philosophical inquiry as a continuous path of understanding is especially appropriate for Heidegger—one that he used repeatedly to describe his own work. He died in 1976 and was buried in Messkirch.

Philosophy of Being and Time

The title of Heidegger's renowned work *Sein und Zeit* (Being and Time) describes the book's key insight about the essential temporality of human existence. In the book, he reveals a remarkably original philosophy that required a whole new vocabulary in order to transcend inadequate understandings of human existence. His lifelong philosophical project attempted to correct a perceived deficiency of Western philosophies from Plato (427–347 BCE) until the rationalistic and scientific worldviews of the 20th century. Many of those philosophies provide great insight into the human condition, especially the classic works of Plato and Aristotle, but according to Heidegger they went astray by inadequately explaining human existence as the precondition for all understanding.

Various English translations preserve his technical terms by keeping them in the original German or by capitalizing them, and often by using hyphens to string together words that together form a unique idea. "Sein" or "Being" is the indefinable concept that begins to convey insight into the human condition when it has been considered carefully—with "Sorge" or philosophically reflective "Care." "Zeit" or "Time" is paired with Being because humans experience reality only within a temporal framework. We experience reality not as a series of present moments, but rather as creatures with memory of the past, awareness of the present, and expectations for the future. Humans come to know Being temporally, in Time, and achieve self-understanding within specific historical circumstances. This insight is conveyed by the term "Dasein" or "There-Being"; illumination, or "Disclosure" of Being's meaning is achieved with reflection upon how humans think about existence in our necessarily limited and temporal way. Humans are thus "beings in the world" and "beings in time."

According to Heidegger, the Being of the human being is fundamentally temporal. This position is the result of an existential analysis of the human being as mortal—Being in relation to death ("Sein zum Tode"). Heidegger's existential analysis of humans' fundamentally temporal nature includes a reflection on this relation to death. Death is the end of each individual's human possibilities ("Sein zum Tode"). Human beings know about their death and are thus able to anticipate the end of their possibilities as their end. Human beings as Beings-in-the-world and Beings-in-time realize that no one else will die their deaths. So the anticipation of death "invites" human beings to live their lives with awareness. If human beings do not take this invitation seriously, they fail to be what they should be. They fail their true nature.

Just as humans do not choose whether to come into existence, the circumstances of particular human lives are also very much given. Heidegger describes this with the term *Geworfenheit* or "Thrown-ness." This means that individuals as Dasein comes to know that they are in Time without having been their own cause.

> Only an entity which, in its Being, is essentially Futural [oriented to the future] so that it is free for its death and can let itself be thrown back upon its Factical "there" by shattering itself against death—that is to say, only an entity which, as Futural, is equiprimordially in the process of having-been, can, by handing down to itself the possibility it has inherited, take over its own Thrown-ness and be in the moment of vision for "its Time." Only authentic temporality which is at the same time finite, makes possible something like Fate—that is to say, authentic historicality. (*Sein und Zeit,* p. 385, translation by Macquarrie & Robinson)

The person as Dasein is thus substantially structured by temporal relationships—in relationship with the past as memory and history, with the future as anticipations that include the inevitability of death, and with the present as a reality shaped by both past and future. The focus on death and mortal limitations is not meant to be morbid, but rather to deepen the understanding and appreciation of human life. Life appears to be diminished in approaching death, but this process reflects the essence of the human being as a presence becoming absence. Awareness of Dasein limitations such as impending death drives home this reality. On the one hand it is frightening, because death implies the end of all potentialities for the person. But on the other hand, the deep awareness of death's ultimate finality brings with it a call to consciousness. Consciousness is not a moral motivation, it is the deep awareness that makes personal freedom possible. This dynamic gets at Heidegger's idea that "Non-Being" makes Dasein ("There-Being") possible. In terms of Time, the reflection of nothingness transforms time and fills us with a wonder for every moment.

Heidegger's Later Philosophy as Philosophy in Time

By the 1930s Heidegger had already begun to revise his ideas in *Sein und Zeit*. The problem is that his philosophical analysis of Time presented it as an eternal and transcendent truth, even as he was attempting to establish the essentially temporal structure of humans as Dasein. This motivated him to struggle with these themes in the philosophical systems of Schelling and Hegel, as well as with the poetry of Friedrich Hölderlin. His goal was to uncover a thoroughly temporal phenomenology, but he was not satisfied with the historical aspects of his thinking and wanted to uncover a more fundamental understanding of the temporal structure of human "Dasein." He used two words that sound similar in German to emphasize the importance of history and time: *Geschichte* means history and *Geschick* means destiny, future, fortune, but also skill. While it is historical, his philosophy is at the same time a skill that makes it possible for the person to accept the future.

Heidegger's investigations into the history of philosophy focused on the question of understanding itself and on the way historical circumstances shape the whole structure of thought. The image he used to describe this situation was a horizon that is formed by the meeting of the land and the sky, that is, between what is given and what is absent. The absence is as important as the existence, or "Dasein," in philosophy as well. Metaphysics is the philosophical enquiry into the nature of Being that began with Plato. From that time until Hegel, philosophers continued to contemplate the nature of Being as divine. The reversal of this connection that came with Nietzsche had great consequences. The natural sciences and technology progressed with great achievements during this time, but they did so according to greatly mistaken assumptions about the nature of existence.

This can be perhaps best shown with an example. Uranium fission creates an object that, in itself, remains insignificant. Only after its possible uses have been considered, such as the creation of energy, can it be meaningfully understood as fuel for "nuclear energy." Nuclear energy, with its both peaceful and wartime uses, serves as a good example because it demonstrates how human understanding is never neutral. A purely technical and practical understanding of objects is an illusion—and an illusion made possible by the modern scientific mindset that had radically alienated careful attention to Dasein. Even while presuming to be neutral in terms of metaphysics and value, it actually assumed an anti-historical metaphysical standpoint. It presented Being as the eternal present—a never-ending "now." Within this worldview, existence is classified according to a functional rationality of technical production. This idea, which Heidegger describes with the term "Ge-stell," explains how such a dangerous technology such as nuclear bombs could be developed by scientists claiming to be neutral. Even so, the chance for a "turn" is possible with new ways of thinking. According to Heidegger later in his career, a new understanding of human existence could reveal itself that is aware of both existential absence and presence, as well as both the holy and the divine.

This later view was an even more radical conception of existence. Being can be grasped intellectually only when it is aware of what is absent. This reality is demonstrated by serious reflection on human history. Yet, as Heidegger reached the end of his career, he became more skeptical about whether humans would "turn" from their objectification of reality.

Heidegger's Significance and Influences

Heidegger has been generally recognized as the most important philosopher to carefully investigate the nature of time and of being. He reached beyond the usual philosophical history from Plato to Nietzsche where the question of human existence had always been assumed as a given. As such, the understanding of existence itself remained shrouded, especially the peculiarly temporal nature of being that is known by its absence. His philosophy is a phenomenology because it considers how Being is revealed in human experience—often in explicit ways, but also in implicit and overlooked ways. Heidegger's is also an existential philosophy, because it considers the structure of all existence from the particular perspective of human existence. He uncovers the nature of human existence as situated in place and time, but also in how humans are capable of contemplating, discovering, and shaping existence. His philosophy is a metaphysics because it is an understanding of existence developed from what is—in other words, from Being itself—and not from a natural science point of view. His philosophy is a hermeneutics (way of interpretation) because it starts from the position that we come to greater understanding of Being by being made aware of our prejudices, and never by observing Being from a supposedly objective perspective. At the same time, by becoming ever more aware of our own prejudices, we can subject them to examination.

Much of Heidegger's philosophy remains in dispute. Analytical philosophers have ridiculed Heidegger's play with language, and linguists have shattered his etymologies. Yet, French existentialists like Albert Camus and Jean-Paul Sartre embraced it and used it to influence a whole generation of educated Europeans and Americans. The autonomous subject was understood to be capable of constructing its own personal existence—an existence potentially independent of reasonable coherence. Hermeneutic philosophers such as Gadamer have further developed many of Heidegger's ideas, especially the notion that preunderstanding (or prejudices understood in a neutral sense) structures more conscious understanding. Heidegger has also profoundly influenced theologians such as Rudolf Bultmann and Karl Rahner. Bultmann developed an existential biblical theology based upon the conviction that the Bible's meaning must be intelligible for modern people and relevant to their existing concerns. Rahner was a former student of Heidegger's who developed a new existential theology that reflects on death, the meaning of freedom, and the nature of God. Without straying from traditional Roman Catholic teaching, Rahner benefited from Heidegger's understanding of God as absolute mystery that, Rahner believed, is revealed as love in Jesus Christ.

Heidegger also influenced ethical thought, especially with his critique of the modern technological way of thinking that has forgotten about Being. Technological progress warrants suspicion because it professes no values and thus its progress is judged according to implicit and hidden principles. The apparent technological successes of the modern period convinced people of its power, and yet blinded people to the dangers that its worldview represented. As environmental and political disasters have demonstrated, technological resources can be used in dangerous ways when guided by wrongheaded principles. Even Heidegger himself was forgetful of this point during the period of his support for the Nazis. Still, Heidegger's philosophical insight remains important, that our understanding of Being requires that we appreciate its relation to Time—to its past, its future; and that this appreciation will continually shape our present.

Heraclitus (c. 530–475 BCE)

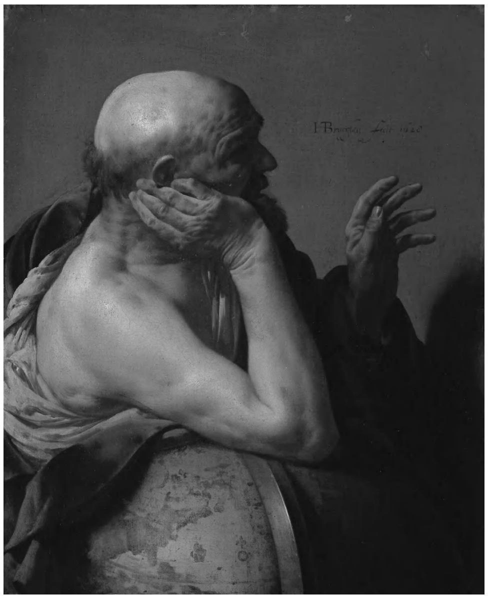
Heraclitus is considered among the greatest of the Presocratic philosophers. Flux and time play particularly important roles in his thinking. Even though the fragments of his book *On Nature* had an enormous impact upon such diverse philosophers as Plato, G. W. F. Hegel, Friedrich Nietzsche, and Martin Heidegger, not much is known concerning the particulars of his life. However, we do know that he was born in Ephesus, came from an old aristocratic family, and looked unfavorably upon the masses. According to Apollodrus, he was about 40 years old in the 69th Olympiad (504–501 BCE).

Relativity of Time

The most influential aspect of Heraclitus' thinking about time is the concept of the Great Year or the eternal recurrence of everything, an idea that was taken up later by Zeno of Citium (the founder of the Stoa) and Nietzsche. However, within his philosophy, Heraclitus also clarifies other aspects of time. He was clearly aware of the relativity of time. When he explains that the sun is needed for the alteration between night and day to occur, it becomes clear that he was conscious that daytime and nighttime are dependent upon certain conditions. A certain time exists only within a specific framework or paradigm. If the framework changes, then the concept of time within it changes, too. We would not have daytime within a world without the sun. Time is dependent upon a specific perspective, and many distinctions concerning time cannot be drawn from only a cosmic or universal perspective.

Unity of Opposites

Heraclitus criticized Hesiod for not having the best knowledge concerning daytime and nighttime. Only the masses regard Hesiod as a wise man, but truly he was not. According to Heraclitus, daytime and nighttime are one, which Hesiod had failed to realize. From a global perspective, one cannot distinguish



Heraclitus, *painting by Hendrick ter Brugghen. Heraclitus was a Greek philosopher who proposed that everything is in a state of flux and that fire is the principal element of matter.*

daytime and nighttime. One has to be a participating spectator in order to employ the distinction meaningfully. Even though the distinction in question works well from a pragmatic perspective, this does not imply that it is correct. From a universal perspective, the distinction between day and night is not supposed to make any sense, as God is supposed to represent the unity of opposites; that is, God is supposed to be the unity of day and night, as well as summer and winter.

Time as Metaphor

Even though opposites do not exist, Heraclitus himself employs opposites. Concerning time, he clearly holds that there are people who are connected to the night and others who are linked to the day, and he attributes different values to these two types of paradigms. According to him, only the night-roamers are the initiated ones. They have wisdom and they do not belong to the masses. The masses are uninitiated and are connected to the day. Even though, from a global perspective, night and day are one, nighttime and daytime stand for something different. Here, they represent people who are either initiated or uninitiated into wisdom.

Time and Order

Only the initiated know what time really is. Time is a type of orderly motion with limits and periods. Heraclitus also specifies in more detail what he understands as order concerning time, and he explains that it is important that the same order exists on various levels. However, time cannot be reduced to only one aspect of order, as Heraclitus also identifies time with a playing child; that is, time is the kingdom of a playing child. Even though the aspect of order is necessary for games, there is more to the process of playing a game, as there are also the aspects of playfulness, freedom, and chaos. To stress also the important disorderly element represented by time, Heraclitus attributes to this concept his idea of the unity of opposites. Wherever there is order, there has to be chaos. However, that chaos is relevant might only mean that even though there is one certain order in the universe, we cannot securely predict the future. Even though everything is necessary, from our perspective anything can happen, as it is impossible for us to foresee the future.

Time Is Cyclical

According to Heraclitus, the order of time is the cycle. Periods and cycles appear at various levels of existence. There is the world cycle or Great Year, but there is also a human cycle, the cycle of procreation. Human beings are born, grow up, and give birth to other human beings so that the cycle of human life can start again, which happens approximately every 30 years. In this way, a man becomes a father and then a grandfather. However, the most important idea in the philosophical reception of his thought is Heraclitus' world cycle, referred to as the Great Year, or the eternal recurrence of everything. Analogous to human lives, there is a period or a cycle in the progression of world history. The world is supposed to be an ever-living fire that is kindled and extinguished in regular cycles. One cycle represents a Great Year, which has the (surely metaphorical) duration of 10,800 human years. By presenting the Great Year in his philosophy of time, Heraclitus also reveals an option for an immanent type of immortality. The concept of the Great Year is of relevance on various levels. It may be analyzed from a metaphysical, natural philosophical, scientific, ethical, and religious perspective.

Herder, Johann Gottfried von (1744–1803)

Born in Mohrungen, Prussia, Johann Gottfried von Herder attended the lectures of Immanuel Kant in Königsberg for 2 years, beginning at 18 years of age. Herder was most fascinated with Kant's early scientific reasoning, especially his philosophy of nature.

At the age of 21, Herder became a Protestant pastor. In Königsberg, Herder became friends with the counter-Enlightenment figure Johann Georg Hamann. Both Herder and Hamann rejected the later Kantian critical philosophy, and had already rejected any notion of a "faculty." Both had little interest in "time" as an abstraction. Instead, all consciousness should be thought of as language-based. Though his friend Hamann was averse to the entire tradition of rationalism, and though he himself never accepted Kant's critical philosophy, Herder was a rationalist and an idealist when history was the subject.

Herder traveled throughout the German-speaking lands and conversed with many of the greatest minds of his time. He was interested in all things natural, human, and divine. On December 18, 1803, Herder passed away in Weimar.

The German Historical Sense and Herder

Johann Gottfried Herder occupies a permanent, important place in the history of human thought concerning time, for it was he (with his contemporary Hamann) who introduced a "historical sense" to the German nation as a whole. Of course, before Herder there were authors with a strong historical sense. But all these influences and predecessors were non-Germans, especially the figures from the French Enlightenment. And, of course, before the Enlightenment, the Scholastics had understood time and history in the abstract. But they were more interested in "eternity" than in human history. They distinguished *sacred* from *secular* time in order to give absolute priority to the former. The Scholastics lacked a sense centered on natural and human history. Herder provided a new mode of thinking for the German public by offering just such a historical sense.

Most important, this historical sense was lacking in the orientations of Leibniz and Kant. The thought of Leibniz was almost entirely nonhistorical. Mathematics and physics (monadology) do not require a developed notion of human history, because they are largely theoretical, abstract sciences. Perhaps Kant sought to sidestep the question of history (and phenomenology) by focusing largely on the transcendental structures of the ego. His thinking was strikingly nonhistorical, even transtemporal. The reader of Kant is often left with a sense of timelessness and of rationality at rest, a sense of the structure, but not the content, of time.

Herder and Hamann

Herder had a noteworthy German cohort in developing a historical sense, Johann Georg Hamann. Herder's senior and friend, Hamann had also embraced history and sought to instill the German nation with it. Hamann's thought was largely a reaction to the Enlightenment and to the ideas of Benedict Spinoza. The German public, in general, had reacted to the twin specters of Spinoza and Enlightenment science with fear and loathing. Spinoza's ideas were considered deterministic and covertly antireligious. The advance of English science, especially chemistry, was threatening because the "soul" could then perhaps be explained by the chemical processes of the mind within the brain.

Hamann sought to guarantee religion a safe respite. Faced with the advance of Spinoza's ideas, Hamann retreated into irrationalism and a sort of counter-Enlightenment orientation. He sought to link biblical history with modern history, and to prevent any juncture between history and science, materialism, or atheism. Again, Hamann had a sense of history, but it was of a religiously orthodox orientation; history is the story of the divine will. Above all, he viewed *history as entirely sacred;* a strictly secular history could not be conceived of. In short, Hamann viewed history as an irrational but divine phenomenon.

Confronted by the twin specters of Spinoza and Enlightenment, Herder chose a different strategy from Hamann. While Herder still viewed history as a divine phenomenon, he claimed that history is *rational and an object of science.* As the third element of his strategy, Herder chose to incorporate a broad range of natural sciences into his scientific account of history.

Like Hamann, Herder saw history as divine, but in a very different sense. Hamann had sought to develop history out of revealed scripture; Herder, on the other hand, attempted to delete all religious or mythological content from his history. He would accept no divine intervention, no miracles, as a cause in history. In short, Herder's explicit project was to develop a *scientific (nontheological) account of history.* He saw the inevitability of considering time not as entirely sacred but also as secular (natural scientific), and even as an agency of human free will (the historical sense). And so he set off on the project of authoring a coherent history of the universe, nature, man, society, and God, all strictly within a natural scientific methodology.

Herder was not concerned with Spinoza, since his natural science was strongly influenced by Roger Joseph Boscovich, in that his theory of atoms was a point-particle theory rather than the Newtonian corpuscular theory—meaning that instead of Newton's extended atoms, Herder insisted on Boscovich's dimensionless force-points. (Recall that Herder, like Kant, was in the generation of thinkers immediately after Newton, Leibniz, and Boscovich. It seems most likely that Herder discovered Boscovich's ideas when Kant was struggling with them in the early days at Königsberg. Kant finally resolved his struggle with Boscovich by incorporating the theory of force-points into his own natural philosophy in his late work *Metaphysics of Natural Sciences.*) Force-points completely subverted Spinoza's monism and determinism so abhorred by the German sense of piety. Boscovich's natural science (*Theory of Natural Science,* 1776) was a theory of *force,* not *substance.* By adopting an atomism most closely related to Kant and Boscovich, Herder was able to sidestep Spinoza's "deterministic" metaphysics entirely. But Herder could not deny the advance of Enlightenment science, so he chose to concentrate on the natural within history. He began with an explanation of the universe and the origins of nature, and then worked his way through the rise of animal life. Finally, he gave a historical account of human civilizations.

Herder saw that the sciences had to be given a sense of time. Previously the sciences were taught as a hierarchy rather than as having a shared history. The static classifications of Aristotle and Linnaeus could no longer do justice to the advance of science. To account adequately for the development of the universe, Earth, and man, a timeline was necessary with which to distinguish developmental stages. This meant discovering the unidirectionality of time and of a sequence of events following that linear model. The sciences could no longer burst forth fully grown from the brow of Zeus.

Developing an interdisciplinary history of the sciences was a daunting challenge for Herder. Writing well before Charles Darwin, Herder did not have a theory of evolution. Nor did Herder have the advantage of the theory of developmental history authored by Karl Ernst Ritter von Baer. Yet he traced history from the origins of the universe to the rise of humankind across a panorama of the sciences. Breaking completely with Hamann, Herder saw in history not the divine will of God, but instead the actualization of divinity in man.

Herder's Legacy

Herder's contributions to the historical sense—religion, rationality, and science—proved fateful to subsequent German thought on history. After Herder, the first on the scene, Johann Gottlieb Fichte, adopted the religious interpretation of history provided by Herder; history was indeed the actualization of the "absolute ego" in man. Fichte also adopted the notion that there is a deeper logic and rationality to history; it is the gradual actualization of the Idea (logos). Fichte returned to Hamann's tradition of pietism and developed his system of ethical idealism entirely within a quite preachy, harshly moralistic tone. But Fichte ignored the natural sciences in favor of his own principle of ego. Next in the line of succession came F. W. J. Schelling. In keeping with these predecessors, Schelling viewed history as sacred time. He also saw history as the gradual unfolding of an Idea, and so all things are ultimately knowable by reason. In contrast to Fichte, Schelling greatly esteemed the natural sciences. If Fichte's system may be called "ethical idealism," Schelling's system could be called an "idealism of nature" or "objective idealism." Thus Schelling was a more complete replication of Herder's historical sense even if in the strange new idiom of systematic idealism. After Schelling, Hegel advanced the historical sense to perhaps its most extreme form. In fact, Hegel adopted Herder's three contributions, mediated through Fichte and Schelling, as his own. Religion had its eternal safe haven in Hegel's Absolute Spirit, and history was the moving image of eternity. Also, history had its own rational process for Hegel, which may be captured in a system of logic. Rationality is indeed only the standard of knowledge for a historical stage of development. Hegel's Absolute sought to subsume Nature and man entirely within itself. Finally, Karl Marx reworked Hegel's absolute idealism, mediated by Ludwig Feuerbach, the utopian socialists, and later Darwin, into an all-inclusive theory of historical materialism. Directly or indirectly, these thinkers traced several fundamental elements of their historical sense back to Herder.

It should be observed that each stage within Herder's history was equal to every other; there is no progress or higher spirituality as history proceeds (in contrast to Hegel's notion). He did believe, though, that human history should be narrated ultimately in terms of races and nations. Thus Herder truly set the scene for Fichte's entrance onto the stage.

Herodotus (c. 484–c. 420 BCE)

Herodotus of Halicarnassus in Caria (currently Bodrum on the Aegean coast of Turkey) was one of the earliest known historians and is most renowned for his chronicling of the Greco-Persian Wars. His approach to the writing of history set a precedent for later historians' concern with establishing causal links between past and current events.

At the time of Herodotus' birth, Halicarnassus was a Greek city located on the fringes of the Persian Empire and thus subject to their monarchal control. Herodotus examined the root of the great conflicts between the Greeks and non-Greeks; from its origins in the Lydian kingdom, to the failed revenge of the Persian King Darius at Marathon, to the final unsuccessful efforts of his son King Xerxes at the Battle of Thermopylae and the famous naval battle at the Straits of Salamis off the coast of Attica. Very little is known of the author's life except that he never claims to be an eyewitness to the events he describes, although he often makes mention of conversations with those who were present, as if he were there. It is thought that many of these conversations might have come secondhand via the exiled grandson of the Persian Zopyrus.

Herodotus' *Histories* is composed of nine books starting in Book 1 with the story of the Lydian king Croesus in the mid-6th century BCE and ending with the founding of the Athenian empire following the second Persian War in approximately 480 BCE. The books of Herodotus' *Histories* cover a significant period of time in which the author attempts to uncover how the enmity between Greeks and Persians began. In doing so, Herodotus' main narrative is composed of many smaller narratives in great detail. These narratives focus on a set of chronological events surrounding the reason for the conflict between Greeks and non-Greeks. Often these narratives temporarily move backwards or sideways to describe circumstances or details that Herodotus feels shed light upon the main thrust of the story. Herodotus' historical method not only is one of enquiry into his narrative but also integrates a line of questioning of his sources, not all of which he trusted. Often he writes that while he is under a moral obligation to report what was said to him, he is under no obligation to believe it, and this inability to decide is cited. While Herodotus never disguises the fact that the Greek-speaking world is the geographic and cultural center of his perceptions, he is often very open-minded when describing the cultural details of foreign societies, although he inevitably must compare them to his own, by relating what he views as a rationale for diverging modes of life and religion.

For Herodotus and his historical reasoning, actions are the result of a prior cause or reciprocity. A wrong inflicted in the past will be returned in equal measure in the future; this is especially the case in regard to kinship relations. And this is why Herodotus' work extends to the distant past to find the answer to the events that caused Greeks and non-Greeks to go to war. In addition, the historian does not focus his energies upon the logical explanation of events and human actions, as they often seem random or too easily assigned to fate or the intervention of divine will, and to some readers this will lend to a sense of storytelling. Although some accounts by Herodotus have been charged with straining the reader's credulity, one should not discount all he records. It is believed that Herodotus died sometime in the 420s while living in the Athenian colony at Thurii in Southern Italy.

Hesiod (c. 700 BCE)

Hesiod was a probable contemporary of Homer, and the writings of both represent one of the earliest phases of Greek literature. Although a variety of writings are attributed to him (his only known complete works are *Theogony* and *Works and Days*), Hesiod stands out not only as an important source of Greek mythology but also as one of the first Western philosophers to conceive of and elaborate a cyclical view of time. He is said to have been a simple shepherd who was rewarded with deep insight by the Muses, who came to him in a mist. His views reflect a more practical understanding of life than do those of many of the ancient Greek philosophers who were from an elite class.

Theogony, which likely includes a compilation of oral traditions and myths, tells of the origins and chronology of the gods as well as the creation of the heavens and the earth. Like nearly all creation myths, it sets up a view of time and a relationship between humans and the world of the gods. However, it is in his *Works and Days* that Hesiod elaborates his views on the topic of time.

Hesiod divides existence into five stages, or "Ages of Man." The first, the Golden Age, is ruled by Cronus, the god of time. Under his control, it is an era of truth, justice, and peace. People are filled with wisdom, are of a contented nature, and, though considered mortal, are ageless. Zeus, the son of Cronus, takes over at the dawn of the Silver Age. It is one in which differences and discord begin, and morality declines. Human existence is shortened and the necessity to work is born. During the Bronze Age, strife and violence continue to increase, as do human passion and frailty. The fourth stage is the Heroic Age and is connected with the Trojan War. While human attributes seem to improve somewhat, violence dominates. The last is the Iron Age and is associated with the present. In many ways, it is similar to the present age of degradation as conceptualized in Hindu (Kali

Yuga) and Buddhist mythology. Human life is at its shortest, while truth, justice, and peace are suppressed by crime, greed, deceit, and violence. The gods forsake humanity and evil rules.

Ultimately, however, Hesiod uses *Works and Days* to provide a vindication for morality and the righteous. In an eschatological vision, goodness and justice (*dike*) prevail and triumph, while injustice (*hubris*) loses out. A subsequent section of the text is devoted to teachings on morality and ritual propriety.

Hesiod's influence can been seen in the Pythagorian concept of a cyclical reality and possibly in the works of Homer as well. His elaboration of a golden age, his views on the necessity and value of physical work, and his prescriptions on morality have all had a continuing impact on Western thinking.

Hibernation

The term *hibernation* comes from the Latin word *hibernare,* which means to pass the winter. The term is commonly used for a type of deep winter dormancy in some animals (i.e., mammals, birds, reptiles, and amphibians). A similar type of dormancy that occurs in summer is referred to as estivation. Some insects and snails also exhibit a similar state of dormancy in winter that is often called winter estivation or diapause.

Hibernation (winter dormancy) involves a periodic (seasonal) drastic reduction of the animal's metabolic rate and body temperature for an extended period of time. Generally, in hibernation, the body temperature drops almost to that of the surroundings (the bear being a well-known exception). Basic body processes, like breathing and the rate at which the heart beats, are drastically reduced so that the hibernator appears almost to be in a comatose state. The hibernating animal then lives through the winter on a reserve of body fat and/or externally stored food until it awakens in the spring.

Hibernation is therefore considered to be a fundamental adaptation to the environment since it is essentially an adjustment in the animal to allow its survival during those periods of the year when environmental conditions are so severe that exposure to the elements will be fatal. To survive in these harsh conditions, some animals can temporarily migrate from the hostile environment (e.g., birds). Some animals can remain active but adapt by

- growing thicker fur (e.g., weasels and snowshoe rabbits),
- storing extra food for the coming winter months (e.g., beavers, some squirrels and mice),
- changing their diet to that which is available during the winter (e.g., the red fox normally eats fruit and insects but eats small rodents in the winter),
- using shelters to protect them from the cold.

For others (e.g., reptiles, ground squirrels, and certain bears), migration is impossible and other adaptations are either impossible and/or ineffective as protection. These animals then adapt by means of hibernation.

Hibernation is seen mainly in small animals such as marmots, ground squirrels, chipmunks, dormice, and northern bats whose food supply is very limited or nonexistent in winter. Cold-blooded hibernators include such amphibians as frogs and toads and such reptiles as lizards and snakes that pass the winter with body temperatures that are the same as the ambient temperature (i.e., near freezing). More recently, a tropical primate, the fat-tailed dwarf lemur (*Cheirogaleus medius*), endemic to Madagascar, has also been found to hibernate.

Outside of winter, natural hibernators lacking food and facing other adverse conditions cannot *choose* to hibernate to survive. Indeed, unless an animal is genetically disposed to hibernation or other states of dormancy, it cannot become dormant at will to escape inhospitable conditions.

Some refer to hibernation as "time migration" since hibernation allows the animals to skip over the entire period of the inhospitable winter season and truly "live" only in the periods of plentiful food and higher temperatures that occur outside of winter. Indeed, to the hibernating animal, time passes unnoticed since it is insensible and unaware during winter and becomes active or "alive" only at the end of hibernation.

Interestingly, according to an American legend, the hibernating groundhog (woodchuck) can be used to predict a period of time, namely, the length of the winter season. It is said that the groundhog creeps out of its hole on February 2 of each year (Groundhog Day) and that if the day happens to be sunny and the groundhog sees its shadow, there will be 6 more weeks of winter. On seeing its shadow, the groundhog supposedly returns to hibernation again. If, on the other hand, the groundhog does not see its shadow, it stays above ground, cutting short its hibernation. This is supposed to indicate the imminent arrival of spring, or the end of winter. Of related interest is a 1993 comedic movie by the same name, *Groundhog Day.* It describes a television reporter (a weatherman) who, while waiting to report on the arrival of the hibernating groundhog, becomes "stuck in time" on Groundhog Day. In the movie, time stands still since the events of that day are repeated without end, making it impossible to move on to the next day!

Hibernation is very different from sleep since it involves an extreme reduction in metabolism. For example, a black bear's heart normally beats about 60 times per minute but this is reduced to as little as 5 times per minute during hibernation (about a 90% reduction). The blood pressure of an active mouse varies between about 80 and 120 millimeters of mercury (mm Hg). By contrast, blood pressure in a hibernating mouse varies between about 30 and 50 mm Hg. A hibernating marmot may reduce its breathing from 16 to 2 breaths a minute and its heartbeats from 88 to 15 per minute. Hibernating turtles reduce their metabolic rate by as much as 95%.

Terms like adaptive hypothermia, or the lowering of body temperature to adapt to changes in the external environment; torpor (state of dormancy and inactivity); and suspended animation (temporary suspension of vital functions) are often associated with hibernation.

The Hibernaculum

To hibernate, most animals go into shelters such as burrows, caves, and dens as a buffer from the lethally low ambient temperatures. The temperature of these shelters is normally slightly above the ambient temperature and does not fluctuate as much. This shelter is called a hibernaculum. There is no standard type of hibernaculum. For example, most rodents hibernate in underground burrows. Bog turtles (*Clemmys muhlenbergii*) use hibernacula that include abandoned animal burrows, mud cavities, and the base of tree stumps. Tortoises use underground sites such as burrows excavated in soil or rocky caves. Bats choose a hibernaculum that is not only cold but humid. For example, in winter, the Indiana bat (*Myotis sodalis*) hibernates in limestone caves and also in some manmade shelters, like underground mines. Adders (*Vipera berus*) in cold areas hibernate in clusters in underground areas made by other animals, for example, in abandoned mammal or tortoise burrows. Animals that are not in the wild will even use crawl spaces and basements in buildings.

Most hibernacula must remain at temperatures slightly above freezing (not too cold or too warm), must have a relatively high humidity, must be safe from predators and other intruders, and in some cases must have space for the animal to store food. Indeed, hibernacula are usually dark, protected, and secluded to keep the hibernating animal safe. A suitable hibernaculum is key to the survival of the animal when it is so vulnerable during hibernation.

Length of Hibernation

The period of hibernation may vary, lasting several days or weeks depending on the animal's species, the ambient temperature, length of winter, and the animal's latitudinal location. Woodchucks hibernate in underground burrows from September or October until March (about 5 to 6 months). The fat-tailed dwarf lemur hibernates for around 7 months of each year in tropical winter temperatures that are relatively high.

Typically, whatever the exact length of hibernation, it is generally characterized by periods of sporadic arousals. The intervals between these arousals depend on the animal's size, body temperature, and other internal factors. For example, in one study, hibernating hedgehogs were observed to have 12–18 arousals. The average duration of these arousals was 34 to 44 hours. Some arousals are initiated by external stimuli like noise and are called alarm arousals. Other arousals do not appear to be initiated by any external trigger and seem to be under the control of signals internal to the animal (endogenous signals). Final arousal from hibernation always occurs at the end of winter, and it is believed that this may be controlled by a combination of exogenous (environmental) and endogenous signals that work to prevent the animal from reentering hibernation.

What Initiates/Triggers Hibernation

Entry to hibernation may be triggered by environmental factors such as temperature, day length, and shortage of food. Indeed, animals such as hamsters and chipmunks are sometimes called *facultative* hibernators because they hibernate in response to environmental conditions.

For *obligate* hibernators (e.g., ground squirrels, marmots, and white-tailed prairie dogs), on the other hand, the cycle of storing food, hibernating, and arousing seems to be controlled mainly by a signal or cue that originates internally from the animal itself (an endogenous signal). For example, when the golden-mantled ground squirrel (*Spermophilus lateralis*) is kept in the laboratory under constant environmental conditions (i.e., in the absence of environmental triggers), hibernation occurs just as if it were in its natural habitat. This indicates that environmental triggers (exogenous cues) are not essential for hibernation in this animal and so the golden-mantled ground squirrel can be considered to be an obligate hibernator.

On the other hand, some birds, like the common whippoorwill, enter a hibernation-like state once their food is removed (environmental trigger). Similarly, food availability has been shown to play a major role in the start of hibernation in the Japanese dormouse (*Glirulus japonicus*). At the same time, another environmental trigger, low ambient temperature, does not appear to have significant influence on the hibernation of the Japanese dormouse once there is an adequate supply of food. Hibernation in the desert tortoise (*Gophents agassizii*) also appears to be only weakly influenced by exogenous environmental cues.

Thus, for some animals some type of endogenous signal or cue is the main determinant of entry to and exit from hibernation. It is believed that this internal signal is regulated by a biological rhythm based on a 24-hour cycle (called a circadian rhythm). The onset and end of hibernation in most animals appear to be triggered by both endogenous signals and exogenous environmental cues.

Biological Clocks

The endogenous cue that triggers hibernation is believed to be based on an internal or biological clock. The biological clock is believed to control not only the hibernation of animals but also many repetitive physiological functions in humans, as well as the migration of birds and the flowering of plants. It is also believed that the periodic arousals characteristic of some hibernators are regulated in part by the biological clock. Also, final arousal from hibernation in spring may be triggered partly by the biological clock.

Although it is endogenous, it is believed that the biological clock responds to several external environmental cues, in particular day length or more accurately the photoperiod (the ratio of daylight to darkness). The photoperiod is an exogenous environmental cue that is "sensed" by the animal from certain sensory organs, like the eyes and also from light-sensitive receptors in its brain. The location of the biological clock in animals, its properties, and the mechanisms by which it operates are only now beginning to be discovered. Indeed, the study of biological clocks and their associated rhythms has led to the scientific discipline called chronobiology.

Thus, the timing of the entry into and exit from hibernation may be due primarily to an endogenous circannual (about a year) or circadian (about a day) rhythm with the timing being reset annually by environmental factors such as day length.

Effects of Global Warming/Climate Change

There has been some concern that higher global temperatures may have led to shortened winters that could have a negative effect on animals that hibernate. For example, some research done in Italy suggests that climate change is indeed bringing animals out of hibernation early. This is believed to put their feeding and breeding habits out of synchronization with the environment, causing unusual weight loss and stress in the animal. For instance, one study observed the effect of annual temperatures in southern England (between 1983 and 2005) on the body condition of female common toads (*Bufo bufo*). This study suggested that "partial" hibernation (early emergence from hibernation) occurred in the female toad as a result of the mild winters experienced during those years. It is thought that this contributed to a decline in the bodily condition of the toad, which negatively affected its survival.

Another study of the effect of temperature change on several traits of over 1,000 temperate-zone animal species worldwide revealed that springtime events (e.g., blooming of flowers, laying of eggs, and the end of hibernation) now occur about 5.1 days earlier per decade on average. Some studies on marmots in Colorado also show that they are ending their hibernations about 3 weeks earlier than they used to in the late 1970s. It has been reported that dormice now hibernate 5–1/2 weeks less on average than they did 20 years ago. Reports indicate that some bears in Spain (slightly different genetically from bears in other parts of the world) have stopped hibernating altogether, remaining active throughout recent winters. Research and debate continues on climate change and its effects on animals' biology and behavior, including hibernation.

Artificially Induced Hibernation

There has always been interest among medical researchers in the chemical induction of hibernation. The potential benefit of putting trauma patients into hibernation and giving doctors more time to repair severely damaged tissue is just one advantage of artificially induced hibernation in humans. Science fiction writers have also explored the possibility of preserving human life in a reversible state of so-called suspended animation. Supposedly, one could exist in such a state for several years without aging, without the need for food and the elimination of waste, and reawaken unaffected by a journey through space of many years to another planet. Inducing artificial hibernation in humans (even in fiction) is therefore potentially a way of "buying time."

Hibernation cannot be induced in nonnatural hibernators by manipulating the environment, so researchers have searched for a possible blood-borne chemical that could induce hibernation. It has been discovered that a serum extracted from hibernating animals such as the woodchuck, when injected into active animals, can induce a hibernation-like state. This serum contains a substance called the Hibernation Induction Trigger (HIT). Experiments with hydrogen sulfide have also shown potential for inducing a hibernation-like state in nonhibernating animals.

Other Types of Hibernation

The term hibernation is now used widely outside of the life sciences to refer to any period or state of temporary dormancy or inactivity. For example, it is used in computer technology to refer to the state of dormancy that can be achieved by powering down a computer while retaining data about running programs and the status of the input/output devices. When the computer resumes from the state of hibernation (on powering up), it reads the saved state data and restores the system to its previous state.

Companies have been said to go into hibernation as a survival strategy to avoid closure (analogous to animal hibernation, the business operations might be reduced drastically to maintenance levels until, for example, brighter market conditions emerge). Projects that are temporarily dormant have sometimes been said to be placed "on ice" and "in hibernation." The term hibernation is also sometimes used for any temporary loss in function as seen, for example, in organs in the human body.

Hinduism, Mimamsa-Vedanta

Among the six principal schools that developed in the Brahmanical traditions in India, Mimamsa and Vedanta form the most recent group, the others being Nyaya, Vaisesika, Samkhya, and Yoga systems. These two schools, that is, Mimamsa and Vedanta, are also known as Purva-Mimamsa and Uttar-Mimamsa. Founded by Maharshi Jaimini and Maharshi Samkara, respectively, these schools develop their theories of time in a unique way. Remaining faithful to the core thought of the Upanishads, namely the reality of the immutable Brahma, they explain the phenomena of change in diverse ways.

The Purva-Mimamsa school has two sects, one known as Bhatta or Kumarila Mimamsa, propounded by Kumarila Bhatta, and the other known as Prabhakara Mimamsa, established by Prabhakara Mishra. The two sects differ somewhat in their treatment of time.

In the Jaimini Sutra the concept of time is discussed in connection with action. Some element of time is associated with all actions. Action is in a way determined by time. The Mimamsa school bases its philosophy on the Vedic hymns. According to these, while interpreting Vedic hymns, if the hymns are correctly pronounced, they refer to the laws of time or life. But it is also said in the Jaimini Sutras that time is not the cause of the result of action. Result is due to the effort.

The Vedas never refer to time as the sole cause, for a result never comes simply due to the passage of time. But it is true that sometimes if after several sincere efforts, one fails to achieve results, one can attribute the failure to time. In ancient thought time is associated with decay, death, and failure. Time changes our position. But the Mimamsa text clearly points out that everything happens due to the impelling force, and time is not connected with it. The concept of change is associated with both nature and time. The concept of time is associated with any new being. But time itself is immeasurable as it is without beginning or end. It is through the instrument of intellect that we receive the idea of time. For the purpose of our understanding, the seers have divided time into *yugas, manvantaras,* and *kalpa.* These are nothing but the exercise of our mental faculties. When we analyze the etymological meanings of these terms, the point becomes clearer. The word *yuga* is derived from *yuj,* which means "to fix or concentrate the mind." The word *manvantara* is derived from *manu,* which is the same as mind. Similarly, one of the meanings of kalpa is research or investigation. And the word *kala* for time is itself derived from *kal,* which means to perceive or consider. So, it might be said that the idea of time involves a series of functions of the intellect or the mind.

It is mainly the orderly arrangement of objects or the succession of events that gives us an idea of time. The appearance of a new object in nature reminds us about the role of time.

Though the Mimamsakas are known as theists and God plays a supreme role in their systems, still time cannot be personified as God, as God creates and sustains the universe. But time does not play the role of creator and sustainer, although sometimes it is treated as the greatest destructive force.

After life begins on this earth, time starts acting upon everything of the universe, but time itself remains unaffected. Therefore it is said to exist for other things and not for itself. Like the *prakriti,* or nature, of the Samkhya system, time remains unaffected throughout its functions.

For our practical purposes we divide time into segments but time itself is a continuous whole.

Time is like butter that is beginning to separate out of cream; it partakes of the nature of both the butter and the cream, yet the two can be separated. Like the endless chain of desires, time flows continuously. It has been said that when the mind begins to function, desire arises, hence the idea of time is associated with desire.

The Mimamsa school follows the sacred text known as the Gita. In the Gita it is stated that the number 12 refers to time. This number constitutes the basis of the calculation of the time of day and night, the months of the year, as well as the great ages of time, all of which are multiples of the number 12. The Mimamsa text refers to *dvadasa-satam,* which may mean both 112 and 1,200. These two numbers refer to the passage of time. There are four yugas: *Satya, Treta, Dvapara,* and *Kali.* The entire duration of these yugas make a Manvantara, and a thousand yugas constitute a kalpa. The duration of these four yugas is said to be 1,728,000 years, 1,296,000 years, 864,000 years, and 432,000 years, respectively, of human time. The above figures are nothing but multiples of 1,200, which may be said to refer to prakriti, or time. In the Mimamsa text, the number 12 plays an important role, as it represents time or prakriti.

Bhatta and Prabhakara Schools Compared

Both of the schools of Mimamsa (Prabhakara and Kumarila) admit that substance is that in which quality resides, and they treat time, like space, as substance.

Kumarila, in his commentary titled *Slokavartika on Sabara-bhasya,* an important text of the Mimamsa school, says that time is one, eternal, and all-pervasive. But although time is all pervasive, it is conditioned by extraneous adjuncts for the purpose of empirical usage. And this is the reason that there are various divisions and subdivisions within all-pervasive time. *Tantravartika,* another commentary in prose on *Sabar-bhasya,* describes time as eternal like the Veda. Not only Kumarila but Prabhakara, another philosopher of the Mimamsa school, also treats time as one of the eternal substances.

Regarding the perceptibility of time, the two schools of Mimamsa (Bhatta-Mimamsa and Pravakara-Mimamsa) differ in their viewpoint. The Bhatta school held that time is perceived, whereas the Pravakaras joined the Nyaya-Vaisesika system in maintaining inference to be the valid means for knowing time. Parthasarathi Misra, a noted Bhatta-Mimamsaka philosopher, in his work *Sastradipika* points to the fact that all perceptual cognitions also include the duration of the perception. In our everyday dealings we express such statements as "we are perceiving the pot from the morning . . ." And this statement clearly reveals the fact that time is perceived. While recording a statement, we always use such expressions as "now," "then," and the like. Such expressions would be meaningless if time were not also perceived along with the perception of the object. These words refer to the time-content of the perception itself. The Bhatta-Mimamsaka wants to stress that the temporal dimension of all our perceptions would remain unaccounted for without the contention that time is amenable to perception. The Nyaya-Vaisesika philosophers deny that time can be said to be perceived, as it has no perceptible qualities such as colors and form. It can only be inferred.

But the Bhatta-Mimamsaka retort that absence of color in time does not prove that time is imperceptible. Possession of a quality like color is not a criterion of perceptibility. Thus the contention of the opponent suffers from the fallacy of false generalization. However, the Bhatta-Mimamsakas acknowledge that time as such is never an object of perception, but it is perceived always as a qualification of perceptible objects. Therefore time is perceived as a qualifying element and never independently of the perceptible object. This is why we perceive events as slow, quick, and so forth, which involves a direct reference to time.

In *Manameyadaya,* a notable Mimamsa work, one of the exponents of Bhatta-Mimamsa, Narayana, refutes the claim of Nyaya-Vaiseseka that time is inferred on the basis of such notions as simultaneity. Narayana expands his view with the following example: In our everyday life we experience such events as "Devadatta and Yajnadatta arrived simultaneously" or "Ram arrived late." Here the question is whether such awareness, received through perception, can be denied to have time as its essential component. The point that emerges is that such direct, immediate awarenesses as simultaneity or lateness cannot be ascertained, as in the above examples, through anything but sense-perception. "Devadatta," "Yajnadatta," and "Ram" are related directly to time, and the latter is perceived along with the substances that it qualifies.

Prabhakara also treats time as one of the eternal substances. According to Prabhakara, space and time cannot be perceived as they cannot be seen or touched. Prabhakara considers some degree of magnitude along with color and touch and other such qualities as a necessary condition of proper sense perception. Time, though large, is not perceptible because it is devoid of color and touch.

Vedanta

The Brahmanical tradition finds its full expression in the system of Vedanta. The system follows the literal teaching of the Brahma Sutra, where a complete identity or oneness is shown between the world and the Brahman, hence it denies the reality of the finite world of time and space. The two main commentaries of the Brahma Sutra are the following: Samkara-Bhasya, propounded by Maharshi Samkara, and Sribhasya, propounded by Maharshi Ramanuja. Both of them believe that Reality is non-dual, but their interpretations differ. The school of Samkara is known as *Advaita-vedanta,* and the school of Ramanuja is known as *Visistadvaita-vedanta.* In the school of Advaita-vedanta, the problem of Creation is reduced to a problem of appearance, whereas in the Visistavaita school of Ramanuja, the world is conceived as the body of God. The concept of time is discussed here mainly from the Advaita-vedanta standpoint of Samkaracharya. The conceptual framework of this school has the unique characteristic of expressing its position with the single dictum, "Reality is the-one-without-another." Here the concept of being is treated as timeless, involving the notion of time as appearance. This nondual nature of Brahman (reality) reduces all duality (difference) to a problem of appearance. In this metaphysical system there is no place for the concept of objective real time. To accept time as real is to invite pluralism. But this view cannot be accommodated in the system of Advaita-Vedanta because "Reality is one-without-a-second." So the question arises, What will be the status of time here?

To understand the status of time, it is necessary to discuss the notion of causality of the Vedantins that is known as Vivartavada. In this theory, the effect is characterized as "no-other," that is, *ananya,* to the cause. In his commentary on the Brahma Sutra, Samkara brings out the importance of the term ananya as the effect being no-other in relation to the cause. This is the kernel of the vivartavada of the Advaita Vedanta. In the Vedantaparibhasa, an important work on the Vedanta glossary of technical terms, the significance of the term *vivarta* is explained. The term vivarta is to be understood by contrasting it with the term *parinama.* When the cause and the effect are taken to be realities with the same status, the effect is designated as parinama of the cause; for example, prakriti and its different aspects evolve in Samkhya system. But if the cause and the effect cannot be given the same ontological status, it is termed vivarta, as in the case of the world as effect in relation to its cause, Brahman, the Real, in Advaita Vedanta. Here the effect is indeterminable, related to neither sameness nor difference. The effect is nothing but the *appearance* of the cause—the effect has no separate existence of its own other than a difference of name and form, just as the earthen jug cannot have any reality apart from the clay, its material cause. The Advaita Vedantin asserts that no change or modification can be ascribed to that which is real. In other words, change can never be granted a separate ontological status under any circumstances.

The process of Creation as discussed in the Brahma Sutra shows that the world is in time. And time is characterized by succession and sequence. The steps shown in the creative process involve succession. This succession implies that the world must be in time. The creation and the dissolution of the world are a temporal series.

The Vedantins believe in the rebirth of the soul. The experiences gathered by the finite soul in each birth and death are events in time. The Vedanta schools agree unanimously on one point: that the liberated soul is beyond the domain of the temporal world. Therefore, finite souls live, move, and have their being in time. But here a question arises: How can an eternal and changeless Brahman be held to be preceding the world? Precedence, succession, sequence—these are all time relationships. If Brahman precedes the world and brings the world into existence at a certain point of time, Brahman cannot be called eternal and cannot be beyond time. In the Vedanta texts the word *eternal* is used in different senses. Sometimes the word *eternal* means existing for an unending span of time. Sometimes this word is used in the sense of being beyond time. In other places it is taken as transcending time yet somehow including it. There is a distinction between self-contained Brahman and Brahman-who-creates-this-world in the Vedanta texts. But this distinction is apparent, not real. The temporal order of the world is in Brahman. Thus Brahman is beyond and yet somehow includes time.

In fact, the Advaita Vedanta reduces the problem of creation to a problem of appearance. Just as the earthen jug, which has a distinct name and form, does not have an existence independent of the "clay" from which the jug is made, similarly the world as effect has no independent existence without its cause: Brahman. The Advaita Vedantins do not accept Brahmaparinamavada, a theory where the world is conceived as a real transformation of Brahman. The Vedanta school maintains Brahman as the cause, but cannot accept any transformation or modification of the cause. The empirical world is entirely dependent on the self-existent Brahman, having no reality of its own. Brahman is the indispensable cause of the world-appearance. *Maya,* or illusion, explains the existence of this temporal and spatial world. But it should be pointed out in this connection that the idea of appearance does not imply that the world is merely a subjective dream. Samkara, in his commentary on the Brahma Sutra, refutes the Buddhist school of subjective idealism by saying that the world is empirically real. The idea of the false appearance of the world is intended to disclose its entirely dependent status, that is, it is not real per se. Brahman as real per se as cause of the origin, sustenance, and destruction of the world points to the formulation of the idea of being as timeless as the very presupposition of the temporal. There are two types of definition of Brahman as cause of the world in the Advaita Vedanta texts: one is *tatasha-laksana,* the accidental or modal definition; the other is *svarupa-laksana,* or the nonrelational definition. The modal definition indicates Brahman as the ground of the experienced world as it appears to be. But the Advaita-Vedanta advocates a nonrelational definition of Brahman as *sat-cit-ananda swarupa* (being–consciousness–bliss). The temporal world as effect is not ontologically real, but Brahman as its foundation is self-existent. In Advaita-Vedanta, Brahman is characterized as nontemporal, nonspatial, and noncausal. Time, space, and causality are all categories of the empirical world. These categories presuppose pluralities that are the products of our ignorance or *avidya.* It is because we are veiled with ignorance that we experience this plural world. Brahman transcends these categories and is the timeless Reality. Thus Brahman is beyond the spatiotemporal sequence of multiple events and things.

Sri Harsa, an ardent follower of Adaita Vedanta, raises the question whether such time distinctions as past, present, and future are integral or not integral to time as such. If these distinctions are integral to time as such, then the notion of the unity of time has to be given up. On the other hand, if one upholds the unity of time as essential and the differences of time-forms as inherent in it as its threefold nature, then the designations of past, present, and future could be made at random for want of a strict basis for such usages. This is to say that one cannot accept the differences of time-forms as integral to one time, either. But if it is said that it is due to the sun's motion that time divisions arise, Sri Harsa also finds that to be equally untenable. He holds that the solar motion cannot account for the determinations of the different time forms, since it is used as the common criterion for the divisions of all three time forms—past, present, and future. It is said that the same qualifying factor—the solar motion that distinguishes the past day from the present and also distinguishes the present day from the future—is not a basis for valid argumentation. In this way Sri Harsa rejects the reality of time.

Not only Sri Harsa but also Citsukha, another great exponent of Advaita Vedanta, in his important work *Tattvapradipika,* has discussed the problem of time thoroughly. While refuting the existence of time, Citsukha argues that neither perception nor inference can establish the reality of time. The ontological reality of a substance can be established through perception only if the substance in question can be said to be perceived by vision or touch. But as time is without form and is intangible, sense perception cannot be the source of knowledge. Time cannot be perceived even though the mind works only in association with the external senses. It cannot even be inferred in the absence of perceptual data.

Again it is possible to point to the existence of such mental states as happiness or sadness, which are known through introspection and need not be first known through sense perceptions. Could the existence of time be established in a similar way? But Citsukha rules out this possibility, as it is possible only for facts that are subjective, but time as an objective category of existence cannot be thus established.

Time cannot be inferred as the substratum of the notions of priority and posteriority, succession and simultaneity, quickness and slowness, as these notions are not associated always and in all places. It may be argued by the Naiyayikas that the entity that establishes relations between the solar vibration and worldly objects is called time. But Citsukha replies that all-conscious self is the cause of the manifestation of time in things and events; therefore it is unnecessary to assume the existence of a further entity called time. The notions of priority and posteriority are associated with a larger or smaller quantity of solar vibrations. So here also it is not necessary to admit time as a separate category.

Concluding Remarks

In conclusion, it may be noted that the Brahmanical tradition expresses its conception of being in its radical form in the Vedanta system, rejecting the pluralistic model. The system advocates a philosophy of nondualism and focuses on the reality of the unchanging eternal Brahman as the one and only Reality. The concept of time plays a phenomenal role without any ontological reality.

Hinduism, Nyaya-Vaisesika

The Nyaya-Vaisesika schools of thought founded by Maharshi Gautama and Kanada, respectively, advocate a plural, realistic worldview. These schools focus on the reality of time as vital to their total conceptual framework. Their philosophical outlook regarding the role of time is distinctly different from that of other schools of the Indian tradition.

Time, in the context of the Nyaya-Vaisesika philosophy, has been studied in its various aspects. The question of its existence and how it is related to different ontological issues like causality, motion, and space are all highlighted in the Nyaya-Vaisesika system. This system believes in the theory of Creation. Kala, or Time, is considered as the eternal, unique, all-pervading background of the creative process. All events derive their chronological order through time. But time possesses no specific physical quality like color and thus cannot be an object of external perception. Neither is it perceivable internally, as the mind has no control over external or internal objects independently of a physical sense organ. But the question of its existence is arrived at by a series of inferences. The notions of priority (*paratva*) and posteriority (*aparatva*), of simultaneity (*yaugapadya*) and succession (*ayaugapadya*), and of quickness (*ksipratva*) and slowness (*ciratva*) constitute the grounds of inference for the existence of time.

It is a recognized fact that priority and posteriority are related with the movement of the sun. When using the term *now,* it is natural to refer to the motion of the sun above or below the horizon by so many degrees. But a pertinent question is raised by the Nyaya-Vaisesika philosopher: How can any object be related at all with the motion of the sun? It is not possible to establish any direct relation of inherence, as the motion of the sun inheres in the sun alone, and not between the object in question and the sun, which are far apart. There must be a connecting medium that joins the two and that is capable of transmitting the quality of one to the other. This fact leads to the inference of time. Regarding the question of whether time is perceived or inferred, there is a philosophical debate among the Indian realists. The main voice in denouncing the view of the Nyaya-Vaisesika is the Bhatta-Mimamsaka school. In reply to the Nyaya-Vaisesika view that time cannot be said to be perceived as it has no sensible qualities such as color and form, the Bhatta-Mimamsakas maintain that sensible qualities are not the criteria of perceptibility. However, they do acknowledge that time as such is never an object of perception, though it is always perceived as a qualification of sensible objects. It is for this reason events are perceived as slow or quick, which involves a direct reference to time. The Nyaya-Vaisesika philosophers answer that a directly perceived time would point to only a limited, divided time, which is not absolute time but conventional temporal time. Sridhara in his *Nyaya-Kandali* and Jayata Bhatta in his *Nyaya-Manjari* take up the issue in a brilliant manner. According to them, time cannot be established as objects of ordinary perception, as time does not possess any finite dimension.

There are certain typical terminologies in every Indian philosophical system that are unique within their field; the Nyaya-Vaisesika system is no exception. Besides normal perception, extraordinary perceptions are also accepted by this school. One of the extraordinary perceptions is known as *Jnanalaksana*. This is the type of perception where the perceived object is given to the senses through a previous knowledge of it. For example, when someone says, "I see the fragrant sandalwood." Here one visualizes fragrance due to a prior knowledge of it from past experience. Similarly, the perception of "the present pot" is composed of two elements. "The pot" is an object of ordinary perception, whereas the time element indicated by the word *present* is derived from previous prior knowledge of time, resulting in the extraordinary perception of "the present pot."

So the sense perception of time as a qualifying element of the object is analyzed by the Nyaya-Vaisesika philosopher as based on the previous inferential knowledge of time. Moreover, the Nyaya-Vaisesika system believes that time must be of unlimited magnitude as it has to determine the priority and posteriority of all finite substances of the world. In other words, it must be a ubiquitous substance. Time is also conceived as *nimitta karana* or the instrumental cause of all objects of the world. This causation also leads to the point that time is eternal.

Kala (time) is treated in the Nyaya-Vaisesika system as the substratum of motion. The statement "I am at present writing" clearly points out that time is the substratum of objective motion. Not only is time the substratum of objective motion, it is the cause of the origination, maintenance, and destruction of all objects of the world.

Time and Causality

In Nyaya-Vaisesika literature, the role of time comes to the forefront in discussions of causality. For any causal operation the idea of absolute time is accepted as a necessary presupposition. The distinction between the eternal and the contingent is clearly mentioned in their writings. An object that is ever-present cannot be amenable to creation or destruction. The contingent is defined as that which does not exist prior to its creation and ceases to exist after its destruction. An object like *akasa* (i.e., ether) is never nonexistent whereas an absolute nonentity like a hare's horn is ever nonexistent. Any causal operation is necessarily an event in time. No event is conceivable without time as its *adhara* or receptacle. According to Nyaya-Vaisesika philosophy, to deny time an objective reality is to face a static universe where there is no room for any change or movement.

The theory of causality known as *asat karyavada* presupposes time in the Nyaya-Vaisesika system. The theory is so called because the effect is conceived as *asat,* that is, nonexistent prior to the causal operation. Cause is defined as that which is an invariable and necessary antecedent to an event. Here, the idea of antecedence has an immediate temporal reference. The idea of time always follows when it is said that the effect succeeds the cause.

Another characteristic of time is that, though time is a *dravya (*substance) it does not presuppose any substratum for its existence, as it is something undivided and eternal. Time is *svatantra,* or independently real. As time is all-pervasive, it has no form. The main argument that the Nyaya-Vaisesika proposes is that time, being a necessary condition of all movement and change, must itself be free from general attributes.

Divisions of Time

But here a question arises: If time itself is free from general attributes, are divisions of time real? The Nyaya-Vaisesika does accept the conventional time divisions. Generally, time is divided into past, present, and future. This division does not affect the inherent nature of time. These conventional time divisions can be explained with the help of limiting adjuncts, which are of finite duration. It is only with relation to events that time takes on these distinctions. Saying that something is happening refers to an event that has already begun but has not yet ended. Similarly, the past is the time related to an event that completed its cause of action, and the future is related to an event that has yet to begin. It is only the actions that are labeled as past, present, and future. Real time is never affected by these *upadhis,* or external adjuncts, namely, different solar motions.

This conception of absolute time in the Nyaya-Vaisesika system has been criticized by all the schools of Indian philosophy. Here is the view of one of the major systems: The Advaita Vedanta school maintains that this argument is not plausible because all the three divisions of time are related in the same way with the same solar motion. For example, a particular day is understood as the present with reference to a particular solar motion. But it must be admitted that the same solar motion is responsible for past and future days. The day referred to above is understood as present on the day itself, as past on the days that follow, and as future on coming days. Here the three time determinations, namely present, past, and future, have the same conditioning factor, namely, solar motion.

The Nyaya-Vaisesika answer is that the above position has come about due to the absence of certain necessary qualifications regarding relationship. When the time of an event is in "actual" relationship to solar motion we cognize it as present. A thing is cognized as past when the particular relationship "has been" and "is no more," and when the relationship in question "will be" and "is not yet," it is recognized as future. But the vedantin does not accept this position and says this argument is merely tautologous. The terms *actual, has been,* and *will be* are synonyms of present, past, and future, respectively.

In answer to his opponent, the Nyaya-Vaisesika suggests a modified definition of time division. The time that is conditioned by a particular action is present in respect to that action alone and not in relation to other actions.

In fact, the criticisms that the opponent offers are applicable only to the time division of the Nyaya-Vaisesika system. But time division is not inherent in the nature of time; hence it does not at all affect time-in-itself. Thus the criticisms do not really affect the reality of absolute time. These time divisions belong only to the events that are in time. The Nyaya-Vaisesika does not agree that the time series is the "schema" of the understanding and is formed by the conceptual fusion of discrete movements. The reason behind this view is the following: It is not possible to encounter the objective existence of a momentary entity. "The jar exists for many moments." This perceptual judgment cannot prove the objective existence of moment. It is a common experience shared by us all that a moment is supposed to vanish just after its contact with the sense organs; it cannot synchronize with perceptual judgment. A question, therefore, arises: Is not the use of the term *moment* superfluous? The Nyaya-Vaisesika system maintains that it is not superfluous, it is part of the whole cognition procedure. Moreover, every cognition presupposes a determinant datum, hence a particular datum in this case should be pointed out. It is said that the datum in this case is a particular motion and the pre-nonexistence of disjunction caused by it as the determining factor of motion. Each of the moments covers a definite duration; hence they cannot separately be the datum. These two, taken together, form the datum of cognition.

Moment, Time, and Space

In the *Prasastapadabhasyam,* one of the major authentic books of the Nyaya-Vaisesika system, the unique character of time is brought out in relation to space. Time has only one form of mensuration. The point is elaborated by saying that the temporal order of events is such that it does not allow for reversibility, whereas the spatial order does allow that. Thus, in the realistic framework of Nyaya-Vaisesika, another question crops up: How are they related? It is said that every cognition acquires them at the same time; hence cognition itself is the connecting link. The moment itself is the datum of such cognition. Therefore the concept of moment arrives indirectly in the framework of cognition. A moment is the point of time that refers to the final phase of cause and the initial phase of effect. Vallabha, a famous commentator, in one of his books defines moment as that intervening span of time that comes between the completion of the totality of caused conditions and the production of effect. This discussion reflects the realistic attitude of the Nyaya-Vaisesika system. These two—space and time—are characterized as *niravayava* (noncomposite), *avibhajya* (indivisible), and *vibhu* (ubiquitous). All objects are in space and time, but space and time cannot be said to be contained in anything.

This traditional view of absolute time is questioned by the later school of the Nyaya-Vaisesika system. Raghunath Siromoni, one of the famous philosophers of the Nabya-Nyaya system, challenged the entire conceptual framework of the pluralistic metaphysics of Maharshi Gautama. In his book *Padarthatattvanirupanam,* he criticized the traditional understanding of time. He does not find enough justification for accepting these two all-pervasive substances that require adjuncts in order to account for spatial and temporal divisions. He wants to identify space and time with God, who is also characterized as an all-pervading substance. Regarding time, he gives up the notion of absolute time and introduces a new category called *ksana* (moment). But he rejects the notion of moment in relation to motion as inadequate. Instead he sets up a new category consisting of things that are not motions but that share the universal repeatable property of momentariness.

This version of Raghunatha Siromani was not approved, however, by the later adherents of the school. In fact, the idea of absolute time is integral to the whole fabric of Nyaya-Vaisesika thought as all the concepts are woven together against the background of this particular concept; that is, absolute time. Therefore, in the Nyaya-Vaisesika system, time is a reality per se, the very presupposition of the reality of change.

Hinduism, Samkhya-Yoga

The Samkhya-Yoga system is one of the oldest Brahmanical traditions of India. Founded by Maharshi Kapil and Maharshi Patanjali, respectively, these two schools share a basic ontological structure, with some subtle differences in their treatments of time.

The Samkhya system rests on a dualistic metaphysics, tracing the whole course of the universe to an interplay of two ultimate principles—*Purusa* and *Prakriti.* The dichotomy of matter and consciousness is expressed by these two terms; Purusa is the unchanging principle of consciousness, whereas Prakriti is the ever-changing principle of matter. The Yoga system shares this metaphysical dualism of Samkhya but whereas the latter is atheistic, the former is theistic. Both of them, however, deny the Nyaya-Vaisesika view of absolute time.

Time, Causation, and Change

The concept of time in the Samkhya-Yoga system can be grasped only in the framework of their metaphysical thought, along with their theory of causation termed as *Satkaryavada.* This theory explains the relation between Purusa and Prakriti in a unique way. Everything that is manifest is dependent on a cause. This causal dependence shows the contingent character of the objects. It is not possible to posit any entity without a cause. In the Samkhya system the understanding of the manifest as caused leads ultimately to the postulation of Prakiti as the unmanifest, uncaused principle. Prakriti is dynamic; it is matter that evolves ceaselessly. It is the formal, material, and instrumental cause of the world. This Prakriti consists of three qualities, or *gunas: sattva,* as something illuminating; *rajas,* as the active component; and *tamas,* as the restraining forces. These three gunas, through mutual cooperation, create this objective world.

The *Samkhya-Karika* of Isvarakrisna contains a detailed discussion regarding the change and origination of the 25 categories, but what is interesting is that nowhere is time recognized as a separate category of existence (*tattva).* In fact, time is taken as an aspect of concrete becoming. The Samkhya system does not recognize any conception of time as independent of change. Change is not understood in abstraction, but as a concrete becoming.

The Samkhya recognizes that the principle of change is ultimate, and so this principle cannot be derived from any fixed principle. The heterogeneous categories of creation with all its varied aspects presuppose always a primordial movement that remains even in the state of cosmic dissolution. It is because of the interplay of the gunas (qualities) that Prakriti is always in motion. In his *Samkhya Karika,* Vacaspati Mistra, the famous commentator, remarks on this ever-changing nature of Prakriti. There are two types of manifestations of Prakriti, *Sadrisaparinama* (homogeneous manifestation) and *Visadrisaparinama* (heterogeneous manifestation). Though no unique object arises from the homogeneous manifestations of the gunas, as they do not mix with one another, yet the process of self-production that is sattva giving rise to sattva, raja giving rise to raja, and so on, continues. The gunas never remain unmodified, even for a moment, as the very characteristic of the gunas is dynamicity. Creation of varied objects is possible due to the heterogeneous movements of Prakriti. This unceasing, ever-active nature of Prakriti points to the principle of change. And this principle of change is nothing but time. Some scholars, such as Madhavacharya in his commentary on *Parasara Samhita,* have characterized Prakriti as the very personification of time.

Here it may be asked whether the process of change is enough to account for time-experience. The Samkhya replies in the positive. Time-experience is totally dependent on the duality of Purusa (consciousness) and Prakriti (matter).

This system rejects the idea of time as a receptacle, advocated by the Nyaya-Vaisesika philosophers. Here the process of becoming as a movement from the potential to the actual is identical with the causal process. The notion of empty time is rejected as merely a thought construction. In other words, the reality of change does not necessarily imply a conception of time apart from the changing material.

In *Samkhya Karika,* Vacaspati Misra observes that it is not necessary to postulate an absolute time for the explanation of action, solar motion, and so on. The temporal phases can be explained with reference to the creative movements of Prakriti.

The concept of concrete becoming is primary. In the state of cosmic dissolution, Prakriti is to be taken not only as a principle of unconscious matter but also as the principle of time itself in its transcendental aspect. In the conception of dynamic Prakriti, the Samkhya system combines both time and matter in the same principle.

Vijnanabhiksu, a noted Samkhya commentator of the 16th century, advocates a different view. In his *Samkhya Pravacana Bhasya,* he maintains that time is nothing apart from the ubiquitous ether or akasa, which is an evaluate of Prakriti. Limited space and time are ether or akasa itself perceived as space and time by limiting adjuncts. The same limiting adjuncts, which are said to account for time-divisions, can do so with reference to akasa, making it unnecessary to postulate time as a separate ubiquitous substance called time. Aniruddha, another noted Samkhya commentator, in his *Samkhya-Sutra Vritti,* also advocates that limited time and limited space are really ether (akasa) conditioned by upadhis (limiting adjuncts) and hence are included in the unified entity of the ether.

In fact, when Vijnanabhikshu consigns the status of space and time to the level of Prakriti itself, he is merely pushing the realistic dualism of the Samkhya to its logical limit. In the Samkhya system, Prakriti is taken as the rootless root of all, and this is the reason for including everything, even time, as part of Nature or Prakriti itself.

In the *Yoga-Sutra* of Patanjali, time is seen as instant. The Yoga school shares the basic ontological structure of the Samkhya. The Yoga system develops its specific stand on the reality of the instant (*ksana*) and the merely subjective construction of sequence (*krama*).

"Sequence" or krama is the temporal succession of forms of the same object. This sequence is broken up into infinitely short instants (ksana). If the flow of time were absolutely continuous, no change could ever happen. But at each moment in time, a subtle, imperceptible change takes place; this imperceptible change is perceptible only to the Yogin, and it is the accumulated effect of these minute changes of which common people become aware. This theory has its modern parallel in the conception of time not only as objective and relative but also as a continuous phenomenon.

The Yoga-Sutra focuses on the three modes of immanent change as the *dharma parinama, lakshana parinama,* and *avastha-parinama*. The Yoga system, like Samkhya, holds that change is incessant in the dynamic Prakriti—the ultimate substance, or *dharma*. When the change is perceptible as a charge of *guna* (quality) in an object, it is called *dharma-parinama. Laksana parinama* directly involves the notion of temporal phases (past, present, and future). The potential is the future state, the manifested is the present, and what has happened is the past phase of the thing. *Avasta-parinama* is that aspect of change that deals with the notion of new and old. This can be explained with an example. An earthen jug is made from a lump of clay. The change of quality through the different stages of the processing of the clay constitutes its dharma-parinama. When it is said that the clay that is at present transformed into a jug was in its past only a lump, it refers to the laksana-parinama. This jug, whether new or old, is known as *avastha-parinama.* The clay remains the same, though the shape changes. This theory of change of the yoga system coheres perfectly with the Samkhya Yoga metaphysical framework. The point that emerges here is that the main substance (*dharmin*) remains the same throughout the three stages of past, present, and future, and the temporal changes are ascribed to the external aspects or qualities of the substance. How does this change in time occur? This is answered by the third type of change, that of the *avastha* (condition) of a thing. Time is a succession of individual moments that imperceptibly alter the condition of the jug; this is the well-known process of decay or aging.

If we substitute consciousness for clay in the above example, we find that emergence and restriction are the forms or dharma of consciousness, each being connected with the three segments of time—past, present, and future—and experiencing its own growth and decay.

The concept of instant (ksana) plays a very important role in this system. As discussed earlier, the concept of time is explained as instant here. The *Yoga Bhasya,* a notable commentary on the *Yoga-Sutra* by Vyasa, holds that the whole universe undergoes change in a single moment. It is said that just as the atom is the minimal position of matter, so the moment is the minimal duration taken by an atom to change its position.

In the Yoga metaphysical structure, a discrete view of time is advocated, over against the concept of time as unitary and as an independent category of existence. This system holds that the idea of time as instant is objectively real, but the idea of time as duration, (e.g., day, month, year) is a mental construct. These are ideal representations. In the *Yoga-Bhasya,* the idea of the reality of instant is recognized. In fact, the idea of time as a continuum or as a substance is unreal for yoga. Time is *vastu-sunya* (unreal) as a substance but time as instant is real (*vastu-patita*). According to the Yoga system, the idea of sequence can be formed only when two moments exist simultaneously. But in reality, two moments cannot and do not occur other than successively. What we experience is always the present, because the past (earlier) and the future (later) moments have no objective reality. In the *Yoga-Sutra,* Vyasa clearly states that the moment is real, and that the idea of a unitary objective time, whether as a collection of moments or as an objective series, is a subjective representation.

Being and Becoming

The idea of time as instant does not hold true of being. In this system, being is not instantaneous. As it was remarked earlier, the substance or being remains the same, persisting through the changes. In the Yoga system, the concept of becoming presupposes the substratum of Prakriti that continues and supports the process of evolution. Not only that, in the Yoga system, the root nature of consciousness is unchanging and unchangeable. The Yoga system recognizes the self as timeless.

Language

From the perspective of philosophy of language, the concept of time plays a distinctive role in the Yoga system. Patanjali in his *Mahabhasya* points out that time is the basis for the tense distinctions of verbs. Here a very pertinent question arises: What accounts for the tense distinctions of verbs? Despite the same verbal root, a word may be used in various ways in the sense of past, present, and future. An analysis of the nature of verbs is always associated with the concept of time. In the *Mahabhasya* of Patanjali one comes across the idea of time as that in association with which bodies grow and decay. Furthermore, the concepts of day and night are described as possible due to the movement of the sun in connection with time.

From the above discussion, it becomes clear that though the Samkhya-Yoga systems share a basic common metaphysical structure, their treatments of the concept of time are not similar. Both of them reject the concept of absolute time, yet in dealing with time, the Samkhya system accepts Prakriti as time personified, whereas the yoga philosophy explicitly advocates a discrete view of time.

Following Professor K. C. Bhattacharya, an eminent Indian philosopher, an explanation of the above fact may be given. It is true that in both the systems time is not admitted as a separate *tattva,* or category. Time in both is concrete becoming, and this becoming is not an event in time. Here becoming, or *Parinama,* may be understood as the cause turning up its own limitation or as the limited effect having got manifested. In the former view, the real objective fact is the act of the cause, its act of production, the succession of cause and effect being only a retrospective construction. In the latter view, the real fact is the antecedence of the cause to the effect, the prior becoming of the effect, but the causal act as the initial moment of this becoming is but an abstraction. Therefore to Yoga that presents the former conception, time is real as the causal act, the initial moment of this becoming. To Samkhya, the effect being preexistent in the cause is never turned up, so that the time relation of sequence alone is real time.

In conclusion, it may be said in the Samkhya-Yoga system the notion of time is beautifully illustrated through Nature, or Prakriti, in its undifferentiated, transcendental state and its differentiated, multiform condition. The reality of time is the reality of the ever self-modifying primary substance.

Histories, Alternative

The literary category of alternative histories is also known as alternate histories, uchronias, allohistories, or counterfactual histories. The last term is often used for serious studies from a historical perspective. Historians run experiments of a sort in complex areas such as economic history by imagining all events that shape an outcome are static except for one change. For example, consider a counterfactual study in which Calvin

Coolidge and a conservatively controlled and business-favoring Congress did not lead the way to a huge difference in wealth between the very rich and the middle class during the 1920s. Economic historians believe this was one major factor that led to overspeculation and then a Depression. In this situation, would the Great Depression have occurred, and if it did not, what major changes would this cause? Would Roosevelt have been elected in 1932?

Besides historical counterfactuals, a good deal of alternative history falls into the fiction genre, and in particular, science fiction. These stories begin with the premise "What If" some single significant event in history either did not happen or happened differently and then go on to explore possible developments. This genre is found in many different languages besides English.

Examples of alternative history appeared in Western literature as early as 1836 with the publication of Louis-Napoléon Geoffroy-Chateau's *Napoléon et la conquête du monde, 1812–1832, Histoire de la monarchie universelle.* This novel tells the story of Napoleon crushing all his enemies and ending as emperor of the whole world. Far earlier in time, Herodotus, in the 5th century BCE, looked at the consequences had the Persians defeated the Greeks at the Battle of Marathon in 490 BCE. Livy's *Ab Urbe Condita* (history of Rome, c. 29 BCE) is considered to have some alternative history aspects.

There were sporadic additional writings now considered to be alternative history during the 19th and early 20th centuries. Examples include a story by Edward Everett Hale in the March 1881 *Harpers* titled "Hands Off." This tale imagined Joseph was not sold into slavery in Egypt, leading to an eventual conquest of the Mediterranean by the Phoenicians.

In 1899, Edmund Lawrence published *It May Happen Yet: A Tale of Bonaparte's Invasion of England.* H. G. Wells's *A Modern Utopia* (1905) falls into one of the subgenres of alternative history, the parallel or alternative Earth plot. In this work, the point of divergence from actual history is the complete skipping of the Dark Ages. In 1926 Charles Petrie published "If: A Jacobite Fantasy," in the *Weekly Westminster,* exploring the idea the Hanoverians fled from Bonnie Prince Charlie in 1745 and the Stuarts were restored to the throne.

More stories and books appeared during the 1920s and mid-1930s. In December 1939, a short story by L. Sprague de Camp titled "Lest Darkness Fall" appeared in the magazine *Unknown.* This story, later published as a novel, is generally credited with the beginning of alternative history as a distinct part of science fiction. "Lest Darkness Fall" involves an archaeologist, Martin Padway, who, while visiting the Pantheon in Rome in 1938, is suddenly transported to the 6th century BCE. There Padway recreates some 20th-century inventions and eventually succeeds in averting the Dark Ages. Although the plot is similar to Mark Twain's *A Connecticut Yankee in King Arthur's Court* (1889), what distinguishes the two is Twain's focus on social inequities and de Camp's exacting historical accuracy in his details. An alternate candidate for this honor is the 1934 short story "Sidewise in Time" by Murray Leinster. However, Harry Turtledove, who has written a number of alternative history novels, as well as some other authors, credits de Camp with getting him interested in this genre.

In the past 20 years there has been a dramatic upsurge in alternative history, not only in novels and short stories but also in all forms of entertainment media. A brief list would include *Timestalkers* (1987), *Sliding Doors* (1998), the *Quantum Leap* television series (1989–1993), *Time Cop* (1994), and *Fatherland* (1994).

An idea that is at the heart of much of alternative history is the "butterfly effect." This is a concept connected with chaos theory and was described by Edmund Lorenz in a 1972 talk titled "Predictability: Does the Flap of a Butterfly's Wings in Brazil Set Off a Tornado in Texas?" A traveler into the past may alter one tiny thing, perhaps just by his or presence alone, which leads to significant changes in the future. This was the basis of one of the most popular classics of the genre, Jack Finney's *Time and Again* (1970), in which a present-day New Yorker joins a secret government project and travels back to 1880s New York. By preventing one chance meeting between two people in the past, the entire project in the future never happens.

One of the largest publishing areas of alternative history is Nazism, the Third Reich, and the Second World War. Gathering interest since the 1970s, this subarea has sparked more novels, short stories, films, television shows, plays, and even comic books than any other topic in alternative history. There have been at least 50 novels written with plots ranging from the Nazis winning World War II to something happening to prevent Hitler from ever coming to power. One of the best known is Philip K. Dick's *The Man in the High Castle* (1962) in which the Axis powers won World War II. More recently, Philip Roth's novel *The Plot Against America* (2004) is based on the famous aviator and America-first isolationist Charles Lindbergh defeating Franklin D. Roosevelt in the 1940 election, leading to America's neutrality in the war against Hitler's Nazi Germany.

The increasing popularity of alternative history, particularly in the popular culture, may owe something to an increase in imagination on the part of filmmakers, disenchantment with the current social and political events in everyday life, and a wish for alternatives. The late-20th-century proliferation of alternative histories was made possible in part by developments in atomic physics. Quantum mechanics, and in particular the Heisenberg uncertainty principle, contradicts age-old beliefs in absolute determinism—the doctrine that all future developments in the whole universe, from the largest galaxy to the smallest particle, are predetermined. If true, this would mean history could never change.

Present-day physics, however, generally accepts a less deterministic view of the cosmos. In the past half-century or so, as physicists and mathematicians attempt to link classical and quantum physics with approaches such as string theory, the possible existence of parallel universes is being explored. Parallel or alternate universe concepts are explored in a number of science fiction novels that may or may not be linked to alternative histories. For example, novels in which the South won the Civil War may predicate an alternative universe in which this is true. Other alternate universe stories with no historical basis involve simple differences such as Jack Finney's *The Woodrow Wilson Dime,* in which the simple slip between parallel universes of a dime with Wilson's image on it causes the protagonist to move into a significantly different, but in some ways similar life.

History, End of

The end of history usually does not mean the end of time. In fact, it means that history has a definite goal in mind, one it is attempting to attain or one it has already reached. These expectations placed on human development depict an image of a meaningful history and comply, in an academic sense, with the school of thought we attribute to the philosophy of history. Classically speaking, when we view history from a philosophical perspective, we don't perceive things as just singular occurrences. We consider them in their historical development. Who determines the course of history? Where do the laws that advance history actually come from? Can the goal of history be judged as positive or negative? All these questions imply how diverse the range of opinions is in regard to this matter. Yet, at the same time, it is possible to identify some of the criteria that are characteristic of end-time thinking: First, people commonly contemplate the end of history during periods of change, times that give them reason to think about the present and the future, because they are either afraid of the unknown or hoping for better times. Second, a primary prerequisite for believing that history has a certain goal that it is heading toward is based on the conception that occurrences are part of a progressive process. Third, this historical process must, however, be understood as human-made; the goal of history must be attainable within the life of human beings and it should not be reserved only for those of divine stature.

Historical Process

There is a basic difference between the way ancient and modern historians view the idea of progress. In early antiquity, history was generally seen as a decline, as the never-ending distancing from the golden ages of mythic times. So, in that sense, the historical process is firmly in divine hands, if it is of any significance at all: History is initiated by the gods and is therefore principally beyond human influence.

According to ancient thought, time flows constantly, without being directed, in the stream of eternal sameness. Certainly, during the course of antiquity, a cyclical picture of history is developed that has been documented in the cyclical theories dealing with transitional political policies. But change occurs essentially along the known paths of human existence. Compared with the anthropological constants that characterize humankind, social and cultural factors are of no particular significance. This even applies to a thinker like Heraclitus (c. 535–475 BCE), whose philosophy centers around the cosmic idea of becoming and passing away. But this thought has nothing to do with progress; change will not necessarily produce any improvements, so it is nothing to place your hopes on. That is also a reason why there are no relevant drafts of the future from that period of time. History is fundamentally the rendition of stories that illustrate human existence—as exemplified by Thucydides (460–c. 396 BCE) in his study on the Peloponnesian War.

Not until Judaism appears on the scene does a new awareness of time evolve: The belief in a future Messiah becomes a historic expectation that defines life itself. The anticipation of a redeemer gives an extraordinary meaning to the future and a structure to the historical process that has a redeemer as its goal. Consequently it is possible to imagine an end of history, even though this development is not historically manmade. Christianity's development is similar: Although world history is divided into a time before and a time after the birth of Christ, historical appreciation remains focused on the Second Coming. Particularly in times of crisis, the promise of redemption has rekindled the specter of doomsday and transformed the fear of Judgment Day into the hope that all misery will come to an end. So it's no wonder that throughout history believers have tried to accelerate salvific history. A vivid illustration of that is offered in the so-called Paupers' Crusade of 1096. But the popular doomsday calculations can also be seen in that connection, because they include the wish to make the Redeemer's Second Coming predictable. The Catholic Church has always eyed these number games with suspicion, in part because they spark a discussion about the expiration date of their own reign. Augustine (354–430) clearly rejected doomsday calculations: First, this knowledge is reserved for God. Second, however, there could not be a qualitative improvement of humanity, historically speaking, because, according to Augustine, Original Sin is the reason why humankind is never purely good or bad; it will always remain in that tense relationship where it depends on redemption. In a similar way, Martin Luther also rejected the thought of humankind actively promoting the Second Coming.

Nevertheless, this belief still finds support within the Christian community, and, in the course of time, it has been partly responsible for the evolution of two complementary structures: While the wish continues to grow that Christ's Second Coming should be "prepared" within the worldly community, the meaning of Original Sin has been losing its significance. The transition is recognizable, for example, in Joachim von Fiore (1130–1202): Joachim differentiates among three realms, those of the Father, the Son and the Holy Ghost, and accordingly teaches that the third realm is immanent, born from the simple strength of monastic contemplation without divine assistance. These teachings are an early example of the budding secularization of doomsday expectations that gained further momentum during the Renaissance. During this era, the vision of history changes drastically. History no longer serves as a voice of divine revelation. It takes on its own significance: History becomes a forum of humankind's ascent to its own Creator who endows it with his divine image, thus distinguishing humankind and setting it apart. With humankind's increasing (self-)confidence, which also includes a worldly portion of truth and goodness, it develops a willingness to accept evil as a worldly matter for religious reasons, as did Thomas Müntzer (1486/1490–1525). According to Müntzer, the teachings of original sin begin to fade, and the battle between good and evil that was carried out within humanity itself now becomes a battle of good people versus evil people. That is why Müntzer felt obligated to "purge" the Christian community of the false-believers, in order to herald the Kingdom of God.

Meaningful History

Human beings make history. This understanding of history becomes more and more widely accepted until it is universally acknowledged in the French Revolution. During the revolution, history itself becomes the subject. Time draws a line. It becomes the modern age, leaving the ancient regime behind. Contrary to prior experience, traditions no longer have any intrinsic value of their own. They are outdated; the past is actually seen as the past. People are no longer embedded in existing structures. There are now unforeseen possibilities, and the future appears to be open and manageable. In antiquity it was the anthropological constants that determined thinking; now it is social circumstances. Conditions that are hostile to freedom and contradict the ideals of equality are removed by means of revolution and reform. The end of history now refers to a situation where human capabilities are optimally developed and established by people themselves.

For Immanuel Kant (1724–1804) this is a regulative idea that shows lawmaking reformers which way to go; for other representatives of German Idealism, for example Johann Gottlieb Fichte (1762–1814), this demand sounds "more final." But it was especially the early socialist currents of the 18th and early 19th centuries that portrayed a happy end of history with their utopias; among them were names like Charles Fourier (1772–1837), Henri de Saint-Simon (1760–1825), and Wilhelm Weitling (1808–1871). They all shared a belief in the power of the Enlightenment and the goal of making the system of political dominance and economic exploitation superfluous.

August Comte (1798–1857), one of the founding fathers of French sociology, developed one of the most mature programs of this nature: Like many of his socialist comrades-in-arms, Comte was inspired by the innovative capabilities of science and technology and regarded the social sciences as the foundation for a controlled "reconstruction" of society, quite similar to the way the natural sciences controlled nature. To him, progress is no longer a question of faith or hope but one of positive knowledge, "positive" in the sense of real, useful, and precise knowledge.

Comte based his Law of Three Stages on this belief, claiming that knowledge first passes through a theologically fictional stage, then a metaphysically abstract stage before finally reaching a scientifically positive state formed by a spirit of order and progress. As soon as it is possible to subject the social changes to an intellectual authority, consisting of the most capable scientists, happiness on Earth will be assured. An earthly paradise under the political leadership of the intellectual elite sounds like a "positivistic" Plato—and it is no wonder that Karl Marx (1819–1883) rejected this and other programs as idealistic.

According to Marx, it was naïve to believe that the effective powers of capitalism could be replaced by humanistic reason. Marx was convinced that the only way bourgeois society could be overcome was through its own contradictions. For instance, Marx's well-known quote about capitalism digging its own grave says that the bourgeois relations of production themselves will reproduce the class struggle between capital and labor without initializing the instruments of compensation. Therefore, this conflict, according to Marx's analysis, has an antagonistic structure: More and more workers will be enslaved by economic necessity and forced to carry their own skin to market, while more and more capital will be amassed in the hands of very few who will become richer and richer. It is this law of development for history itself that determines the course of affairs, no matter what the players want to do or should do. So the end of a certain history is predetermined. In this case, it is the history of bourgeois society.

End of Modern Society?

As is commonly known, bourgeois society not only failed to come to an end, it also successfully outlived its rival political systems in the context of the East–West conflict. The collapse of communist rule in the Soviet Union in 1989/1990 enabled the spread of liberalism in Central and Eastern Europe and inspired the hope of a "new world order," supported by a consensus of the community of states and based on human rights and human dignity. This optimism is reflected in the analysis published by American political scientist Francis Fukuyama titled *End of History,* first as an essay in 1989 where it was tagged with a question mark, and then as a book in 1992. Fukuyama claims that political reason has reached its goal, because liberal democracy has succeeded in becoming the adequate form of government for people in comparison with other political systems. Significant occurrences should not be excluded, but they will not alter the basic situation that—seen from a universally historical perspective—political development must result in a marriage between democracy and the market economy. There are no other alternatives.

Fukuyama bases his historical considerations on an interpretation of G. W. F. Hegel by Alexandre Kojève (1902–1968). In Kojève's version of Hegel's *Phenomenology of Spirit,* the end of history is reached when the contradictions that had previously existed in the various struggles for recognition are resolved and shared by everyone. Contrary to Marx, Kojève specifically assigns capitalism the competence not only to spread affluence and global standards of values and rights but also to balance the inequalities of the market and to redistribute prosperity. He envisions a state of universal freedom and the successful emancipation from all pressures for modern society.

Kojève's interpretation, which is especially influential in French philosophy, should not be understood as a true-to-the-original reconstruction of Hegel's philosophy. Hegel (1770–1831) himself does not assume that the dialectical logic of the struggle for recognition will be overcome. The state may restrain the struggle between individuals, but the intergovernmental world remains in its natural state and thus in the paradigm of the struggles for recognition. It has always been this point of view that others have used to accuse Hegel of having glorified the nation-state. For Hegel, however, it is more a matter of the plurality of concrete life forms. The Age of Enlightenment's universal demand should not seduce us into overlooking the fact that particular "national characters" have lives of their own regarding specific political communities; in Hegel's opinion, that would be an example of apolitical thinking denying itself the insight into the bourgeois era's cultural bondage. The tendencies of bourgeois society to expand into a world community is based on the success of the economy's division of labor. But it is Hegel's conviction that "no state can be established" on the interplay of diverse egoistic interests, calculated economic decision making, and formal lawmaking alone.

From the perspective of Hegel's philosophy of freedom, there is no end in sight for history, either. In Hegel's opinion, freedom and consciousness have a dialectic relationship: History advances in an awareness of freedom when its consciousness becomes conscious of itself and propagates itself as self-consciousness, as in the case of the French Revolution, which marked a decisive breakthrough toward general and political freedom. Yet this new understanding of freedom also introduces new demands that Hegel discusses in the context of the Jacobin terror. In view of the demands of the modern globalized world, Hegel would hardly speak of the end of history. Instead he would speak of the need to understand the ambivalences of freedom. This not only requires that the processes that brought about a lasting impulse for integration following the end of the East–West conflict in Europe are taken into consideration. It also requires that the "opposing movements" of regionalizing systems of order are understood, movements that stir up new conflicts and transform old systems. So it remains to be seen whether the effective cultural diversity, for example, between Islam and the West, will be consolidated in a new systematic rivalry, a "Clash of Civilization" (S. Huntington). And the future of liberal democracy is just as uncertain, considering that the majority of nations will hardly accept it as the universal and ultimate goal of history.

This "realistic" point of view of an uncertain future has also led, among other things, to a greater theoretical humility within political philosophy and the theories of international relations. On the one hand, it has promoted historico-philosophic reflections on end time that are connected to postmodern and post historical concepts. Even Kojève is ambivalent about his envisioned final stage of history: In the general state of happiness, man's "negativity" fades, Kojève claims, and with it his will to overcome himself, his ability to transcend his own nature. This view also absorbs Friedrich Nietzsche's (1844–1900) thoughts on the "last man," who tries to numb the pointlessness of his existence by satisfying his "little desires." One of Nietzsche's central thoughts consists in enlightening the world about the end of all illusions. Human reason set forth to retrace Christianity's promise of truth and morality; but, according to Nietzsche, it found—in the truest sense of the word—nothing. Consequently, man's own self-enlightenment had to end in the "death of God," making man responsible for the meaning of his own life. In Nietzsche's opinion, it is a task only the strongest individuals are able to cope with.

Postmodernism celebrates this disillusionment—in the words of Jean-François Lyotard (1924–1998)—as the "end of the great tales." It opens the world to a pluralistic diversity of views and attitudes that also allow criticism of the outdated ideas of a self-dependent subject. According to the views of postmodern theorists, it doesn't have as much to do with the end of history as with the end of the totality of every historical interpretation based upon reason. They don't see the open future as uncertain. They understand it as a form of liberation, opening the world to the chance of new ideas. Specifically, this belief in the power of innovation, particularly in the areas of the arts and culture, is branded by the post-histoire representatives as an illusion. Not diversity but simplicity characterizes the personality of the modern age. Yet this hectic business, as Arnold Gehlen (1904–1976) claimed, cannot deceive us from seeing that it is essentially just cultural redundancy. Only remakes and recycling, but no real progress anymore, neither in the arts nor in other social areas. The post-histoire view says that history has come to its end, because society has lost the strength to set new goals.

By reviewing the history of philosophy (of history) and considering the various schools of thought, it seems that any reflections on the end of history are a question of mood that can be compared to a theory of colors: ranging from hopeless black to gloomy gray to a happy colorfulness and a confident rosy-ness. So the course of history is, to quite a relevant extent, a question of what people themselves are willing to risk.

Hitler, Adolf (1889–1945)

German dictator Adolf Hitler (born Adolf Schicklgruber) was the leader of the Nazi party and Führer of the Third Reich of Germany from 1934 to 1945. He and his National Socialist movement were one of several nationalistic and racist mass movements that arose from the political and economic problems that followed World War I. Hitler and his followers were responsible for many of the events that led to World War II, most of which shaped the latter 20th century. His promotion of racial supremacist doctrines and anti-Semitism culminated in the Holocaust, the systematic murder of more than 6 million Jewish civilians. Consequently, Hitler left a tragic and indelible mark on recent human history.

With the outbreak of war in 1914, Hitler volunteered for action in the German army. He fought on Germany's Western front for 4 years. Injured and gassed, Hitler won the highly respected Iron Cross. After the German defeat, he became convinced that his country was not defeated on the battlefield but was stabbed in the back by traitors, Jews, and Marxists who sabotaged Germany with the Treaty of Versailles, by which the victorious Allied powers inflicted humiliation and ruinous reparation payments on a defeated nation.

After the war, Hitler attended a German Workers' Party meeting, joined, and became one of the party's best speakers. The party was one of many political groups formed after Germany's defeat that called for national unity and promoted anti-Semitism. These militant and nationalistic parties were similar to those fascist parties in Italy and Spain that were radical, anti-liberal, anti-Marxist, and authoritarian. When Hitler became leader of the party in 1921, it was renamed the National Socialist German Workers' Party (the official name of the Nazi party).

Runaway inflation and the French occupation of the Ruhr Valley contributed to the growth of the Nazi party in Germany. Hitler hoped to end the Ruhr occupation by staging the "Beer Hall" Putsch of November 8–9, 1923, to march against the government in Berlin. The attempt failed and Hitler was tried for treason and sentenced to prison. During his imprisonment, he dictated *Mein Kampf* (1925), an autobiographical account of his life and political philosophy in which he described Germany's need to re-arm, become self-sufficient, suppress Marxism, and rid itself of the Jewish minority.

The conditions of the Great Depression were especially severe in Germany during the postwar period of the Weimar Republic; widespread poverty and public demoralization aided the growth of the Nazi party to the point that, in January 1933, President Hindenburg called Hitler to be chancellor of a coalition government. Hitler consolidated his power by persuading the government to suspend the constitution and to grant him emergency powers. At the death of President Hindenburg in August 1934, Hitler merged the offices of Chancellor and President to become the single leader of both the Nazi party and the Third Reich. Consequently, Germany became a one-party state as other political parties were banned and the unions were destroyed.

Hitler began massive rearmament and a building program to ready Germany for war. This stimulated the German economy, making him a popular leader. He included a propaganda campaign promoting German nationalism, stressing themes from the 19th century that focused on military losses to the French and called for a return to the glories of the Prussian state.

His power secured in Germany, Hitler took advantage of the appeasement policies of the French and English governments. Germany walked out of the Geneva Disarmament Conference and withdrew from the League of Nations. Hitler militarized the Rhineland in 1936, contrary to the disarmament clauses of the Treaty of Versailles. Next, Austria was annexed to Germany in the 1938 Anschluss, followed by the annexation of the Sudetenland of Czechoslovakia with the 1938 Munich Agreement. These annexations led Hitler to be named *Time* magazine's Man of the Year.

On September 1, 1939, Hitler's armies invaded Poland. Alarmed at Germany's full occupation of Czechoslovakia, a violation of the Munich Agreement, France and Great Britain honored their agreement to keep Poland independent and declared war against Germany. By 1940, Hitler had gained control of Norway and Denmark. Next, he focused on France, Holland, and Belgium. Only Great Britain, in the Battle of Britain, repelled German advances.

Hitler invaded Russia on June 22, 1941. The Soviets held the Germans at Stalingrad in 1943. After the United States declared war on Germany and the Allied efforts intensified, the German army lost momentum and the tide of war began to turn against Germany. Hitler gradually withdrew from public view and ignored advice from his military generals. He also intensified his execution of Jewish people in conquered territories; Jewish ghettos and villages were emptied and survivors sent to concentration camps for extermination. But a series of Allied victories continued to drive back the German armies, and an invasion of Germany became inevitable. As Soviet troops converged on Berlin, Hitler escaped to an underground bunker and committed suicide on April 30, 1945. Germany surrendered in May.

Hitler's dream of a greater Germany existed a little over 12 years and caused the death of approximately 50 million people globally. It took a coalition of world powers to defeat the German military in a war that lasted nearly 6 years. To prevent future conflicts, the Allies formed the United Nations, whose first act was to ratify the creation of the new Jewish state of Israel, in response to the Holocaust.

The legacy of Hitler's actions continued for nearly half a century as a weakened Europe became a battlefront in the Cold War between the Soviet Union and the United States. Germany itself was divided in half; though defeated, both sides of Germany were coveted by the superpowers for military support. To some degree it was the political instability in postwar nations that allowed anticolonial movements in Asia and Africa to form independent states, and the resistance to these movements led in turn to conflicts such as the Vietnam War. Former German territories in central Europe, liberated by the Soviets at the end of the war, had Communist regimes installed. The Soviet occupation plus the memory of the failed Munich Agreement made political appeasement unattractive as a foreign policy; it helped to establish the policy of communist containment by the United States that lasted until the reunification of Germany in 1990 and the dissolution of the Soviet Union in 1991.

Homer

Homer is the conventional name of the supposed unitary author of the famous Greek epics *Iliad* and *Odyssey* that were composed shortly after written language came into use again in the first half of the 8th century BCE. The *Iliad* dates to the second half of the 8th century BCE and is the oldest written literature in the West that has come down to us. The *Odyssey* seems to have been written slightly later, possibly by a different author. Marking the end of a long oral tradition, both poems show characteristics of oral improvisation, as in the use of formulaic phrases typical of extempore epic traditions, including the repetition of entire verses. At the same time the poet is held in highest esteem because of his ingenious and creative composition.

There is not a single contemporary document about Homer's life, person, and time, since the first sources from the 7th and 6th centuries mentioning him do not seem to know an official calendar and refer to him merely as a poet of past times. The question of authorship, date, and transmission, the so-called Homeric question, was discussed by modern scholars for about 200 years. Whereas F. A. Wolf (1795) and his school of "Analysis" tried to identify different poets emphasizing the inconsistencies in both epics, the "Unitarians" put stress on their artistic unity. Since the 20th century, the mechanisms and effects of oral transmission, as well as the poetic and aesthetic quality of the poems, have been the focuses of attention.

In both the *Iliad* and the *Odyssey* time is referred to in a highly elaborate way. Times of the year and the day are expressed by verbal pictures; for example, the morning is frequently described by the appearance of the rosy-fingered goddess Dawn (Eos) and by a variety of terms, such as the frequent use of *etos* for a certain year and *eniautos* for the general course of a year with its regular natural phenomena that recur every 12 months. The meaning of some of these terms is still under discussion: looking *prosso kai opisso* is usually translated as looking "forward and backward," that is, "into the future and into the past," although it seems to mean looking "forward and beyond" at times. In this latter case, one anticipates the near future and the more distant future that hides behind the immediate future.

Modern scholarship has proved wrong H. Fränkel's theory of Homer's indifference toward time and Th. Zielinski's opinion that Homer was not fully able to describe parallel plots. Scholars have underlined the difference between the time of narrating and the narrated time (the described actions do not happen as fast or as slowly as the narration goes on) as well as the fine technique of looking back and forward that creates a complex view of time instead of a simple chronological account of the events. Thus both poems consist of a selection of scenes essential for the plot, necessarily focusing on certain periods of time within the set time span. For instance, the plot of the *Iliad,* whose theme is the anger of Achilles, extends over 51 days within the 10th year of war between the Achaeans and Trojans. It does not include the end of the war, because Achilles' anger had ended before the conquest of Troy. The events of only 15 days and 5 nights are described in detail, while those of the remaining days are merely mentioned (e.g., 9 days of plague, absence of the gods for 11 days, Achilles' ill-treatment of the corpse of Hector for 11 days). Aristotle praised Homer for concentrating on the plot in a way that would befit tragic writers, by leaving out all scenes that would need to be included from a historical point of view but that are not an essential part of the plot, which evolves from the characters of the protagonists and their interaction with the gods according to Zeus' plan.

Hominid–Pongid Split

During the past 2 centuries, curious scientists have laid the foundation for answering the question of human origins using advances in technology. Fossil evidence and genetic studies have made this quest possible. Patient accumulation of evidence has led to gradual acceptance by the general public of the conclusion that our species has evolved, during 5 million years, from an ancestor in common with the four great apes in the remote past.

Aristotle, considered the founder of biology, was the first to effectively place animals in a specific order of taxonomy. By organizing species into common groups, he established a foundation for understanding the similarities among life forms on this planet. Even so, he taught the eternal fixity of all species.

Linnaeus, the father of modern taxonomy, took the science of classification to the next level. A species is seen as a group of individuals that share enough biological similarities that they can interbreed with one another successfully. The primate order, which was formed about 70 million years ago, is divided into two suborders: Prosimii and Anthropoidea. Being hominoids, humans and pongids (apes) are placed into the same taxonomic family due to their biological similarities.

Linnaeus's writings were available in the century before Darwin's *On the Origin of Species* (1859). If it were not for Linnaeus's work in biological classification, it would not been possible to speculate on how some species die off and new species are formed. This was later explained by Darwin with his theory of evolution. Darwin realized that species are not in a static state, since everything is in a dynamic process that results in constant change. With the uses of relative dating techniques, Darwin came to the conclusion that fossils in rock strata demonstrate a continuous organic evolution that led to a species' survival or extinction.

Advances in radiometric techniques have allowed scientists to date fossil evidence more accurately. The modern technology of chronometric dating, through the use of radioactive decay, has greatly strengthened the hypothesis that our species has evolved from a common ancestor close to the four living great apes (orangutans, gorillas, chimpanzees, and bonobos). Darwin argued that our evolution took place in Africa. Scientists realized that, to find the truth about our evolutionary past, they had to gather empirical evidence to solve the mysteries of our origin and history. For more than a century, they have searched for the so-called missing link between the great apes and humans.

The first major discovery that established our descent from a common ancestor with the apes was made in Africa, and known as the "Zinj" skull. This unearthing in 1959 by Mary D. Leakey shed light on the hypothesis that our species is more similar to the great apes than had been thought. Several decades ago, anthropologists thought that the split between fossil hominids and fossil apes had occurred during the Miocene epoch, about 12 million years ago. However, more recent hominid species found in southeast Africa are also pongid-like. This evidence from the Pliocene, about 5 to 7 million years ago, determines that our split from the pongids was more recent than had been thought.

During the Miocene, hominoids emerged in many varieties. Before the end of the following Pliocene epoch around 3 million years ago (mya), the environment had changed; the tropical jungles of Africa had become scattered woodlands and open savannas. This change directly resulted in the split between early hominid-like hominoids and pongid-like hominoids. Based on fossil evidence, this split from Pliocene pongid-like hominoids happened roughly 6 mya. The species that were able to adapt to living a terrestrial life survived to form our more recent ancestors. Bipedality is the true separation between the fossil apes and more human-like forms. Many other specializations like tool-making, articulate speech, and a far more complex brain where all later developments during the past 3 million years.

An early ancestor that was successful in this transition from quadrapedal movement to bipedality is known as *Australopithecus afarensis;* the features of *afarensis* are from the neck up chimpanzee-like and from the waist down human-like. The discovery of *afarensis* was only the beginning; scientists are still trying to uncover more clues from our distant past. Interpreting the evidence in order to determine the evolutionary advantage for becoming bipedal continues.

Owen C. Lovejoy, an anthropologist and an expert in anatomy, was the person whom Donald C. Johanson trusted in studying his discoveries at Hadar. Lovejoy has been an influential contributor to the understanding of our past; he believes that our evolution was based on a social advantage that leads to our survival. Hominids created an evolved breeding strategy that enabled humans to raise fewer children, but also allowed them to focus on the success of a limited number of offspring. Lovejoy believes that hominids' opportunity for success revolved around living in large monogamous groups. This is supported by the secondary characteristics that have formed to create the modern human; these phenotypes control the amount of competition between males. In the animal kingdom, an obvious way for species to determine if a female is in heat is to observe the inflammation of sex organs and the growth of breasts. These characteristics are clear signs that lead males to fighting, which would lead to the disbanding of groups. In hominids, it is difficult to make this distinction when a woman is not pregnant. Many criticize this theory of a monogamous relationship, because it goes against Darwin's evolutionary logic. Without the most dominant males passing on their genes to multiple partners, how would hominids survive? Lovejoy answers this argument with the theory that by males appealing to a singular mate, using their time during the day to gather food for not just themselves but also their partner, they allow the females to spend all their time raising the offspring. This allows for a successful passing on of their genes. Another major distinction between the pongids and hominids is that we evolved from being simply insectivores or vegetarians to being primarily omnivores; this allowed for a broad diet that provided a better opportunity for survival in an environment where grasslands where slowly replacing forests in Africa. Through cooperation, *afarensis, Homo habilis, and Homo erectus* allowed humans the opportunity to exist. The creation of a more complex brain came later in the development of *Homo sapiens sapiens*.

From close genetic similarities and observations of human and pongid social behavior, many scientists now recognize that, as mentioned earlier, the split between the hominids and pongids did not occur in the Miocene epoch, but more recently in the Pliocene. In recent decades, biologists have come to the conclusion that our species is more similar to the great apes than had been imagined even by Darwin.

Hourglass

The hourglass, also known as the sandglass, is a timekeeping instrument that has been used for centuries. The sandglass is constructed using two conic reservoirs that are joined at their apexes by a small hole. One reservoir is filled with a finite volume of sand that flows into the bottom reservoir over a set duration of time. When the sand has run completely from the top reservoir through the small opening, the previously determined time period can be recorded and the timepiece inverted to begin running again. The hourglass has been made in various time denominations ranging from 30 seconds to longer than an hour.

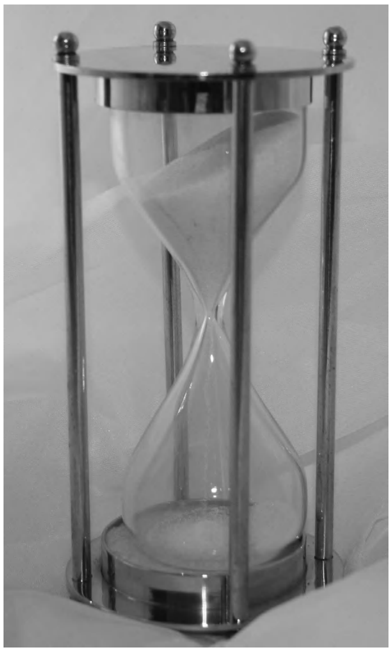
History

The actual date of the hourglass's emergence cannot be definitely placed. There are, however, many theories as to when the hourglass emerged as a common timekeeping instrument. The most significant clues to the invention of the hourglass deal with the dates of portrayals and the emergence of the technology needed to create the glass to make the reservoirs. No record exists of the sandglass's original form, so researchers have to work with the modern hourglass shape. Items were made from glass as far back as 2500 BCE, but the art of glass-blowing was not perfected until around 70 BCE.

The earliest definite depiction of an hourglass dates to between 1337 and 1339 CE. This depiction can be found in an Italian fresco on the walls of Palazzo Pubblico in Siena and was painted by Ambrogio Lorenzetti. Another early depiction of an hourglass can be found at the Mattei Palace in Rome. The palace contains a Greek bas-relief depicting Morpheus, the god of time, holding an hourglass. German artist Albrecht Dürer (1471–1528) profiles the hourglass prominently in many of his artistic works. The sandglass holds a prominent place in all three of his most famous copper engravings. *Knight, Death, and the Devil* (1513), *St. Jerome in His Study* (1514), and *Melancholia I* (1514) depict the hourglass just to the left of the central character. The first textual reference can be found in the Receipt of Thomas de Statesham, which dates to around 1345. This receipt references Thomas's acquisition of 12 hourglasses ("*pro xii orologiis vitreis*") in Flanders. The second textual reference dates to slightly after this, in 1380, and can be found in a furniture inventory of King Charles V of France: "*ung grant orloge de mer, de deux, grans fiolles plains de sablon en ung grant estuy de boys garny d'archal*" (a large sea clock with two large phials filled with sand, in a large wooden brass-bound case). The hourglass also finds reference in classical literature, specifically in the works of William Shakespeare. Specifically, Henry V (Act 1 Scene I) refers to an hourglass in the opening Chorus.

One theory credits the invention of the hourglass to an 8th-century monk of Chartres named Luitprand, but most historians believe that if there is any truth to this theory it would find credence as a reinvention or an improvement on the ancient sandglass after the Dark Ages. Many historians believe the hourglass came into use about the same time as, or slightly after, the clepsydra (water clock). Since both timekeepers use the same basic principle, emergence during the same approximate time period could be likely. For a long time no distinctions were made between the two, and they were simply called *horlogues,* leaving only context to determine which of the two was being described. This theory places the invention of the hourglass at around the 3rd century BCE in the Egyptian city of Alexandria. The sand for the hourglass would have been more accessible in regions with drier climates. In countries such as Egypt, water would have been scarce and not a resource that could be needlessly wasted. The more probable date of emergence coincides with the inception of sea travel, as the technology would aid in nautical navigation.

The hourglass has many advantages over the clepsydra. Sand, unlike water, flows at a consistent pace when pressure is applied from above. For this reason, sandglasses kept a more consistent and steady time. Moreover, unlike water, the sand would not freeze or evaporate, so no replacement filler was ever needed. Most high-quality sandglasses did not actually use sand, however, but finely crushed eggshells. The eggshells provided a smoother flow than sand and therefore provided a more accurate method of keeping time.



Several factors contribute to an hourglass's ability to accurately measure time. The type and quality of sand is important, and it must have a rate of flow that does not fluctuate.
Source: Patricia E. Green/Morguefile.

Ancient Variations

The hourglass has had many different variations since its invention. Although the hourglass and sandglass have become synonymous in modern meaning, ancient variations of the hourglass used different fillers as the timepiece evolved. Some ancient variations used mercury instead of sand. These variations required an extremely fine hole between the reservoirs to keep the mercury from flowing too quickly. Another mercury variation used a small bubble of mercury inside a narrow tube containing air. The resistance from the internal air pressure allowed the mercury to fall slowly through the tube and therefore allowed the measurement of a useful time period.

Since the original form of the hourglass is not known, it would be fair to consider the clepsydra and early sand clock (*clepsammia*) among the very early forms of the hourglass. Both of these early timepieces use a set amount of water or sand, respectively, and measured time by the volume of water and sand in a bottom reservoir, but could not be reset without refilling the top.

Ancient and Modern Uses

The hourglass found use in various places throughout history. The most notable of these is in the field of nautical navigation. In the early era of sea travel, it was crucial for ancient mariners to know the speed of their ship in order to know their location at sea. The hourglass provided a timepiece that would remain stable and reliable even in turbulent weather. Thirty-second sandglasses were used to calculate speed. Tying a rope to a heavy piece of wood and throwing the wood overboard behind the ship calculated speed. The wood created resistance with the water and dragged the rope out behind the boat. The rope would have knots tied 47-foot, 4-inch intervals so that each knot that ran through the fingers of the navigator in the 30-second time period indicated one nautical mile in an hour.

Sandglasses were also used as timers for all sorts of activities. They became the first industrial timers for early factories. *Das Feuerwerkpuck* (1450), a German essay on manufacturing, contains an illustration of a stamping mill being timed by an hourglass. Both politicians and clergy also used the sandglass as speech timers. The hourglass was introduced into the church during the 16th century as a tool to restrain preachers from speaking too long. The hourglass also served as a symbol during olden funerals that the sands of life had run out. In today's era, the sandglass has all but disappeared as a timer except for use in kitchens as the common 3-minute-egg timer.

Humanism

While the word *humanism* is recent, the idea of humanism is one of the oldest and most transnational worldviews in human history. Most worldviews are defined in terms of the distinctive beliefs they hold, but the principal feature of humanism is not so much its core articles of belief, but the method by which inquiry into the world is undertaken.

The American philosopher Paul Kurtz provided what is perhaps the simplest understanding of humanism when he defined it in terms of its four constituent features. First and foremost, humanism is a method of inquiry; second, it presents a cosmic worldview; third, it offers a set of ethical recommendations for the individual's life stance; and, fourth, humanism expresses a number of social and political ideals. It is important to note the order in which these characteristics have been listed. Indeed, this order is a result of the seriousness with which humanism takes cosmic and evolutionary time. Number 4 is the least important of them, not because social and political ideals are unimportant, but because the nature and orientation of those ideals have been more susceptible to change over time and between continents. Numbers 2 and 3 are more important because the details of the worldview and the ethical recommendations have greater commonality over time and across cultures.

But the most important single characteristic of humanism is the one that is most impervious to the passage of time. The most constant defining feature of humanism is that it is a method of inquiry. From the Carvakas and Ajivikas in ancient India, from Kongfuzi and Wang Chong in China, from Thales and the Greek thinkers, through the Renaissance to the Enlightenment and on to the 21st century, humanism is best understood as a method of inquiry. The *conclusions* of that inquiry may change between cultures and between centuries, but the *method* of inquiry has remained essentially the same.

Symptomatic of the uniqueness of humanism is that for most of its life it has functioned very well without the word. Humanism as a *concept* has its origins in ancient India, China, and Greece—each one arising independently—but the actual *word* was not coined until 1808, in Germany. To make things more complicated, *humanist* existed as a word long before *humanism,* originating in the Renaissance, although traceable to the Roman word *humanitas*. But as humanism is defined principally by its method rather than by its conclusions, the lack of a word to act as a catch-all for those conclusions is a trivial issue.

Other philosophers, while agreeing that the method of inquiry remains the single paramount feature, have tried to articulate some general idea of what humanist philosophy would actually subscribe to. The best thought-out was by the American philosopher Corliss Lamont (1902–1995). In an influential account of the philosophy of humanism, one that went through several editions, Lamont outlined what he called the 10 central propositions of humanist philosophy.

1. Humanism believes in a naturalistic metaphysics or attitude toward the universe that considers all forms of the supernatural as myth.

2. Humanism believes that humankind is an evolutionary product of the nature of which we are a part; it has no survival after death.
3. Having its ultimate faith in humanity, humanism believes that human beings possess the power of solving their own problems, through reliance primarily upon reason and scientific method applied with courage and vision.
4. Humanism believes that all humans possess genuine freedom of creative choice and action, and are, within certain objective limits, the masters of their own destiny.
5. Humanism believes in grounding all human values in this-earthly experiences and relationships, and it holds as its highest goal this-worldly happiness, freedom, and progress—economic, cultural, and ethical—for all humankind.
6. Humanism believes that the individual attains the good life by harmoniously combining personal satisfactions and continuous self-development with significant work and other activities that contribute to the welfare of the community.
7. Humanism believes in the widest possible development of art and awareness of beauty, including the appreciation of nature's loveliness and splendor, so that the aesthetic experience may become a pervasive reality in the life of man.
8. Humanism believes in a worldwide democracy, peace, and a high standard of living on the foundations of a flourishing world order.
9. Humanism believes in the complete social implementation of reason and scientific method; and thereby in the use of democratic procedures, including full freedom of expression and civil liberties, throughout all areas of economic, political, and cultural life.
10. Humanism, in accordance with scientific method, believes in the unending questioning of basic assumptions and convictions, including its own.

The 10th proposition is significant. As with Kurtz's preference for seeing humanism as a method of inquiry, Lamont is clear that humanism is just as rigorous in questioning its own presuppositions as those of any other system. We may quibble over this or that point in Lamont's list, but the 10th proposition helps ensure the need for ongoing inquiry as the core humanist process.

Another account of humanism, by the philosopher Mario Bunge, seems at first sight to come from a different perspective than that of Kurtz or Lamont, but in the end it is the similarities that are more significant. Bunge speaks of humanism as involving concern for the lot of humanity. This concern he spells out in what he calls the seven theses of humanism, which go in this order:

1. *cosmological thesis:* whatever exists is either natural or manmade;
2. *anthropological thesis:* the common features of humanity are more significant than the differences;
3. *axiological thesis:* there are some basic human values, like well-being, honesty, loyalty, solidarity, fairness, security, peace, and knowledge, and these are worth working, even fighting, for;
4. *epistemological thesis:* it is possible to find out the truth about the world and ourselves with the help of experience, reason, imagination, and criticism;
5. *moral thesis:* we should seek salvation in this life through work and thought;
6. *social thesis:* liberty, equality, solidarity, and expertise in the management of the commonwealth;
7. *political thesis:* while allowing freedom of and from religious worship we should work toward the attainment or maintenance of a secular state.

Bunge is an advocate of what he calls *systemism,* which postulates that every thing and every idea is a system or a component of another system. In this way, the first thesis covers the broadest territory, and provides the foundation for the other theses. Looking at it another way, the theses run from the hard sciences through to the social sciences. Interestingly, in the first thesis, which addresses the individual human being, Bunge says what Kurtz also says, namely, the importance of the method of inquiry. From the point of view of time, the focus of inquiry for this encyclopedia, the crucial point of Bunge's systemism is that it proceeds from sectors in which time operates on a macro scale, to sectors operating on much more limited time scales, well within the human ability to grasp.

Humanism in the Ancient World

Humanism is a collective name that can be given to some of the oldest and most transcultural worldviews on Earth, beginning quite independently in India, China, and Greece. Looking to India first, humanist elements can be found in four of the six classic schools of thought (*darshana*) that make up classical Indian philosophy: the Samkhya, Mimamsa, Yoga, and Vaisesika. They either doubted the existence of any God or gods, or valued the acquisition of knowledge of the world as a worthwhile end in itself, or saw harmonious living within the world as freed from illusion as possible, as a worthwhile goal.

The oldest of the Indian *darshanas* is the Samkhya school, which was mentioned first in the 4th century BCE, although it had probably been flourishing for a century or so by then. The earliest known Samkhya work is the *Samkhya Karika,* written by Iswara Krishna about 200 CE. Samkhya thinking developed an elaborate metaphysics that was, broadly speaking, atheistic, recognizing only two ultimate realities: *purusa* (sentience) and *praktri* (matter). *Praktri* is uncaused, eternal, and in a state of constant evolution. It is composed of three essential substances: essence, energy, and inertia. Cosmic history began with these elements being in total equilibrium. Evolution began with the arrival of *purusa,* and is the principle for which evolution continues. *Purusa* is itself entirely uncreated and is neither God nor some sort of prime mover, although some strands of Samkhya thinking tend to promote *purusa* as a variation of universal spirit. It would be a mistake, however, to equate this notion of a universal spirit with God in the Western sense. What divided Samkhya thinkers was whether the notion of God was capable of any proof, or whether it was a mistaken belief. The Samkhya system advocated liberation from the bondage of *praktri* by knowledge, a liberation best equated with philosophical wisdom.

Standing alongside the classical Indian darshanas was the materialist school of thought known as the Carvakas, traceable to the 6th century BCE. Carvaka philosophy shared with other Indian schools the belief that the universe is interdependent and subject to perpetual evolution. But at that point they parted company, holding instead a range of unorthodox beliefs: that sacred literature should be regarded as false; that there is no deity, immortal soul, or afterlife; that karma is inoperative and illusory and matter is the fundamental element; and that only direct perception, and no religious injunctions, can give us true knowledge. The aim in life is to get the maximum amount of pleasure from it. This had various interpretations, from unalloyed hedonism to an altruistic service for other people on the principle that this will maximize one's own happiness as well as that of others. It will be seen that the humanist variants in Indian thought involved to no small extent a differing view of time, being more linear and embedded in nature.

Other Indian movements of a broadly humanist orientation in India include the Ajivikas and the Sumaniya, about which little is now known. The Ajivikas flourished between the 6th and 3rd centuries BCE, and their influence can be traced for more than 1,500 years. Like some early Jains and Buddhists, the Ajivikas went about naked to indicate their contempt for worldly goods. In the main, they upheld a principle of nonaction, denying that merit accrued from virtuous activity or demerit from wicked activity. Coupled with this was a thoroughgoing determinism and skepticism regarding karma and any sort of afterlife.

Humanist elements can be seen in some elements of contemporary Hinduism. For instance, the Rahda Soami group, which is engaged in building a magnificent temple in Agra, not far from the Taj Mahal, is broadly humanistic in outlook. They disavow caste barriers and undue emphasis on ritual and ceremony, and encourage secular and honest living.

In contrast to India, the humanist strand in China became the principal strand of thought. This is largely, though by no means exclusively, due to the influence of Kongfuzi (551–479 BCE), who is known in West by his Latinized name, Confucius. Chinese humanism is placed squarely in temporal time. Confucius's genius involved transforming the naturalism and humanism latent in Chinese thinking into the strongest forces in Chinese thought down to this day. He said that maintaining a distance from spiritual beings was a sign of wisdom; he expressed no opinion on the fate of souls, and never encouraged prayer.

Confucius realigned the concept of *junzi* (*chun-tzu* in old spelling), which had traditionally meant "son of the ruler" into "superior man," with the effect that nobility was no longer a matter of blood or birth, but of character. This was a very radical departure from the customary Chinese thinking preceding him. Along with this, he radically transformed the notion of *jen* from meaning kindliness to the more general "man of the golden rule," or perfect *junzi. Jen* was expressed in terms of *chung* and *shu,* or conscientiousness and altruism. Confucius spoke of the doctrine of the mean, which essentially meant doing things "just right," which in turn meant doing things in harmony with the Dao.

The clearest articulation of Confucian values was given in *The Great Learning,* the classical work of Confucian ethics. Originally part of a large Confucian work called the *Book of Rites, The Great Learning* was later extracted from it and made a standalone Confucian work. It was probably not written by Confucius himself, but by Zengzi (a disciple) or Zi Si (Confucius's grandson). The reference to great learning is to distinguish it from small learning, which children are in need of. The power of *The Great Learning* is that it encapsulates the Confucian educational, moral, and political program in a simple format. First are the Three Ways, or Three Aims: clear character; loving the people; and abiding in the highest good. These Ways are achieved by the Eight Steps: the investigation of things; extension of knowledge; sincerity of the will; rectification of the mind; cultivation of the personal life; regulation of the family; national order; and world peace.

The Three Ways and the Eight Steps encapsulate the Confucian emphasis upon reforming one's character and building social cohesion and the intimate links between the two notions. Another development of what could be called humanist thinking was developed by Mengzi (371–c. 289 BCE), known in the West as Mencius. The Great Morale (*Han Jan Chih Ch'i*) involved the morale of the individual who identifies with the universe. There are two ways of cultivating the Great Morale: understanding the Dao, or the way of principle that leads to the elevation of mind; and the accumulation of human-heartedness, or the constant doing of what one ought to do because one is a citizen of the universe. Through the constant accumulation of understanding of the Dao and cultivation of human-heartedness, the Great Morale will gradually develop within oneself. Mengzi also believed the Great Morale was achievable by everyone, because we all have the same nature, one that, at heart, is good. It is important to see how both processes begin with the individual, working on the basic premise that one can play no useful role in society if one's own personality and family are in disorder. At no point is there any reference to any supernatural order or command morality. Like the Indian humanist systems, Chinese humanism is located within natural time and subject to natural rhythms. It also has important points in common with Mario Bunge's systemism.

In Greece, humanism can be traced back to the philosophers known as the Presocratics; that is, philosophers active before Socrates. Many historians and philosophers have had reason to admire the general attitude of the Presocratics, even if their actual opinions are of less value than the attitudes that underlie them. Bertrand Russell praised them for not only having an open, scientific attitude of inquiry but for their creativity and imagination. In fact, most of the basic categories of philosophy began with them. The first of them was Thales (c. 624–548 BCE), the man credited as being the father of philosophy. Thales' claim to fame rests on being the first person to try to explain the world not in terms of myths, but by observation of the world as he actually saw it. Where Homer attributed the origin of all things to the God Oceanus, Thales taught that water was the prime element in all things.

One of the core foundational concepts of humanism as articulated in Greece was the notion of *Paideia*. The term comes from classical Greek philosophy and is derived from the Greek word *pais* or *paides,* which, translated literally, means "boy," but in its broader meaning can be defined as "education for responsible citizenship." It was understood by the Greeks that this sort of education was an effective democracy. *Paideia* had four characteristics: it offered a unified and systematic account of human knowledge; it provided a technique of reading and disputation based upon mastery of language and intellectual precision; it worked on the assumption that the human personality can be improved by education; and it valued the qualities of persuasion and leadership as important for the vital task of taking part in public affairs. The ideals of Paideia were given their best voice by Socrates who, during the trial for his life, declared that the unexamined life is not worth living. These ideals were imitated by the Romans, from whose language the Latin word *humanitas* comes.

The humanist tradition of Greek thought received a check in the philosophy of Plato, and never fully recovered. Several Hellenistic movements, in particular Epicureanism and Stoicism, reflected important elements of humanist thought, but all had been effectively countered or crushed by Platonism and then by Christianity.

Renaissance Humanism

The collapse of the Roman Empire was followed by what might still justifiably be called the Dark Ages. In these long centuries of faith and ignorance, the spirit of inquiry was almost lost in the West. It revived only with the Renaissance. In its broader sense, the Renaissance began with the life of Petrarch (1304–1374) and ended with the death by execution of Giordano Bruno for heresy in 1600, with the most productive years of the Renaissance being the century before the sack of Rome in 1527.

Medieval thinking had been dominated by cultural pessimism: weariness with this world, and a suspicion, derived mainly from Saint Augustine, that human affairs are inevitably tainted with corruption and selfishness. Renaissance thinking, by contrast, was positive and optimistic. While Renaissance humanism differed on many points, it was pretty unanimous in its condemnation of the monastic life with all its implications of defeatism and withdrawing from one's civic duties.

Humanist thought in the Renaissance is also responsible for some very basic units of periodization of history as developed in the West. The very notion of "Renaissance" came from the idea that this age was the first to rediscover and fully appreciate the cultural grandeur of the ancient world. What happened in between then and now was slightingly dubbed the Middle Ages—those ages of interest only insofar as they stood between the glories of antiquity and the glories of today. We still speak of the Middle Ages, and they have retained in popular imagination the gloomy picture drawn of them by the Renaissance humanists.

The thinkers of the Renaissance saw themselves as the scourge of medieval dogma and the pioneers of a new cultural and intellectual orientation centering on the majesty of the ancient world. The new style of thinking was stimulated by the rediscovery of ancient thinkers, in particular Lucretius, Cicero, and Plato. The Renaissance humanists were optimistic about the power of culture to effect positive social change. At its least helpful, what can be called Renaissance humanism encouraged too backward-looking a stance. The tremendous enthusiasm for the ancient scholars deteriorated into a conservative climate where simple quotation of an ancient authority was sufficient to bring a dispute to an end. Only after the sack of Rome in 1527 did this optimism decline and a return to contemplation and an escape from the world once more became a discernable trend in Renaissance thought.

Very few Renaissance thinkers were atheists: almost all were theists, the majority of them remained Christians, though of heterodox sympathies. Belief in personal immortality came to be questioned, and the understanding of God changed: God was something that could be understood through our learning. Indeed, learning was a deeply pious activity, in that learning about nature meant, ipso facto, learning about God. The influence of antiquity inevitably meant a renewed interest in the pre-Christian ideas of the ancients. Few people declared an overt preference for the pagan ideas, and a rather sophistical justification for interest in the subject developed. The triumph of Christianity, so this argument went, had expunged the danger in paganism, so there now would be little harm in studying it.

The Renaissance was a period of significant historical and scriptural research. For instance, Lorenzo Valla (1405–1457) was responsible for exposing the fraud known as the Donation of

Constantine, upon which the papal claims to own its large territories in Italy was based. Valla also wrote *Dialogue on Freewill,* a frankly skeptical work that is a very sympathetic account of Epicurus. Valla was influential in teaching people the need to read scriptures with a skeptical frame of mind. This religious scholarship of Renaissance scholars was usually undertaken with a mind to reform religion and purge it of its recent and harmful additions. This drive led directly to developing some of the first ideas since the ancient world of religious toleration. This trend came to an end only when the religious reformer Savonarola was burned at the stake in 1498.

Contemporary Humanism

The humanism of both the ancient world and the Renaissance were stifled by religious reaction. It slowly rose again to the surface in the 18th and 19th centuries for a complex array of reasons. The Renaissance and Reformation had broken forever the monolithic idea of a single Christian belief that covered the known world, excepting only a few heathens around the periphery. The discoveries of other civilizations by European explorers also showed that people could live quite happily without Christianity. This, along with greater knowledge of the civilizations of India and China, from which Europe might learn, had dramatic consequences for the monoculturalism of Christian Europe. The Enlightenment in Europe (roughly, the years between the 1680s and the 1780s) was characterized in part by the taking to heart of this realization.

It was during these changes in perception that the word *humanism* was coined, in 1808. Friedrich Immanuel Niethammer (1766–1848) was a German educational reformer who wanted to develop an educational philosophy avoiding the excesses of the Roman Catholic reactionaries and the radicals of his day, known as the Philanthropinists. Niethammer posited humanism as combining the respect for tradition stressed by the conservatives with the innovative education of the whole child, as advocated by the reformers. Niethammer was a close friend of the philosopher George Wilhelm Friedrich Hegel (1770–1831) and it was from him that subsequent writers, thinkers, and reformers took up the idea of humanism and adapted it to their purposes. By the 1870s humanism was known and used in the English-speaking world. It retained its general use as a catch-all idea for the values of the Renaissance or of the classical world until about the end of the 19th century when the philosopher F. C. S. Schiller (1864–1937) took the word up as the title for his brand of subjectivist pragmatism. From there, American religious progressives took humanism up as the word to denote a brand of nonsupernatural religion as personal commitment in the context of a common humanity. This position came to be known as religious humanism.

It was only after the Second World War that humanism became the most widely used word among secularists, rationalists, and freethinkers. Chief articulators of this kind of secular humanism were Corliss Lamont in the United States, referred to earlier; M. N. Roy (1887–1954) in India; and Hector Hawton (1901–1975) and H. J. Blackham in the United Kingdom. Religious humanists and secular humanists do not differ so much in what they believe. Both groupings are fundamentally naturalistic and reject supernaturalist interpretations of religion. They are also generally opposed to ecclesiastical authority being exercised in society and see science as having constructive contributions to make in science, philosophy, and society. Where they differ is more in their general perceptions of what religion is and what their response to it should be.

Returning to Paul Kurtz's outline of humanism, we can trace the changes in two of the points and the continuities in others. Item 2, the cosmic worldview, has become more modest and less geocentric, as required by developments in astronomy and cosmology. Item 4, the political ideals, has become inclusive of more groups than earlier humanisms would have endorsed. Toleration of slavery in ancient Greece and the widespread misogyny found in Confucianism and Greek thinking no longer play a part in humanist thinking.

In contrast to these changes, item 3, the ethical ideals, has remained fundamentally the same. The values identified by Solon, Pericles, Confucius, the Carvakas, or the Epicureans still resonate today. Enjoyment of the moment, resistance to the transcendental temptation, love of nature, impatience with display, imperviousness to materialism, respect for learning, civic values, and family responsibility; all were recommended by the ancient humanists and all find enthusiastic support among their contemporary successors.

But it is the first item of Kurtz's outline that has remained the most constant. The endorsements of skeptical, open-minded inquiry given by Socrates, Wang Chong, and the Ajivika thinker Upaka find direct parallels in the work of Bertrand Russell, Albert Einstein, and all the other humanist philosophers and scientists who have shaped the modern world. Humanism is first and foremost a method of inquiry, and it is the conclusions of that inquiry that furnish us with our ideas and beliefs. Humanists have always rejected static formulas of thought, or bowing to arguments from authority, or accepting command moralities. In contrast to systems that are founded on acceptance of bodies of thought, humanism assumes that as knowledge comes from humans, it is bound to include some element of error and therefore will be in need of revision as our learning grows. In this way, contemporary humanism can reject the anthropocentric conceit of the Renaissance humanists, the hedonism of the Carvakas, the humorlessness of the Stoics, and still honor their role in the long stream of humanist thought. And as our scientific and philosophic knowledge grows, doubtless some important features of 21st-century humanism will be replaced. But the primacy of humanism as a method of inquiry will remain.

Humanism and Time

We can conclude this general account of humanism by returning to its philosophy of time. Humanist outlooks differ from supernaturalist outlooks in many important ways, and these differences have important implications for their respective beliefs about time. In the centuries before the Copernican revolution, classical Western religions posited a geocentric universe that was both very young and very small and that revolved around one's own religious heartland and was geared to one's own needs. This viewpoint became untenable after the 17th century, along with the conceptions of time that attended it. The outlooks that have developed since then, including the humanist ones, have accepted the need for a cosmic perspective, which involves recognizing the relative unimportance of our galaxy, our planet, our species, and ourselves in the wider scheme of things. Baruch de Spinoza spoke in these terms when he extolled the virtue of *sub specie aeternitatis,* or "under the aspect of eternity." This cosmic perspective has been reiterated from humanist viewpoints by people as diverse as George Santayana, H. G. Wells, Bertrand Russell, Steven Weinberg, and Richard Dawkins. It is also similar to Mencius's idea of the Great Morale, mentioned above.

The next major shift in perception came as a result of the breakthroughs in geology and biology in the 19th century; in particular, Charles Darwin's articulation of natural selection as the means by which evolution takes place. Evolution has demonstrated that human beings must extend their newfound cosmic modesty to the animal kingdom. Ernst Mayr determined four basic beliefs central to theism that were overthrown by evolutionary thinking: belief in a constant world; belief in a created world; belief in a world created by a wise and benign creator; and belief in the unique position of humanity in that creation. Each of these beliefs required a radically different notion of time than is compatible with a scientific account. Once again, this involved a serious recalculation of our understanding of time and the relative position of humanity to time. The ongoing dialogue between evolutionary theory and humanist thinking is testimony to this dynamic relationship.

Finally, the falling away of generally accepted externally imposed goals and purposes in life has stimulated among many humanist thinkers an appreciation of living each moment fully and joyfully. Here some of the more religiously and poetically inclined humanists have helped provide the language necessary to appreciate and savor each moment for the joy it can bring, if only we can look openly at it. This has involved some very creative and significant new understandings of what something like "life eternal" can mean.

Hume, David (1711–1776)

David Hume, a Scottish moral philosopher, historian, and public economist, is considered among history's most important British men of letters. A major representative of British Empiricism, Hume influenced generations of thinkers, in particular Immanuel Kant, John Stuart Mill, Adam Smith, David Ricardo, and Friedrich August von Hayek. His writings on perception, causality, history, time, morality, and economics prepared the ground for many important subsequent philosophical and economic schools, for example, Utilitarianism, Rationalism, and the Austrian liberal economic school of the 20th century.

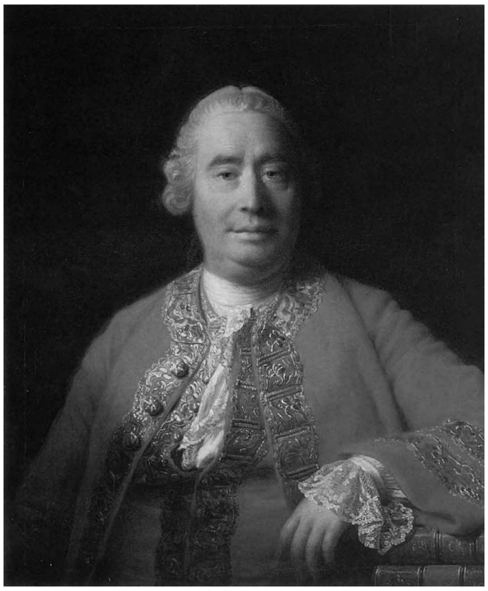
Life and Work

Hume was born into a noble albeit no longer prosperous family in Edinburgh on April 26, 1711. After the death of his father in 1713 he grew up with his two elder siblings under the care of his mother at Ninewells in the Scottish lowlands.

At the young age of 12 he followed his older brother to Edinburgh University. There he first studied mathematics; later on, he studied law but never completed the degree. Soon Hume turned his concentration to the great ancient philosophers, especially Cicero and Seneca. Beyond them he read the major contemporary British writers like Joseph Butler, John Locke, and George Berkeley; he admired them as fathers of moral science that was based on an experimental approach.

In 1734, after several years of intense reading, he felt sick and exhausted. In an effort to recover his health through a change of habits, Hume relocated to Bristol to take up work for a sugar importer. Because this way of life did not suit him at all, he quickly decided to resign and, still in the year 1734, took up his former studies again—but this time in France. Declining to accept gainful employment forced him to live a very modest life for years.

In France he stayed mainly in La Flèche, where roughly a century before Descartes had received his education in the Jesuit College, which still existed in Hume's time. There he read the continental philosophers' works and soon gained back his mental strength. Between 1734 and 1737 Hume composed his initial work, *Treatise of Human Nature*. To finalize the editing and for the sake of managing the book's release he moved to London. The first two volumes—*Of the Understanding* and *Of the Passions* were finally published in 1739.



Portrait of David Hume by Allan Ramsey, 1776. Hume was one of the greatest philosophers in Western history, as well as an accomplished historian and economist.

Eventually the third volume, *Of Morals,* appeared. *The Treatise* included Hume's attempt to introduce a "science of human nature."

But the *Treatise's* tepid reception and miserable sales left Hume disappointed since his ambition from his youngest age onward had been to become a reputable man of letters. Having experienced this frustration, he returned to Ninewells to carry on his studies. In 1741/1742, Hume published his *Essays Moral and Political.* In contrast to the previous work, this one met with wide success.

In search of a stable income and space for further free development, Hume applied in 1745 for a vacant chair of Ethics in Edinburgh. But the "murmur among the zealots" about Hume's alleged skepticism and atheism as voiced in the *Treatise* gave rise to successful opposition against his appointment. For the same reason he failed again 6 years later in Glasgow in his second and final effort to obtain a professorship.

After several short engagements, he followed the call of General James St. Clair—a cousin of his—in 1746 to accompany him as a secretary on a campaign against France, and 2 years later on a diplomatic mission to Vienna and Turin. During his absence his *Philosophical Essays Concerning Human Understanding*—today denoted as his first *Inquiry*—were published; these were succeeded by *Inquiry Concerning the Principles of Morals* and his major work as political economist, *Political Discourses.* The latter attracted international attention.

In 1752 Hume began engagement as Librarian to the Advocates' Faculty in Edinburgh. His primary benefit was being able to pursue his independent studies, allowing him to elaborate and release his six-volume *History of England,* which, again, met with great success. His belief in the necessity of historical classification of current issues and his view on history as immeasurably valuable "collections of experiments" motivated this body of work. In 1757 his *Four Dissertations* were published.

Fortune led him to Paris again, this time (1763) as secretary to the English ambassador. He enjoyed his opportunities to associate with noble Parisian society, with its stimulating and convivial salons. Returning to Britain in the company of Jean-Jacques Rousseau, with whom he shared a brief friendship, Hume soon became undersecretary of state. As a newly prosperous man, he retired to Edinburgh in the late 1760s.

David Hume died in Edinburgh on August 25, 1776, after having spent some years of comfortable life. His most controversial literary work, *Dialogues Concerning Natural Religion,* was published posthumously in 1779.

Moral Philosophy and Method

Hume emphatically distinguished "ought from is"—in today's scientific language to speak from normative versus positive analysis.

Along with Berkeley and Locke, Hume is regarded an important representative of British Empiricism; Hume's theory of knowledge follows the distinction of the perceptions (sensations vs. reflections) of the human mind into impressions and ideas; according to Hume, any idea, however elaborate, is based on a bundle of simple impressions. Hume therefore stated that any theory not empirically based must be rejected categorically. He presented the copy principle (that simple ideas come from simple impressions of the outside world) and thought about the principles of natural connections of ideas in mind—the process of association. These findings had implications for his judgments of the status of the outside world and free will.

Hume bewailed the primacy of passions over sanity in human behavior, causing him to state, "Mankind are so much the same, in all times and places, that history informs us of nothing new or strange. . . ." Some authors took this as an indication of Hume's disregard of time and history; others believed he grasped the understanding of history and reason being central to philosophical advance.

Hume challenged the widespread unconscious supposition of causality between two events closely following another in time. Historically constant conjunction of two events should not be misunderstood as a proof of natural coincidence through causation and must not lead to the firm expectation of conjunct occurrence in the future.

Hume described the custom and habit of induction based on humankind's natural tendency to form expectations of a general circumstance out of single observations of incidents—that is to say, inductive generalizable deductions. He denied that this way of generalizing in order to build expectations for the future was rational, because he did not detect the slightest evidence to confirm such generalization or to believe in even the prospectively constant conjunction as a form of stationary behavior over time. On the contrary, there may occur significant inconsistencies between past and future events. Some traces of parallelism to John Stuart Mill's thought may be discerned here.

Hume doubted the moral rationalists' (in particular Locke's) and the "selfish schools" (e.g., Thomas Hobbes's) behavioral assumptions and thought about the origins of humankind's natural sympathy (benevolence) and morality. Hume tended to be a skeptic, especially in regard to religion.

Political Economy

Beyond his philosophical and historical thoughts, Hume made relevant contributions to the new science of economics. By means of progressive empirical inquiries, he disproved the theories of the strong contemporary school of mercantilists who believed in the achievements of protectionism. Hume spoke in favor of free trade and more dynamic currency regimes and hereby set a cornerstone of classical economics; in this respect he strongly influenced his close friend and later famous economist Adam Smith, as well as constituting a source of Ricardo's monetary theory. Furthermore, he was convinced that in the absence of economic freedom any real political freedom would be unreachable, an idea that later inspired Hayek and others.

Husserl, Edmund (1859–1938)

Edmund Husserl, a German philosopher, was the founder of the phenomenological tradition. He studied mathematics, science, and philosophy in Leipzig, Berlin, and Vienna. In Vienna (1881–1882) he studied with Franz Brentano, who inspired him to establish the phenomenological method, which later became one of the most important philosophical movements in 20th-century continental Europe, influencing among others Martin Heidegger, Jean-Paul Sartre, and Maurice Merleau-Ponty. Husserl taught at Halle, Göttingen, and Freiburg. Before he turned his interest to the development of phenomenology, he worked on the philosophical foundations of mathematics (*Philosophy of Arithmetic,* 1891). In this connection, his discussion with Gottlob Frege, who established analytical philosophy, was important.

Husserl's concept of time was initially inspired by what Brentano had taught in Vienna. Two crucial insights of Brentano became the foundation of Husserl's phenomenology: First, the psychic contents of an experiencing consciousness can be the subject of an unmediated inner perception; and, second, consciousness is always related to something by intention, meaning that there is no consciousness without an intended object. In short, the phenomenal "givenness" of psychic contents and "intentionality" as an irreducible structure of consciousness form the starting points of phenomenology. Time is the system that orders the contents of consciousness first of all, giving rise to before-and-after relations and making the past experiences qua memory accessible to the subject. This means that past experiences become recognizable as one's own experiences; thus, time is a function of self-identity. Until this point, Husserl's notion of time remains quite Kantian.

The Problem of Subjectivity

Specific to Husserl's time theory is the problem of a subjectivity that constitutes time but is also related to an original temporally distributed flow of experiences. That means consciousness constitutes time and is itself temporal. In order to explain this, Husserl introduces the "absolute consciousness," a unifying transcendental function of consciousness that is in itself atemporal. This theoretical construct is contentious not only among his interpreters but also for himself because it cannot become the subject of phenomenological analyses. Phenomenology as Husserl has developed it is a philosophy of description in a strictly scientific sense. The goal of philosophy should be the precise description of how things appear to us. It is not about how things are in themselves, but rather how we apprehend them. Our experience is a source of apodictic truths for Husserl. But the individual contents of consciousness do not belong to these truths; it is the way or the structure in which they are given that can be an apodictic truth. The Kantian distinction between the thing-in-itself and how it appears is to be found in *Logical Investigations* (1900–1901), but in his analyses of time Husserl gave up that sharp distinction. The thing-in-itself is then defined as the identity that can be intuited through manifold apprehensions or perspectives of it. Therefore it no longer belongs to the realm of transcendent things if transcendent is understood as being beyond the reach of our recognition.

The analyses concerning time-consciousness are fundamental to Husserl's phenomenology because time is not an object like other objects; it is rather the way in which objects are given to and apprehended by consciousness. That is why time is so fundamental to phenomenology, and its analysis stretches over the whole period of Husserl's investigations. He focuses on subjective time, the time-consciousness and not on an objective "world-time." In general it can be said that phenomenology is always concerned with how things appear to a consciousness. The question of how things are in themselves misses the point that there is no object without a subject. This does not mean that Husserl is an idealist. He thinks that the attempt to describe something while leaving out the condition that it must be described by someone cannot be a sufficient description and, therefore, cannot be true. Husserl distinguishes two perspectives: the "natural attitude" and the "phenomenological attitude." The former is the perspective we adopt in everyday life, in which we naturally believe in the existence of the world. In the latter, the philosopher suspends all convictions and intentions that belong to the "natural attitude," especially convictions about existence. This suspension is called *phenomenological epoché,* and is gained by a reductive method that leads through different levels back to pure intention. Intention is the way in which a consciousness is directed toward an object. There are many ways in which an object can be given to a consciousness (in perception, imagination, representation, etc.). In order to describe the nature of these modes, Husserl uses variation, the so-called eidetic variation, which is a method of distinguishing between contingent and necessary features of the intention. Intentionality is the subjective structure of consciousness, which apprehends an object. In an analysis, a distinction is made between the *noema* (object of consciousness) and the *noesis* (corresponding mental activity). They can be analyzed separately, but they are not reducible to one another.

Consciousness and Time

The central question concerning time is how temporal objectivity can be constituted by a temporal consciousness. Analogous to this question, the phenomenological analysis splits at first into two subjects: the temporal object (e.g., a melody) and time-consciousness (the succession of now-moments and their becoming more and more past and the anticipation of the impressions yet to come). The constitution of a temporal object, an object that endures identical to itself over time, needs time. That means the time the consciousness takes to constitute a temporal object needs to be just as long as the object endures. While the intuited identity of the object appears as an integral whole, the object is in fact given only in successive perspectives or temporal parts. Husserl takes a melody as an example of how time-consciousness constitutes such a temporal object. He asks why we not only hear the successive tones while listening to a melody, but also grasp them as a whole. His explanation is that time-consciousness is not only consciousness of the present moment ("primal impression"), but rather encompasses moments already past ("retention" or "primary memory") and anticipates others still in the future ("protention"). The now-point is fundamental as a source of the present since consciousness is defined as a continually flowing stream of contents, but the present moment is ideal only in the sense that it has no duration. It is a kind of border between the past and the future. The temporal field, the duration of the present composed of past, primal impression, and anticipation, is necessary for the connection of the different tones and the recognition of the melody. The succession of primal impressions causes the backward-shift of the former primal impressions, and, therefore, the temporal field of what is recognized as present is continually changing. The function of "secondary memory," which is distinguished from retention, is to keep all continually changing apprehensions in mind, so that the whole continuum of the temporal phases of the melody can be apprehended as a whole. The content of this secondary memory is not present, but remembered or, as Husserl puts it in *On the Phenomenology of the Consciousness of Internal Time* (1893–1917), the "re-presented present." This kind of memory is also distinguished from what is commonly called memory, the reproduction of an impression in the mind. Time-consciousness is clearly distinguished from and not reducible to any other kind of mediated consciousness like imagination, sign-reading, or consciousness of pictorial images; it is a consciousness sui generis since it apprehends something as present that is not present as a whole, but that is held in consciousness as if it were present as a whole; therefore, it does not reproduce its contents as, for example, imagination does.

Time-consciousness not only accompanies the constitutions of temporal objects of these specific kinds, such as melodies. It is a type of consciousness that is always at work and necessary for all kinds of object-constitution. For example, if we look at a house, we do not see it as a whole, although we intend it as a whole. In fact, what is given is a manifold of perspectives on that house, which we mentally synthesize. At no stage of this perception is the sum total of perspectives ever given; there is always something absent, but we apprehend the absent perspectives simultaneously with the present ones. Perception of an object is always a process of synthesizing different perspectives or sense data; therefore it is spread over a certain period of time. The perception of things exhibits the same necessary temporal structure as the perception of objects that are distributed only in time, like melodies. The problem is to clarify how a consciousness, whose contents are successively and that means temporally distributed, can constitute enduring temporal objects and an objective time.

How Time Is Constituted

Husserl attempted to describe the constitution of time in countless manuscripts. As with all phenomenological analyses, he tries to elaborate the structures and processes that are at work in every act of consciousness but that do not appear in the normal course of objective events within the natural attitude. The constitution of time has three different stages. The first is constitution of the objects or things in objective time; they are constituted in the duration of the present by apprehension of past, present, and future together. The second stage is the basis for the first, the object-constituting sense data or the manifold impressions in their wholeness within a so-called pre-empirical or prephenomenal time. This time is called prephenomenal because its succession is not apprehended. The third and most fundamental stage is the wholeness of the "absolute time-constituting flow of consciousness." All these stages represent forms of reflective acts of consciousness that constitute different kinds of objectivity, such as temporal objects, objective time (i.e., measured time), and personal experiences as objects of consciousness. The problem with this model and that Husserl himself was aware of is that of constitution via reflexivity. This concept may lead to a vicious circle: If the constituting reflexivity is not itself atemporal (which is also problematic), it would need to be constituted at a higher-level reflexivity or consciousness, and so on.

Time-consciousness consists according to Husserl of two different but inseparably united kinds of intentionality: The first one he calls "transverse intentionality" (*Querintentionalität*), which has the function of keeping the past phases of an experience in mind in order to preserve its duration and objective identity. This intention is directed onto the duration and process of the experience. The second kind of intentionality is called "horizontal intentionality" (*Längsintentionalität*) and, this being the fundamental function, it is directed to the whole continuum of the inner flow of time. It functions as self-reflection, or in other words, *the retention of retention*. This intentionality is the necessary condition of possibility for an awareness of time-consciousness, which Husserl calls "absolute consciousness." The contentious question is whether this transcendental form of consciousness is to be understood as temporal or not. If it is understood as temporal, the theory ends up in a vicious circle because the transcendental instance itself would have to be constituted by something, and so on. Husserl tends to define it as nontemporal, thus avoiding this vicious circle. But having just shown that objectivity depends on temporality, how can it be consciousness if it is not temporal? If the absolute consciousness were not temporal, it would not be consciousness of something. Husserl saw this problem in his constitutional theory and did not settle the question definitely.

Later Analyses

In his later manuscripts, which are not yet available in translation, the *Bernauer Manuskripte über das Zeitbewußtsein* (1917/1918) and *Späte Texte über Zeitkonstituition* (1929–1934), he constantly revised his theory. There Husserl shifts the emphasis of his thought from analyses of the inner time-consciousness to its intersubjective conditions. He follows the idea of a universal time-structure, which is the necessary condition for both history and the human life-world (*Lebenswelt*). With the new topic he develops a new method. The former analyses were dedicated to the intentional structure. They described the static relationship between subject and appearances of objects, which he called static phenomenology. Later on he searched for a way in which phenomenology could also explore the conditions for the dynamic process of the flow of consciousness and the constitution of objects. This next step he called genetic phenomenology. The later manuscripts on time exhibit this new direction, as, for example, in his *Die Welt der lebendigen Gegenwart und die Konstitution der ausserleiblichen Umwelt* (1931), in which Husserl follows the thought of constitution beyond the subject into the life-world. With the ontology of the life-world, Husserl examines both the meaning of and necessary conditions for history more closely. From *Ideas,* in which Husserl maintained that the possibility for objective experience lies purely in the subject, in the transcendental function of consciousness, it was a long way until his later work *Cartesian Meditations,* in which he speaks of transcendental intersubjectivity. This shift from idealism to ontology of the life-world was accompanied by the analyses of time. The phenomenology of time therefore is one of the most important topics on the way to a phenomenological philosophy.

Husserl's Legacy

Among Husserl's students were Martin Heidegger and Maurice Merleau-Ponty, who also worked on the problem of time. His influence extended beyond these prominent students, though. He influenced Rudolf Carnap's theory of logical empiricism; Marvin Farber, who introduced Husserl's phenomenology to the United States; Roman Ingarden, who focused on phenomenological aesthetics; Jean-Paul Sartre and Emmanuel Levinas, two of the most important phenomenologists in France; and Edith Stein. Husserl was also a source of inspiration to Jacques Derrida, the analytic phenomenologist Hubert Dreyfus, and many phenomenological philosophers in Germany and North America.

Hutton, James (1726–1797)

James Hutton was a Scottish geologist, chemist, and naturalist noted for formulating the uniformitarianist doctrine and the Plutonist school of thought. After short careers in law and medicine at the University of Edinburgh, he followed his interest in chemistry and the nascent science of geology. He analyzed metamorphic and igneous rocks at Glen Tilt in the Cairngorm Mountains in the Scottish Highlands and layers of sedimentary rock at Siccar Point on the Berwickshire coast, east of Edinburgh. After these studies, he noted that the origins of sedimentary and igneous rocks are different and formulated theories on the earth's origin that paved the way for modern geological science.

Hutton began a dispute with the popular Neptunist school, which suggested that all rocks developed by precipitating out of a single great flood. After studying the Devonian Old Red Sandstone along Scotland's coast, he realized sedimentary rocks originated not from a single flood but a series of successive floods. He established what became known as Hutton's Unconformity. Hutton reasoned that there must have been several cycles of depositing sedimentary layers, with each cycle involving deposition on the seabed, uplift and erosion, and new deposition on the seabed. He suggested that the stratigraphic record clearly indicated gradual geomorphologic processes throughout the earth's history.

Moreover, Hutton found granite penetrating metamorphic schists at Glen Tilt. This indicated that the granite had been molten in the past, suggesting that granite formed from the cooling of molten rock and not precipitation out of water. The suggestion that plutonic and volcanic activity were the sources of rocks on the surface of the earth replaced Abraham Werner's Neptunism theory, which claimed that rocks had originated from a great flood and were basically sedimentary in origin.

Hutton concluded that the history of Earth can be explained by observing the geological forces now at work. This is the basis of uniformitarianism, the doctrine that assumes that the natural processes of the past are the same as those that can be observed operating in the present: "the present is the key to the past." The theory of uniformity is one of the most basic principles of modern geology. It contrasts with catastrophism, which states that Earth's surface features originated suddenly, through catastrophic geological processes (e.g., the biblical flood) that were radically different from current processes. Because of these hypotheses, Hutton was accused of atheism and poor logic, especially by Richard Kirwan, an Irish scientist who supported the catastrophist theory. Note, however, that many catastrophic events (e.g., earthquakes, glaciations, hurricanes, tsunamis, volcanic eruptions, meteoritic impacts, etc.) are perfectly compatible with uniformitarianism.

In 1795, Hutton summarized his views in a major work, *The Theory of the Earth,* where he affirmed: "Earth is very old and present-day geological structures formed slowly by processes observable today, such as erosion and deposition." Hutton's theory was first presented at meetings of the Royal Society of Edinburgh in 1785, and published in Volume I of the *Transactions of the Royal Society of Edinburgh,* 1788. Two years before his death, Hutton published *The Theory of the Earth* in two volumes, consisting of the 1788 version of his theory with slight additions. In this work, Hutton compiled material on various subjects previously published, such as the origin of granite. His ideas influenced Charles Lyell's principles of geology, which in turn influenced Charles Darwin's theories of adaptive evolution.

Huxley, Thomas Henry (1825–1895)

Within a short time of its 1859 publication, Charles Darwin's *On the Origin of Species by Means of Natural Selection* evoked a wide variety of reactions. Many of his readers enthusiastically embraced natural selection as the elusive mechanism that explained the process of evolution, while others recoiled from Darwinian naturalism, which seemed to obviate divine involvement and purpose. Responses came from all quarters—scientists, philosophers, theologians—and the concept of evolution soon made its way into almost every academic discipline. Because of his temperament and bad health, Darwin shunned the limelight, especially public confrontation. Thomas Henry Huxley, one of Darwin's closest friends and confidants, entered the debate about evolution with a more combative spirit and quickly earned the nickname "Darwin's Bulldog." No epithet was given more deservedly. Though he did not agree with every aspect of Darwinism, Huxley advanced the arguments that related to evolution—its tempo and mode—through his knowledge of comparative anatomy and paleontology. In Charles Lyell and the writings of other geologists, he and his peers found the long stretches of geological—or evolutionary—time needed to produce the vast, fascinating array of extinct and living species. As Huxley conducted research on several broad fronts, he promoted an agenda of change and made a significant impact in science, education, and society at large.

Thomas Henry Huxley (usually referred to as T. H. Huxley) was born in 1825 in Ealing, a small village west of London, and grew up under humble circumstances. Like Dickens, Huxley obtained most of his early education through voracious and wide reading. After a medical apprenticeship, he received a scholarship to study medicine at Charing Cross Hospital (London). Huxley gave special attention to anatomy and physiology and completed this preparation in 1845. In a manner that has some parallels with Charles Darwin's experience on the *Beagle,* Huxley entered the Royal Navy as an assistant surgeon on the *HMS Rattlesnake,* which sailed to Melanesia and surveyed Australia's coast. On a cruise that lasted nearly 4 years (1846–1850), he—also taking on the duties of amateur naturalist—observed a wide range of wildlife and human cultures. While on this journey, Huxley sent detailed studies of invertebrates back home and, upon returning to England, was elected a Fellow of the Royal Society. In 1854, he left the navy and became a lecturer in Natural History at the School of Mines, in London, where he launched his lifelong study of and writing about various topics in comparative anatomy, paleontology, and related disciplines. Over the next 4 decades, T. H. Huxley held many positions in educational and scientific organizations and institutions (including the Anthropological Institute and the British Museum); he also accepted a number of government appointments that drew upon his expertise. Huxley won many awards and promoted scientific research (especially in the lecture hall and laboratory) and publications (and helped start the journal *Nature*). Throughout his career, he identified enemies (scientists, churchmen, and politicians) and attacked them vigorously through the spoken and written word. Along the way, Huxley, known in his intimate circles as "Hal," was devoted to his family, loyal to his scientific colleagues, and committed to improving the situation of the working class.

As was true for many scientists of his era, T. H. Huxley was interested in—and later obsessed with—the lively discussion concerning evolution, even before Darwin published *On the Origin of Species*. Many participants in this dialogue influenced Huxley, one way or the other, at some point in his own intellectual development (e.g., Chambers, Cuvier, Etienne Geoffrey Saint-Hilaire, Haeckel, Hooker, Lamarck, Lyell, Marsh, Spencer). K. E. von Baer, the father of embryology, helped Huxley bring order to his biological worldview through the study of fixed types. Even though he became Darwin's ardent defender and champion, Huxley never fully accepted his friend's fundamental claim that the slow process of natural selection could transform one species to another. Huxley, the scientist, insisted that he needed experimental proof that this mechanism could produce such a powerful transmutation. He also thought that Darwin restricted himself too much by insisting on gradual changes, since Huxley believed that changes could occur "by jumps" (*per saltum*). (Though based on considerably less data, this debate anticipated in some ways the modern discussion concerning "punctuated equilibrium," itself a form of natural selection.)

Although he argued with scientist and churchman alike, Huxley saved some of his most potent venom for the church. He rejected any form of special creation and insisted that a logical, scientific approach would not allow any sort of divine involvement or plan (as held by Adam Sedgwick, Louis Agassiz, Asa Gray, and many others). As a student and admirer of Hume, Huxley's rational, scientific naturalism—supported by his self-professed "agnosticism" (a term usually attributed to him, though others defined it differently)—brought mixed reactions from Rome and the Anglican Establishment. Huxley successfully devoted himself to the task of deflating the church's power and influence in certain aspects of British society, including the universities (Oxford and Cambridge, in particular) and scientific education and research. Indeed, one of the most famous events in the history of science took place at Oxford's Museum of Natural History in the summer of 1860, when Darwin's Bulldog briefly debated Bishop Samuel Wilberforce about evolution. Much (though not all) of Huxley's (and Darwin's) disdain for Richard Owen, a leading comparative anatomist and paleontologist at the British Museum, resulted from the latter's stubborn reference to a divine plan—what some might call intelligent design today.

Whatever course the 1860 Huxley–Wilberforce debate took—and accounts vary a bit—it is clear that sparks flew with reference to the subject of human descent from apes. This subject remained pivotal for T. H. Huxley, as evident in the 1863 publication of what many regard as his most important book, *Evidence as to Man's Place in Nature*. In this same year, Charles Lyell published a volume on this topic, *The Geological Evidence of the Antiquity of Man*. Both Huxley and Darwin counted on Lyell's earlier discussion of "geological time" (though Lord Kelvin objected to Lyell's uniformitarianism) but, of course, nobody in that era had access to the inventory of fossil specimens known today—much less the modern science of genetics. Huxley's study antedated Darwin's 1871 book, *The Descent of Man and Selection in Relation to Sex*, though the former writer said little about the causes of change. Huxley defeated Owen in a debate concerning human and gorilla brain anatomy and insisted, as he did in his encounter with Wilberforce, that the ape's human descendants should feel no shame because of their common ancestors. He held this view at a time when Europeans had limited knowledge of the gorilla. Nevertheless, from Huxley's perspective, human beings were part of the animal kingdom and shared a "pedigree of prodigious length," and the frontispiece in *Man's Place in Nature* (which depicts a human skeleton followed by a gorilla, chimpanzee, orangutan, and gibbon) secured its place in the iconography of science. For Huxley, and his contemporaries, whose outlook was formed, in part, by the place they occupied in the British Empire, the "savages" who lived in remote corners of that empire served as more recent, albeit stone-age, specimens in the same human family tree.

Huxley's study of paleontology led him to accept the transmutation of species, though he did not believe that Darwin's gradualism was reflected in the fossil record. Darwin also recognized this weakness in his argument. The *Archaeopteryx* and *Compsognathus* fossils offered intriguing illustrations of the transition from reptiles to birds, and other aspects of the fossil record helped Darwin and Huxley identify similarities and delineate the continuity between species. Othniel C. Marsh, paleontologist at Yale's Peabody Museum, introduced Huxley to *Hesperornis,* another bird fossil that fueled the latter's speculation about dinosaur–bird evolution. Huxley's knowledge of fossils (including other dinosaurs) and a close reading of Ernst Haeckel's two volumes on *Morphologie* allowed him to see family trees—a genetic connection between the past and the present. T. H. Huxley found special significance in his proposed sequence of horse fossils, also contained in the Peabody collection.

In his 1859 letter to Charles Darwin, Huxley expressed his willingness "to go to the stake" (figuratively speaking by their day!) in support of evolution. He remained loyal to his good friend and continued to promote the cause after Darwin's death, in 1882. Indeed, Huxley's entire career reflects the curiosity and tenacity that allowed him to achieve greatness from such a humble start in life. For Darwin's Bulldog, even the piece of chalk (formed from the remains of countless microorganisms) that a carpenter carried in his pocket reflected the earth's antiquity; his enthusiasm for learning about that past provides a good example even today.

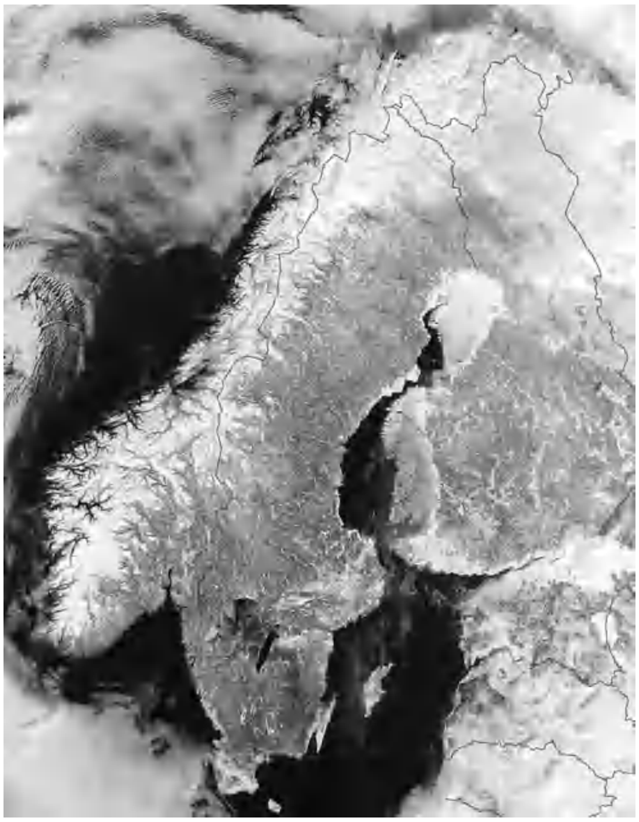
Ice Ages

The most recent ice age can be considered the last million years of geologic time—the Cenozoic era, the latter part of which comprises the Pleistocene and Holocene epochs, which include the most recent ice age. There is evidence, however, that other ice ages occurred much earlier in time, although their existence and extent are more difficult to determine. Evidence of ancient climate change, which covers a range in temperatures from tropic to arctic, is mostly found with fossil evidence. For example, a reef complex and marine invertebrates tend to indicate a tropical area, while mastodon fossils show a cold environment. Thus, knowledge about the ice ages depends to some extent on the study of fossils.

At present, we know of six ice ages. The oldest two known occurred during the Precambrian era, more than 570 million years ago; one of these may have extended into the early Cambrian era. The next oldest ice age occurred during the Permian period and had a time span of about 55 million years, beginning about 280 million years ago. The next ice age came in the early Cretaceous period and another in late Cretaceous, but both were rather limited in extent. The span of time between the early and late Cretaceous ice ages is about 71 million years, beginning about 136 million years before the present (BP). The present ice age began about 1 million years ago, and because glaciers still exist but are receding, *it* can be considered an interglacial stage, presuming another glacial stage is forthcoming.



The Scandinavian Peninsula is a landscape that was largely shaped by glaciers over the last ice age. The moderate resolution imaging spectroradiometer (MODIS) instrument aboard NASA's Terra satellite captured this image of the Scandinavian Peninsula on February 19, 2003. Along the left side of the peninsula one can see the jagged inlets (fjords) lining Norway's coast. Many of these fjords are well over 2,000 feet (610 meters) deep and were carved out by extremely heavy, thick glaciers that formed during the last ice age.

Source: Jacques Descloitres, MODIS Rapid Response Team, NASA/GSFC.

The ice ages of the Cryptozoic eon might be difficult to imagine, but glacial till or tillite with a thickness of more than 500 feet has been identified, as have areas with grooved, striated, and faceted boulders, dating from middle Huronian time during the Proterozoic era in Canada, north of the present Great Lakes, extending more than 1000 miles in diameter. Also, ancient tillites have been found in Manitoba, eastern Greenland, and northern Utah, where layers of tillite with other formations have a thickness greater than 12,000 feet and could be a part of the Cambrian. This type of ice age evidence is also found in southwest Africa, as well as the Transvaal, the Katanga, Griqualand, and South Africa. In Australia, the Flinders Range shows tillite more than 600 feet thick. Ancient tillites are also found in northeast China, and northwestern and eastern India, dating from the end of the Proterozoic. With only tillite to show the location of the glaciation, and without fossil evidence from the Precambrian, it is impossible to estimate the time periods for these occurrences, except that these ice ages, with perhaps others not yet known, occurred approximately from 500 million to 2 billion years BP. So, at least two ice ages are presumed to have occurred in the Precambrian eras.

The ice age of the Permian period was mostly in the southern hemisphere. Primarily consisting of ice sheets, the glaciers covered a large part of southern Africa, portions of Nigeria, Uganda, and the southern tip of Madagascar. Three small portions in India, three areas in Australia, and six sections of South America were also covered with glacial ice. These areas show striated, grooved, and polished rock, with adjacent tillite formations sometimes greater than 100 feet in thickness. These locations appear to have been glaciated repeatedly, all moving in a northerly direction lying within 20° to 35° of the equator. It is likely that these land masses were much farther south than they are at the present time, giving rise to the acknowledgment of continental drift. That is, ice sheets in areas of India and Nigeria that are now north of the equator were well south of the equator in Permian times. Fossils formed during the Permian have been found near the glaciated areas. Especially noted were the small, hardy tongue ferns, *Glossopteris* and *Gangamopteris,* surviving the increasingly harsh climate. These fossils tend to confirm the specific time of the Permian ice age.

The ice age during the Cretaceous period, again, was mostly in the southern hemisphere during Aptian time or in the Late Cretaceous. This is when the dinosaurs ceased to exist, during the Laramide disturbance. Thus, the end of the Mesozoic era and the beginning of the Cenozoic era, about 70 million years BP, is adequately marked. It is noted that the plateau of eastern Australia was ice-capped, with glaciers flowing toward the west into the sea. Icebergs also calved into an inland sea to the east.

During the Cenozoic era, the most recent and well-known ice age occurred. The Pleistocene epoch had four ice ages, or in some accounts, one great ice age with four separate ice advances separated by interglacial stages. Using North American terminology, beginning with the Nebraskan stage about 1 million years ago and lasting about 100,000 years, global warming, or the Aftonian interglacial stage, was about 200,000 years in length. Then, the Kansan stage of glaciation began and lasted for about 100,000 years, followed by the Yarmouth interglacial stage, which lasted for 310,000 years. The Illinoian stage was only about 100,000 years in length, but it appears to have the greatest ice coverage of the four advances during the Pleistocene. The Sangamon interglacial stage was about 135,000 years long; this was the shortest of the three interglacial stages. The Wisconsin stage began about 55,000 years ago and ended a mere 11,000 years ago with the advent of the present interglacial stage, which is known as the Holocene epoch. It is known that the Wisconsin glacial stage had four distinct ice advances and recessions, making a complex landscape across the Midwest of the United States with the same being true in Europe and Siberia.

It is generally accepted that during the last million years or so, crustal movement has been poleward in the northern hemisphere, and that the continents whose shapes and location we know today were different long ago. These are all, of course, geological concerns involving time. Also to be considered are meteorological concerns, which involve the cyclical changes in temperature of land, sea, and atmosphere. At present there is a warming trend that began an estimated 11,000 years ago. It is questioned whether we are at the end of the ice ages or merely between two glacial ice advances. If the global atmospheric temperature decreased a mere 5° C, another ice advance would be likely to begin. How long is this warming trend to last? How has humankind affected this warming trend? What effect will it have if we are still in the Pleistocene ice age or at the end of it? There are more questions than answers. Perhaps significant, however, is that the occurrences of the six known ice ages are spaced closer in time toward the present.

Approximately 4,500 to 5,000 years ago, ice covered all of Minnesota; it had been receding from Iowa since about 2,800 years earlier, although ice had reached as far south as northern Missouri. Today the last vestige of this ice is the arctic polar ice cap, which is continuing to recede. As the ice receded, vegetation and wildlife followed, with aborigines migrating northward from the southern climes. So it is today with nations looking for environmental resources where the ice is melting. Since the shortest known interglacial stage is the Sangamon, which lasted 135,000 years and ended 55,000 years ago, it can be expected that a phase of global warming is just beginning and will be here for tens of thousand of years more, whether affected or not by the activities of humankind.

Idealism

The term *idealism* refers to any philosophical system or thesis that emphasizes the mental (idea) or the notion of very high or preeminent value (ideal). Because minds evaluate, it is possible to imagine a deep relationship between these two very different criteria. There are some connections, but clarity demands that they be understood separately. Only the emphasis on the mental yields a distinctly idealist conception of time.

When emphasizing value, *ideal, idealistic,* and *idealize* serve many functions. For example, norms and goals are often called ideals. On that basis, some moral attitudes such as optimism, commitment, and cheerfulness are deemed idealism, as in "the idealism of youth." Similarly, in international relations, idealism refers to a policy or posture obligating a state to promote higher aims among nations, such as peace, justice, cooperation, open borders, or democracy, while *practical* idealism refers to a position between that kind of idealism and what is known as *realism,* which refers to a state's selfishness in international affairs.

A second line of usage takes off from the fact that whatever would fully satisfy a desire is called ideal. Hence, in aesthetics, idealism has to do with representing things as we would like them to be (idealized) rather than as they are. With a little pejorative shading here, *idealist* calls out a vice. Thus, in ethics, the idealist is one whose standards are unrealistically high, or who is too confident about the virtue of a person or line of action, or perhaps altruistic to a fault. A system of ethics might be called idealistic if it sacrifices too much for the sake of a particular principle; or if it elevates any aspect of moral life too high, for example, sympathy at the expense of autonomy, but especially the spiritual or rational at the expense of the sensual or immediate; or if it believes too much in the goodness, or perfectibility, of human nature; or if it overestimates the moral efficacy of a line of causation, such as instruction, role models, prayer, meditation, sobriety, free markets, self-denial, the individual, the mass, the ego, the id, or rationality. Slightly more pejorative shading renders the idealist an idle dreamer of utopias, or an impractical adherent of some perfect, best, or ultimate in some domain. At the deepest levels of pejoration, *ideal* gives way to *idea,* in the sense of imaginary, and the idealist is primarily a fantasist.

Philosophy and Idealism

When the emphasis falls on mind, rather than value, there are both broad and narrow uses.

Most broadly, idealism is the negative of naturalism, materialism, or realism. Both *naturalism* (which abjures supernatural explanations) and *materialism* (which asserts that reality is ultimately physical) relegate the mental to a nonbasic, nonfundamental ontological status. Idealists do the reverse. Realism holds that the world exists independently of thoughts about it. Idealists typically deny some or all of that. However, there are systems of idealism that grant a good deal of realism, and so the most common and broadest ways of thinking about idealism treat it as the negative either of materialism or naturalism, or both.

For Karl Marx, it is the negative of materialism. If materialism is built upon the particular, the describable, and the sensuous, idealism stresses the universal, the indescribable, and the supersensuous. Where materialism posits the mechanistic, idealism introduces the teleological, and where it abjures evaluation, idealism inserts appraisals. Taken in this way, idealism includes all theses and systems that ultimately ground reality in the animate or the mental, whether taken as idea, mind, will, ego, nous, logos, word, text, absolute, God, life force, or earth turtle. Every kind of theism in which something animate is the source, ground, or essence of nature is idealism. Every account of causation that introduces teleology is idealism. Every ascription of a value to the essence of things is idealism. In this sense, the history of philosophy is very much a history of idealism, if only because it has been rare for thinkers to adhere to strict materialism and to forgo teleological and normative language in their descriptions of the world. When they have deviated into materialism, many have settled on a dualistic view in which it inevitably became all but impossible to allow the material equal footing with the ideal, making them realists who maintain a form of idealism.

Such views are often called *realistic idealism,* which refers to any doctrine that recognizes the existence of nonmental, nonideal entities but relegates them to a subordinate status as compared to the ideal. Theistic schools of this sort allow some category of nonmental existence independent of the divine mind but also hold that the divine created it, perfected it, controls it, or is coeternal with it. Nontheistic schools include Plato's system, in which timeless, disembodied ideas are organically united in the idea of the Good. Insofar as the world of particular things is downgraded into a mere imitation of these transcendent universals, Plato's system is an instance of realistic idealism. Another example is psychological idealism, which is the doctrine that ideas or judgments cause thoughts or behaviors. Like Plato's system, this doctrine is understood as denying either naturalism or materialism, or both, but not realism.

Epistemological idealism is the view that all entities other than minds are exclusively noetic objects, meaning that they have no reality apart from being perceived or thought by a mind. Edmund Husserl attempted to systematically think through a hypothetically couched form of epistemological idealism. In his phenomenology, the essences of objects, including the self, the other, time, and causation, are methodically treated *as if* they were exclusively noetic, apart from any other status they might actually have. A nonhypothetical system is found in George Berkeley's doctrine of immaterialism, where to be is to be perceived, and all that exists must be either perceiver or perception. Another is the transcendental idealism of Immanuel Kant, in which knowledge is wholly a product of the logical self or of transcendental unity of apperception.

In the existentialism of Martin Heidegger, learning is giving oneself to oneself. In postmodernism, there is nothing outside the text, and there are signifiers but no signified, both of which directly imply that our minds can encounter only thought. Semantic idealism is the thesis that our descriptions refer only to ideas rather than to things, so that, for example, the tautology, "When I speak of my right hand, it is my right hand of which I speak" is false, and instead, "When I speak of my right hand, it is an idea of my right hand of which I speak" is true. The implausibility of semantic idealism has been a frequent challenge to forms of epistemological and psychological idealism that rely on or imply it.

In its narrowest senses, *idealism* is variously qualified so as to sort and organize metaphysical outlooks. For example, impersonalistic idealism grounds the world in unconscious, spontaneous mental energy, whether as life force, precognitive urge, or primordial will. Personalistic idealism, also known as personalism, grounds the world in a self-conscious or purposive principle, such as nous, logos, or ego. The relationship between the mental world ground and individual, finite minds is crucial.

Monistic idealism holds that each finite mind is a mode, aspect, or projection of the One. Pluralistic idealism grants varying degrees of freedom, autonomy, privacy, uniqueness, and causal independence to the thoughts and acts of finite minds. With regard to their means of accounting for the natural world, schools of idealism are either subjective or objective. *Subjective idealism* holds that the natural world is a projection of our minds and appears to imply solipsism. *Objective idealism* identifies the natural world with the thoughts or acts of the world ground. Given these distinctions, Arthur Schopenhauer's philosophy, which grounds the world in blind will and affirms that every lion is one lion, can be understood as an impersonalistic, monistic, objective idealism. Schopenhauer's primary influence, the Vedic philosophy, which teaches that the finite self is a moment of the impersonal *Brahman,* is also an impersonalistic, monistic, objective idealism.

Schopenhauer's antipode, G. W. F. Hegel's philosophy, which treats thought as the ground of the world, freedom as the condition of thought, and self-consciousness as the condition of freedom, obviously grounds the world in a self-conscious principle, and it is thus a personalistic, pluralistic, objective idealism. Henri Bergson's philosophy of *elan vitale* is an impersonalistic, pluralistic, objective idealism, a status it shares with Friedrich Nietzsche's philosophy of will to power.

George Berkeley's immaterialism is often described as "subjective idealism," but that cannot be the case as the term is defined here. Berkeley denies only matter in nature, not nature's independence from finite minds. Objects in nature turn out to be exclusively noetic in his system, but they are not projections of our minds, but rather thoughts perceived in the mind of God, a view echoing prior work by Arthur Collier and John Norris. Because objects in nature are accounted for in terms of the acts of God's mind, rather than the acts of finite minds, Berkeley is an objective idealist with a personalistic world ground and a pluralistic outlook on finite minds.

A version of subjective idealism is found in the "windowless monads" of Gottfried Leibniz, which perceive the real world by perceiving only themselves. A more recent example is the decidedly antirealist school of postmodernism. Given its denial that our minds can encounter anything other than thought, the question becomes whose thought, our own or that of another, is encountered in the objects of nature. The postmodernist cannot offer us an encounter with the thoughts or acts of an independent world ground, because that would mean encountering the signified rather than the signifier. With the only route to objective idealism thus blocked, the postmodern idealist must be a subjective idealist for whom the natural world is a mental projection conditioned by our backgrounds and differences. Because these backgrounds and differences condition the world, postmodernism is an impersonalistic, notably monistic, subjective idealism, in which an unmistakable degree of monism among finite minds is achieved through the notion of impersonal, collective construction of reality—to be is to signify as a group member.

In the philosophy of mind, *hylozoism,* the view that matter is alive, and *hylopathism,* the view that matter is sentient, or that whatever is ontologically more basic than consciousness, such as neurons and their building blocks, already contain the essentials of consciousness, are impersonalistic idealist views. Alfred North Whitehead's *panexperientialism,* which holds that the fundamental constituents of reality are experiences, is somewhat more personalistic than these, as is *panpsychism,* which attributes mind to matter. *Panentheism,* which holds that the One both transcends and is imminent in the universe, and *pantheism,* which identifies the natural world with the One, are yet more personalistic. The *occasionalism* of Nicholas Malebranch, in which natural causation is an illusion and God is the sole cause of all events, including all human acts and cognitions, is an example of a highly monistic causal pantheism, the omnisufficiency of a personal One, in the philosophy of mind.

Time and Idealism

Because idealist thinking is found in all ages and languages, the term *idealism* is frequently restricted so as to sort schools according to historical criteria, for example, as 19th century, modern, or ancient idealism; German or British; Vedic or Buddhist; philosophical or religious. By the same token, there is no single idealist attitude pertaining to time. History's various gods and goddesses of time, such as Chronos, Aion, Kali, and the figure of Father

Time, express personalistic views, while a World Tree and a World Snake express impersonalistic views. Personalistic creationism in this area has often stumbled over the fact that the notion of a creator of time looks incoherent, because a creator of time must change from a state of not creating time to a state of creating time, and thus time must exist (as the medium of change) before it is created.

In philosophy, there has been one characteristically idealist thesis about time, known as the *ideality of time* thesis, which holds that time is not to be found outside of mind, or that it is exclusively noetic, or phenomenal, a view expressed as early as Antiphon the Sophist. Plotinus held it as well. Its modern proponents, in their various ways, include Leibniz, Baruch Spinoza, and most of the school of 19th century German idealists, including Schopenhauer, Hegel, Johann Fichte, and Friedrich Schelling. Kant held that space and time were necessary, a priori preconditions of understanding. The external world is necessarily represented in space and time, while the inner world of thought is necessarily represented temporally. In both cases, time is empirically real but transcendentally ideal, meaning that it is an actual datum of experience, though we can have no reliable conception of it outside of experience. In contrast, Nietzsche probably denied the ideality of time in favor of a real eternal return. More recently, many of the existentialists who were inspired by Husserl's work entertained phenomenological versions of the ideality of time, including Heidegger and Karl Jaspers. In the school of British Idealism, F. H. Bradley and J. M. E. McTaggart embraced the ideality of time thesis. The latter famously argued for the unreality of time and produced a system that was so pluralistic that there was no God or One in it. Instead, McTaggart grounded the world in the thoughts of a community of immortal spirits.

Belief in the ideality of time has often been held as a consequence of the belief that all things are ideal, but it has also occurred, for example in Kant and McTaggart, that belief in the ideality of time thesis has been the basis on which a more general idealism was erected and justified.

Idealism's Critics

Critics of idealism have been many, beginning at least with Aristotle. The most notable German critics are Kant and Nietzsche. Kant argued against all forms of thought, including all forms of idealism, that move beyond the limits of categorical experience to predicate the thing in itself. Nietzsche suggests that Kant's transcendental idealism is based in the faulty argument that a priori synthetic truths are possible by virtue of a faculty, and he describes Hegelian idealism and Kantian skepticism as delaying tactics employed in a largely theological struggle to prevent the emergence of a naturalistic world view.

In Britain, G. E. Moore and Bertrand Russell led a revolt against the breed of Hegelian idealism that was then dominant in English philosophy. It was the seminal event in the birth of the school now known as analytic philosophy.

Ides of March

In the complex world of the Roman calendar, each month had a day called its *ides*. In March, May, July, and October, the ides fell on the 15th of the month. In the remaining months, the ides fell on the 13th. Ides comes from the word *iduare,* which means, "to divide" and literally signified the division of a month into two equal parts. The Roman calendar divided each month into *kalends, nones,* and *ides,* each celebrated in their own ways, indicating lunar events, and serving as a calendar for the common citizens. The ides was a day traditionally marked for ritual offerings and sacrifices.

Religious and political leaders kept calendars private and were often adjusting the length and structure to remain in sync with the lunar and seasonal changes. In the Roman and Julian calendars, the term *ides* was commonly used, equivalent to using such modern terms as *next week, today, tomorrow,* or *yesterday.*

The ides of March took on a whole new meaning in the year 44 BCE. It was on this day that Julius Caesar, emperor of Rome, was assassinated by a group of nobles in the Roman Senate. William Shakespeare captured this historic assassination in his play *Julius Caesar.* In Act One, Scene Two, a soothsayer proclaims a warning to Caesar in the infamous line, "Beware the ides of March."

After the Julian calendar, inspired by Julius Caesar, displaced the Roman calendar in 46 BCE, the term *ides* was used only colloquially to denote the middle of the month. Those living under the traditional Roman calendar most accurately interpreted the ides as the 15th of the month. With the passing of time, the expression "beware the ides of March" came to signify the prediction of doom, much like the aura of superstition that associates bad luck with Friday the 13th.

Immortality, Personal

Personal immortality is best understood as the belief in the actual survival beyond physical death of the core element of our personality or consciousness—often called the soul—for an indefinite period. The primary assumption of this belief is that the core element of consciousness, or soul, is entirely distinct from our body, and so can be removed from it on the body's death with no compromise in quality or essence. The consequences of belief in personal immortality on one's view of time are profound and involve a comprehensive rejection of temporality. It is also considered of fundamental importance in the development of religion.

Beginnings

It seems apparent that some of our predecessors' earliest speculations revolved around death and its consequences. The existence of burial sites among Neanderthals from 60,000 years ago and early *Homo sapiens* from about 35,000 years ago suggest that death was believed to be a transitional state. The practice in primal societies of killing off aging people was due, in part, to the supposition that their bodies, not being yet decrepit, would be useful to them in the afterlife. And the mutilation or eating of enemies was done with the same view in mind; the destruction of their bodies so as to cripple their ability to exact revenge from beyond the grave.

Similar views carried on in the early civilizations. The Egyptians, for instance, held high store on immortality, but their extraordinary efforts to preserve the physical body with processes like mummification suggest they could not conceive of immortality without a physical body. The coronation of the pharaoh was held to coincide with either the rising of the Nile in the early summer or receding of the waters in autumn when the fertilized fields were ready to be sown. As part of the coronation the pharaoh would reenact the deeds of Osiris, who represented the life-giving waters of the Nile. Beliefs about Osiris embodied the cycle of birth, death, and rebirth around which Egyptian life revolved. And from this cycle came the promise of immortality, which for many centuries was the preserve only of the pharaohs but eventually became available to anyone who could afford the expensive rites and observances.

Asian Traditions

Indian notions of immortality resonate to a different beat, bound up as they are with the idea of rebirth. It is one thing for the soul to survive death, but immortality is another thing altogether. The Vedas spoke simply of an afterlife presided over by the god Yama, but ideas of rebirth developed later. In what has become understood as the quintessential Hindu view, the soul will undergo an almost countless number of rebirths and, along the way, gradually rid itself of the life-clinging vices of greed, hate, and delusion. The final aim in Hinduism is *Moksa,* or liberation. Here and only here is true immortality achieved, but at the cost of having shed all traces of existence apart from the universal whole into which it has merged. Much the same is true of the Buddhist notion of *nibbana,* or in Sanskrit, *nirvana.*

In China, Confucianists and Taoists alike shared the Indians' suspicion of the egotism thought to underlie a desire to live forever, but they had no thought of rebirth, thinking instead that we have but one life to live. One tradition of thought expressed this well by speaking of the "three establishments." Instead of yearning for immortality in heaven, they advised we focus more on being remembered well here on earth, which could be done in any of these three ways: *establish virtue* to be remembered as an upright and honest person; *establish achievement* to be remembered by what one achieved in life; and *establish words* to be remembered by any written legacy one may have left. The Asian traditions, then, do not value personal immortality. In fact, their core insight is to rid oneself of the delusions that would presuppose such a goal to be worthwhile.

The Middle East and Judeo-Christian Traditions

As long as the physical body was bound up with the afterlife, as in Egypt, thinking on personal immortality could only go so far. It was the Persian sage Zoroaster who is credited as the first to associate personal immortality with the beliefs and actions of one's life. As part of a rebellion against the polytheism of the Persia of his day, Zarathustra posited a universe characterized by a cosmic struggle between good and evil. The good was exemplified by Ohrmazd and the evil by Ahriman. While Ahriman owed his existence to God, he had of his own free will chosen the evil path. Zarathustra taught that human beings can also choose to follow the righteous or the evil path and that our immortal destiny depends on the decisions we make.

As is now widely recognized, Jewish, and later Christian, religious concepts owe a heavy debt to Zoroastrianism. Jewish eschatology was primarily concerned with the fate of the nation, but the collapse of the Jewish nation and the Jews' exposure to Zoroastrian beliefs while in exile in Babylonia in the 6th century BCE introduced new ideas of personal immortality linked to the passionate belief in the justice of God. It is likely that the development of personal horoscopes in Babylonia in the 5th century BCE was due to the influence of Persian doctrines of personal immortality.

Until the exposure to Persian ideas on personal immortality, there was little discussion in the Jewish tradition of what happens after death beyond mention of a dim underworld called Sheol, to which all departed go, whether righteous or wicked. *Sheol* originally referred simply to the collective graves of the tribe. Sheol was a sad place where the soul wanders aimlessly, an enfeebled remnant of the living person. After the Persian ideas became available, some evidence exists that views developed to include the possibility of intervention from Sheol into worldly affairs. These ideas were resisted by the more learned sections of society, and more skeptical ideas became prevalent.

The other important influence on Jewish thought on immortality was Platonism. Before Plato, little attention had been given to a life after death. The funeral oration of Pericles, for example, makes no mention of an afterlife for those who had fallen in defense of Athens. Popular notions of Hades were much like Sheol: dark, gloomy, and unwelcoming. So when, in the *Phaedo,* Plato argued for personal immortality as experienced by an immortal soul, he was going against the grain of Greek thinking.

As a result of these different influences, it is hardly surprising that Jewish thinking on immortality was not consistent. On the one hand it was believed that at the end of time the soul would be reunited once again with the body and that the righteous and the wicked would receive rewards or punishments accordingly. But alongside this was the idea that the soul, being immortal, survived bodily demise and received its punishment or reward immediately upon death. And then there is the eloquently phrased skepticism of any sort of afterlife, as expressed in Ecclesiastes (9: 3–10).

For first century Judaism, then, the question of immortality was hotly contested, with the Sadducees arguing against it on the grounds that such an idea has little or no scriptural warrant. Against them stood the Pharisees, who were less traditional and more influenced by the Greeks in this respect, and their case won in the end. The influence of the later Greek thinkers, with their notions of an immortal soul for which the body was simply the vessel, can be seen in the thought of Philo of Alexandria (c. 20 BCE–c. 50 CE).

Christian teaching on immortality inherited some of the ambiguities of Judaism, but Saint. Paul's strong commitment to personal immortality smothered them. Saint Paul was quite clear about the central role immortality had in his theology. "And if Christ be not risen, then is our preaching vain, and your faith is also vain. . . . If in this life only we have hope in Christ, we are of all men the most miserable." (1 Cor 15:14, 19) His strong interpretation of immortality was followed up by Saint Augustine (354–430 CE), whose works were vastly influential in establishing Christian dogma for more than 1,000 years.

But even in Saint Paul there was a certain ambiguity. It is not certain, for instance, that eternal life can be understood straightforwardly as surviving beyond death. Elsewhere Paul speaks of our mortality being clothed with immortality, but once again this is as likely to refer to the eternal life of salvation with no suggestion of personal survival. This more sophisticated argument has not found favor among the vast majority of Christian believers, who continue to believe in their own personal immortality.

It is true, however, that there are two quite different conceptions of immortality in the early church, neither of which was clearly articulated. On the one hand, the belief that with the Second Coming of Christ all the dead will be resurrected requires that they lie dormant until then. But on the other hand, there is the belief that our souls depart from our bodies on death and immediately go to whichever point of repose is allocated to them. In the early years of the church, this distinction did not matter a great deal, because the return of Christ was believed to be imminent. But as time passed and Christ did not return as expected, the problem of this intermediate period between death and resurrection took on a greater urgency, particularly as the promise of immortality constituted its principal point of difference with other religions and with paganism.

Renaissance and Modernity

The importance of the idea to the Christian appeal notwithstanding, major areas of confusion remained for centuries to come. The individuality of the soul—an idea essential to the notion of personal immortality—only became established dogma at the fifth Lateran Council of 1513. But Pope Leo X's effort to enshrine belief in immortality was indication that it was under attack. In the general spirit of inquiry that characterizes the Renaissance, belief in personal immortality was one of the first supernaturalist nostrums to be queried. Of particular interest here is Pietro Pomponazzi's (1462–1525) *On the Immortality of the Soul*. Published only 3 years after Leo's edict, Pomponazzi's treatise looked at the discrepancies between Aristotle's view of the soul and that of official Catholic teaching. In particular, it explored the difficulties in reconciling the status of the perished soul in the twilight zone between death and resurrection. It ended up saying that personal immortality could not be established by reason and could only be believed as an article of faith. His work was publicly burned and he narrowly escaped more serious persecution.

Over the next centuries, thinking on immortality diversified a great deal. Immanuel Kant (1724–1804) devoted much energy to placing immortality as a postulate of the moral law, but almost completely ignored any description of what immortality might be like. A landmark in thinking on personal immortality came from Ludwig Feuerbach

(1804–1872), who was one of the first to articulate a contemporary understanding of immortality. In *Thoughts on Death and Immortality* (1830), Feuerbach argued that the ancient world conceived of immortality as achieved through identification with the state and the people, and it felt no consequent need to denigrate the limitations of a life lived in the here and now. But the specifically personal immortality before a personal transcendent God was a relatively recent development of Christianity, this not having been the main understanding of immortality during the Middle Ages. But, he argued, in the face of the "double nothing" of living people without essences and essences without meaning, the traditional dualism of Christian dogma was no longer viable. God, by this way of thinking, became an alien "other," outside the framework of human love. Instead, the earlier notions of immortality as a social memory and as part of a larger community were now returning to their rightful position.

In the wake of Feuerbach, a variety of naturalistic accounts have been offered. Following on from the ancient Indians and Chinese, 19th and 20th century freethinkers were suspicious of the motives that underlie the popularity of the idea of personal immortality. Nowhere was this more forcefully put than by the American pragmatist thinker William James, who wrote, "The pivot round which the religious life, as we have traced it, revolves, is the interest of the individual in his private personal destiny. Religion, in short is a monumental chapter of human egotism." Many freethinkers of the time thought the same. For example, George Anderson (1824–1915), an English businessman and philanthropist, wrote a poem called "Immortality," which was published in the *Agnostic Annual* in 1897. Anderson understood well the attraction behind claims of personal immortality: "So man's weak vanity was touched and flattered,/And thus he listened to the wondrous tale,/That all creation might be whelmed and shattered,/While He o'er death itself would prevail."

Several attempts were made in the 19th century to reconcile belief in immortality with the naturalistic worldview, the most influential of which was the phenomenon of spiritualism, which attracted considerable support between the 1850s and the 1920s. Through séances run by mediums, it was widely believed that contact could be made with the deceased. The more devoted spiritualists were convinced that they had achieved a major scientific breakthrough. Personal immortality was no longer a matter of faith or dogma, but of testable fact. The last great wave of interest in spiritualism happened during the First World War, as grieving family members sought to establish contact with loved ones killed in the fighting. But spiritualism declined after the war, as greater scrutiny of the mediums' practices revealed them to be tricks that magicians could reproduce or even simple fraud.

Other thinkers tried to avoid the question of whether personal immortality is actually true or not. For instance the pragmatist philosopher F. C. S. Schiller (1864–1937) acknowledged that dogmas about immortality were accepted because they were what people want to believe. But he specifically sidestepped the question of whether personal immortality was true and confined himself solely to the value of the belief on a person's conduct and well-being. He went further when he insisted that the ethical argument for immortality remains independent from whatever science may discover. This style of thinking has remained influential among religious progressives.

The most thorough critique of personal immortality from the 20th century was *The Illusion of Immortality* (1935) by Corliss Lamont (1902–1995), an American philosopher who studied under John Dewey. This work went through three editions and remained in print for 40 years. Lamont was not unsympathetic to the motivation behind the wish for immortality, but it was clear to him that immortality was incompatible with a naturalistic account of things. This said, he did more than simply deny the traditional conception of immortality; he also broadened the range of ways we could think about immortality, which involved many more perspectives than simply personal immortality, which relied upon a heavy dualism. Lamont identified *ideal immortality,* or the eternal moment that Spinoza and Santayana spoke of; *material immortality,* where the material that makes us up is subsumed after death back into nature; *historical immortality,* or the simple fact of our existence in time; *biological immortality,* or our continued existence through our children; and *social immortality,* or survival through the memory of our achievements.

An interesting development over the past half century has been an increase in interest in the beliefs of the general citizen on matters such as this. For example, the World Values Survey, which polled people in 74 societies around the world between 1981 and 2001, found a general decrease in belief in personal immortality as societies become more prosperous, although with an interesting anomaly. In agrarian societies, belief was measured at 55%, in industrial societies at 44%, and in postindustrial societies at 49%. The slight rise of reported belief in personal immortality in postindustrial societies may be accounted for by the inclusion of the United States, where the figures are out of alignment with all other postindustrial nations, with its growth of various "new age" spiritualities. Interestingly, this was the only anomaly in an otherwise even decline in all recognized forms of religious belief and expression from agrarian to postindustrial societies.

More recently a wide range of Christian thinkers have reconciled themselves with the naturalistic account of the world and have abandoned the more supernaturalistic interpretations of personal immortality. Many have developed variations of Lamont's ideal immortality to reposition the argument. These, along with the more naturalistic interpretations, mean that immortality has a wider range of interpretations now than at any time in history. In general, however, personal immortality has given way to variations of the nonpersonal immortalities Lamont and others have outlined. And in so doing, time has been handed back its absolute dominion.

Incubation

Incubation refers to the amount of time required in a developmental period. It stems from the Latin root *incubare,* which means to lie upon. This correlates with the term's most common use today, avian incubation. However incubation can also be applied to chemistry, microbiology, medicine, and even ritual.

Avian incubation denotes the time when the parent birds, usually female, sit upon their eggs. The body heat from the parent provides warmth to the growing eggs and maintains a consistent environment, providing constant humidity, shade, and temperature. Some species of bird, such as megapodes, incubate their eggs by burying them, with the eggs receiving warmth from geothermal heat and organic breakdown of vegetable matter. The incubation period varies from species to species, ranging from only 11 days up to 85 days. Some species may also begin incubating at different times of development to either stagger the brood's growth or create a simultaneous hatching.

In chemistry and biochemistry, incubation is the period of time and set of conditions required to maintain a chemical reaction. These condition constants can include temperature, pressure, concentration of reactants and products, and the presence and concentration of a catalyst. By utilizing the proper chemical incubation period, chemists are able to synthesize the highest yield of products in the shortest time.

In medicine, or more specifically pathology, incubation is the amount of time before a patient begins showing symptoms after a pathogen or disease-causing bacterium enters the body. This is often also referred to as the latency period. This incubation period varies for each disease and can range from a few minutes to several years. Generally the incubation period in children is shorter than the incubation period in adults.

Because these diseases are caused by pathogenic organisms, a valuable tool for diagnosing these illness are cultures, including blood, stool, urine, and sputum cultures. These cultured samples are actually grown in optimal conditions in machines called incubators, which can range in size from small tabletop units to those as large as rooms. These microbiological incubators can be programmed to simulate highly specific conditions, including carbon dioxide and oxygen levels, humidity, and temperature. Most incubators are programmed to simulate the internal environment in a human, because pathogenic bacteria usually experience optimal growth in these surroundings.

Another form of medical incubation is done in neonatal intensive care units (NICUs). Here, newborns in critical condition are placed in incubators, which are essentially large open warming units. These provide a constant temperature and oxygen level and a relatively clean environment. More advanced incubators may feature monitoring equipment and pressure capabilities, which help keep premature infants' airways from collapsing. However, this technology has its drawbacks, as newborns in the NICU often experience high noise and light levels, reduced physical contact with humans, and separation from their parents.

In a less scientific sense than the other definitions, incubation may also be applied to the mystical practice of sleeping in a sacred or divine area in hopes of achieving a spiritual enlightenment, whether it be through a dream, vision, experience, or cure. In ancient times, this practice was very common, especially for followers of the Greek deity Asclepius, the demigod of healing and medicine. Several present-day Christian sects and Greek Orthodox monasteries still practice this method of incubation today.

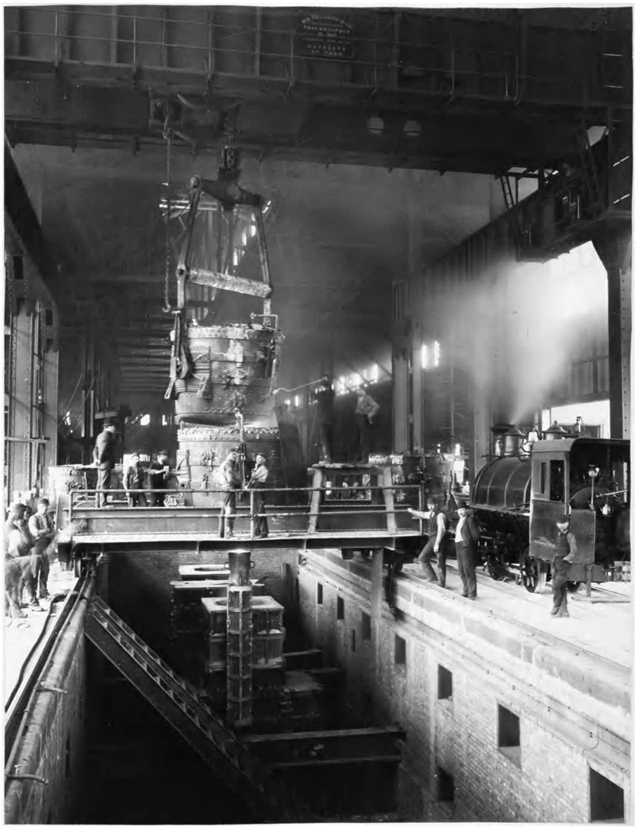
Industrial Revolution

The Industrial Revolution was a period in modern history when the production of goods by hand was gradually converted to methods of manufacture using large machines and assembly lines. This shift is seen by many historians as the force chiefly responsible for the birth of the modern era and for the ongoing phenomenon of globalization that emerged in the 19th century and now continues into the 21st.

The Industrial Revolution began in Great Britain. In 1650 the population of England was approximately 10 million, of which 90% earned a livelihood through farming of one kind or another. In 1821, Thomas Malthus wrote *Principles of Political Economy,* in which he discussed the concern that a lack of moral restraint by the British working class might lead to unchecked population growth. This behavior on the part of some people would create a fall in production, and the world would face a famine. Malthus gave a very gloomy prediction that worldwide mass starvation would eventually occur. In just 200 years, 1650 to 1850, the English population soared to more than 30 million, with less than 20% at work in fields, barns, and granaries. During this time England experienced the first Industrial Revolution, as entrepreneurs and capitalists began procuring the natural resources and labor power to produce goods for profit on a scale hitherto unknown.

The Industrial Revolution succeeded the longstanding agrarian age, which had begun millennia before when much of humankind developed agriculture and gave up nomadic lifestyles. Agrarian societies allowed people to escape from dependence on food sources over which they had no control. In such societies people produced surpluses that could be used to feed new classes of non–food-producers. At the same time, these societies required increasing amounts of land, which led to conflicts over territory. The need to store and defend food supplies and to house non–food-producers resulted in the growth of villages and small cities. Agrarian societies developed extensive division of labor and interdependence.

In *Principles of Political Economy and Taxation,* economist David Ricardo furthered the explanation for the changes that were occurring during the



Homestead Steel Works, *by B. L. H. Dabbs, 1893–1895. Workers watch as a foundry ladle prepares to pour molten iron into ingot molds at Carnegie Steel Company's Homestead Steel Works.*

Industrial Revolution. Ricardo explained the notion of cooperation as a consequence of prosperity in his theory of comparative advantage. Ricardo concerned himself with explaining the factors that caused growth in an agrarian economy. At the time, modern science and technology had not been applied to agriculture, and capital tools such as hoes and plows were of relatively minor importance as productivity inputs. Ricardo argued that the average productivity of labor would eventually decrease. This decrease in productivity would lead to falling wages for workers.

The Industrial Revolution in the simplest terms can be described as the advent of a decline in household production. It started in Britain for several reasons. The increased population provided labor for factories and markets. Britain had a rich supply of raw materials. Britain had many small shop owners that knew how to run a business. The change in production was an economic one, yet over time it became a political one as well as a social one.

Political Thoughts on the Industrial Revolution

The first Industrial Revolution was the impetus that led to the science of political economy. A new way of thinking was needed to explain and justify the social conditions. This began as philosophers in Europe struggled with the fundamental problem of how the individual pursuit of self-interest would lead to the highest social good. According to Arild Saether, theology and the power of the universal church as an explanation for human behaviors were replaced by new theories independent of church doctrines. There was a new distinction between positive and natural laws. Natural law was the manifestation of divine law. This law was revealed through nature based on reason. On the other hand, humankind created the concept of positive law. People needed to create laws to secure peace. New laws were required, because in a natural state everyone has the same equal and unlimited right to everything. With the advent of the Industrial Revolution, social structures changed and continued to develop specialized production of material goods. A continued propagation of the natural law would have resulted in a war of all men against all men, and self-destruction would have resulted. Hence, it was necessary for people to seek an agreement of cooperation and common wealth with each other. Works were written to explain positive laws. Such positive law acquired dominance in the 18th century and was firmly established in the 19th century.

The origins of the early teachings of political science are widely agreed upon. The Industrial Revolution had created a wealthy class of industrial capitalists who had to pay workers at least enough to live on. England at that time had a living wage that depended greatly on food prices. Ricardo advocated trade between countries. Consequently, the Corn Laws were passed. The Corn Laws placed tariffs on grain imports and created export subsidies that kept food prices high and increased the wages that capitalists had to pay. The basis of David Ricardo's theory, accepted in Parliament, was that specialization and free trade were beneficial to all trading partners. Adam

Smith and Ricardo had successfully explained the need and advantages for material cooperation and the acceptance of economic inequalities.

Adam Smith, a Scottish philosopher, wrote *The Wealth of Nations* in 1776; the book was widely accepted as a blueprint for economic activity and has been called the "bible of capitalism." Smith's teaching underscored the way humans reconciled self with others during the first Industrial Revolution. Smith discussed the division of labor as a consequence of social prosperity and people's desire to barter and exchange one thing for another. He explained how people managed to coexist by offering goods and services for sale in quantities that satisfied each other's private wants. Smith described how the invisible hand of the marketplace led to a cooperation that provided productivity and distribution that met the needs of society, and he argued that people would act in their own self-interest to provide goods and services of the greatest possible value. That in turn would allow for one to trade a good or service of a proportional value for another that one otherwise would not be able to receive. Those who produced the best would thrive, while those who provided the wrong good or provided an inferior good would lose out. Smith explained how the Industrial Revolution shaped what became known as the free market.

The free market paradigm provided an incentive for productivity and trade and provided a rationale for people to accept the idea of economic inequalities. Smith in essence justified the unequal distribution of wealth, arguing that in the long run everyone would gain. This notion of inequality was not new to the human race, but the free market explanation was an extension of the new concept of positive law. At the time of Smith's publication, England's Industrial Revolution saw the new manufacturing technologies, the development of more efficient forms of transportation, and the increase in productivity of agriculture that led to a massive movement from the countryside to the city. People in search of work migrated from rural areas to crowded cities and toiled long hours.

In 1875, Karl Marx completed work on the book *Capital* (*Das Kapital*). Marx's treatise developed an alternative understanding of the value of human labor. Marx's work served as an intellectual basis for a different vision of society, one that originated in class conflict, a struggle between labor resources and owners of capital. The labor theory of value, according to Marx, was the value of any commodity that resulted from the labor needed to produce the commodity. Labor provided more value in a day than it was paid. Capital owners were able to extract a profit when labor was used for the production of commodities. This notion proved to be a basis of the controversy as to how cooperation among humans over material value was organized. The philosophy of Marx pointed to the inevitably antiprogressive results of the economic and social inequality that the Industrial Revolution produced. Marx's view of progress was not supportive of the Industrial Revolution and the decline of family production. His philosophy was not based on incentives for people to be productive in order to get their needs and wants met. Marx's work in the field of political economy promoted an egalitarian economic and social structure, unlike the theories of other political economists, which were concerned with explaining the Industrial Revolution.

These three scholars—Smith, Ricardo, and Marx—are considered the progenitors of modern economics; in due course their ideas were exported across the Atlantic and promoted in the United States.

The Industrial Revolution in the United States

The Industrial Revolution that began in the mid-19th century in the United States must have seemed to others to have come out of nowhere. Europe had been the undisputed economic and technological leader in the world until, suddenly, the United States appeared in the vanguard. By 1926, the United States was producing about 45% of the world's industrial output, including 80% of the world's automobiles and 50% of its steel, electricity, and crude oil. America's experience of the Industrial Revolution had a decisive effect on the role of human resources in the economy and on social conditions for the American family. The Industrial Revolution in the United States thus mirrored Europe, as production changed from the manufacture of goods in small workshops to making goods with machines in factories.

The Industrial Revolution in the United States placed the family squarely in the capitalist mode of production, a fact well documented by the stories of urban working-class families' struggles to survive the Industrial Revolution. Changes in social relationships in the workplace and in households as a result of the Industrial Revolution have been viewed as both progressive and antiprogressive. The limits of capital's extensive mode of consuming labor in the first phase of industrialization, it has been argued, created a false consciousness among urban working-class families. The forces inducing conversion to a more intensive regime of separate spheres between work and home in the latter half of the 19th century were crystallized. Changing forms of family occurred as a result of the Industrial Revolution, as modern industry created the social construction of the "male breadwinner wage."

Thus, the economic structure of modern industry led to significant changes for American families. Prior to the industrial revolution, families had been largely self-sufficient work units. Fathers and mothers worked side by side, and children joined in the work as soon as they were able. Almost all of the values and skills needed for life were learned in the family setting. A sense of self-worth came naturally as did a sense of one's place in society.

The Industrial Revolution and the growth of cities changed all that. Fathers left home to work for money wages, and real wages rose quickly. Many families left their small farms and moved to the city. Children became more of an economic liability and less of an economic asset as they became unable to contribute to family maintenance. During the Industrial Revolution, work changed from requiring physical strength to requiring the ability to manipulate factory machinery, and what adults did was separate from children. This prompted the social need to limit the size of the family during the early years of the 20th century. The modern image of the family consisting of mother at home, a father at work, and children playing at home was born during the Industrial Revolution. Some scholars see the current crisis in family life as a long-term effect of the Industrial Revolution, one that poses a serious challenge for the 21st century.

In the United States as elsewhere, the Industrial Revolution greatly enhanced the economic fortunes of the middle classes and brought economic and social improvement for many people owing to the increase in earned wages. The lower classes, however, gained far less economically and socially. As the nation advanced, it failed to build adequate support systems for families in which both parents were employed. Indeed, the United States has not put national policies in place to provide for children's needs, as many European countries have done. Much of the energy behind popular demands for political change arises from the perception that the socioeconomic system that resulted from the Industrial Revolution and its aftermath has expanded social inequalities. As some economists and sociologists have pointed out, economic power in the 21st century has remained concentrated in the hands of those who own and control the means of production.

Infinity

Infinity refers to that which has no end. Inherently filled with paradoxes and contradictions, it is a concept found in math, science, and philosophy, and it can refer to time, space, and numbers.

Mathematical Infinity

Infinite Sets

In mathematics, infinity is not a number itself but a construct to refer to a sequence of numbers with no ending. The common symbol for infinity, ∞, was introduced into mathematical literature by the English mathematician John Wallis in the 17th century. Positive integers are an example of a set of infinite numbers, because there is no last number. For any number that one can consider, there is always a higher one.

Nineteenth century mathematician Georg Cantor stated that a collection is infinite if some of the parts are as big as the whole. This can seem to create paradoxes. For example, if one has an infinite number of objects, he or she can add or remove objects from the group and still have the same quantity. In the above example, positive integers make up an infinite series, but so do a set of just positive *even* integers. The second set comprises only a part of the first set, which would appear to make it only half as large. But in both cases, a larger number always follows, so they are both infinite.

Aristotle described two ways of looking at an infinite series. In actual infinity, one conceives of the series as completed. In potential infinity the series is never completed, but it is considered infinite because a next item in the series is always possible.

Other Uses of Infinity in Mathematics

The concept of infinity was introduced into geometry in the 17th century by Gérard Desargues. He developed projective geometry, in which "infinity" is the point where two parallel lines meet, a concept that was already being used in art.

In the algebraic function $y = 1/x$, y approaches infinity as x approaches zero. The expression y could never actually be infinity, since x could never be zero, because an expression of division by zero has no meaning in algebra. However, the smaller that x gets, the more times it could be divided into 1.

Paradoxes of Infinity

The Greek philosopher Zeno of Elea wrote of the dichotomy paradox. In order to travel a certain distance, we would first need to travel half of the total distance. In turn, before we reach that point, we must first have gotten halfway there (1/4 of the total distance), and so on. The distance we would need to travel first becomes infinitely smaller, so that it is impossible even to get started—for every distance to travel, there is always a smaller distance to travel first. These circumstances obviously would not have the same result in a real-life occurrence. However, the paradox demonstrates the idea of a distance being infinitely divisible. In other words, there are an infinite number of fractions between zero and 1 (or any two numbers).

The same idea is demonstrated in Zeno's paradox of Achilles and the tortoise. In the story, Achilles, a swift runner, races the slow tortoise but allows him a head start of 100 feet. If we imagine that each racer is going at a constant speed (one fast, one slow), then after some period of time, Achilles would have reached 100 feet—the tortoise's starting point. But by that time, the tortoise would have advanced a further distance. By the time Achilles catches up to the new point, the tortoise would have gone still farther. Zeno states the paradox: Achilles would never catch up to the tortoise, because the more distance he travels, the further ahead the tortoise is. To catch up to the tortoise in the story, Achilles would need to complete an infinite number of actions. Aristotle responded to this paradox by using the ideas of actual and potential infinity. Like the dichotomy paradox, this paradox assumes an actual infinity of points between Achilles and the tortoise.

Neither of these paradoxes would happen in a real-life occurrence, because a person can travel a given distance without having to take account of each point between the start and finish. Therefore, the traveler would be able to reach the destination, and Achilles would catch up to (and surpass) the tortoise in a finite time.

Bertrand Russell described the Tristram Shandy paradox, which is based on the title character of the novel by Laurence Sterne. In the novel, Shandy attempts to write his autobiography but finds that it takes him 2 years to write about the first 2 days of his life. Shandy complained that he would never be able to complete the writing, because the more he wrote, the more material there would be to write about. Russell suggested that if Shandy lived for an infinite number of years, then every day of his life would eventually be written about.

The paradox lies in the fact that there would never come a day when Shandy could finish the book, because with each day of writing, he became a year farther away from his goal.

Infinity of Time

Time and the Universe

In some schools of thought, time is inextricably linked to the universe itself. Thus, many theories dealing with the infinity of time are actually referring to the infinity of the universe. Saint Augustine wrote that time exists only within the created universe, with God existing outside of time in the "eternal present." While science theorizes that the universe began with the big bang, we cannot know if time began at this point as well or if there was time before there was a universe. According to some theories, the universe will end with a big crunch, but again, it is unknown if time would end at that point as well. Richard Tolman, in his oscillatory universe theory, hypothesized that the universe is in an infinite cycle of big bangs followed by big crunches.

An Infinite Past

The possibilities of an infinite past or infinite future have been discussed by philosophers for millennia. In 1692, English theologian and scholar Richard Bentley rejected the idea of an infinite past while accepting the idea of an infinite future. He wrote that the revolution of the earth, occurring in the present, could continue into infinity, because the future was inexhaustible. However, an infinite number of revolutions in the past was not possible, because each revolution would have once been part of the present and therefore finite. Immanuel Kant also rejected an infinite past, saying that an infinity cannot be completed, and if the past were infinite, we would never have arrived at the present moment.

Modern Perspectives

Debate about various aspects of infinity has continued into the 20th and 21st centuries. Albert Einstein wrote that our universe was finite but had no boundaries. Physicist Stephen Hawking built upon this idea, proposing that time and space together were finite but boundless (similar to the surface of the earth) and therefore had no beginning.

Galileo stated that infinity, by its very nature, was incomprehensible to human minds. Nevertheless, it is likely that infinity, with its possibilities and paradoxes, will continue to be a source of theory and discussion.

Information

The theory of information is fundamental to a rational understanding of the temporal fabric of our world. The principal reason for this is that information and time cannot be separated reasonably—a fact that will become evident from a short consideration of how we know about time and information. Only if information produces effects on objects whose changes in time are measurable physically is there a chance to test hypotheses about information objectively. Time, again, is measurable by a physical system only on condition that this system has information about its internal changes. To measure time, information about change is necessary, and to measure information, change in time is necessary.

Motivated by concrete problems of empirical research and engineering, the theory of information is steadily developing into a coherent system of mathematical models describing the complex abstract structure of information. On the one hand, information is an entity difficult to grasp, because the interactions between its syntactic, semantic, and pragmatic components constitute a complex structure. On the other hand, information is something supposed to exist almost everywhere: Its abstract features are claimed to be discernible in the most different kinds of systems such as quantum entanglements, cells, humans, computers, and societies.

The need for a unified theory of information is, thus, felt at nearly all frontiers of science. Quantum physicists are discussing whether an interpretation of their experimental data in terms of information could resolve some of the paradoxes that haunt their understanding of the subatomic world. Cosmologists are calculating the information content of black holes. Geneticists are describing the hereditary substance as containing information that is decoded in cells by means of the genetic code. Evolutionary biologists are assuming that the most important steps in the history of life on earth consisted in establishing increasingly efficient ways of information processing. Neurophysiologists are talking about the brain as the most complex information processor known to us. Computer scientists are constructing and programming machines that process information more and more intelligently without being continuously assisted by humans. Communication engineers are building information networks that connect human brains to computers in a new kind of symbiosis. Economists are proposing mathematical theories of economic behavior based on the distribution of information among people who buy and sell goods in a market. Sociologists are characterizing developed countries as information societies in a globalized world.

If we do not want to get lost in the jungle of information concepts used in different sciences, and if we want to make the relation between time and information clear, we are well advised to orient ourselves with the help of a rough classification of the manifold aspects of information and to distinguish its syntactic, semantic, and pragmatic components. The scientific disciplines of syntax, semantics, and pragmatics are known to anyone who studies language or other sign systems. In short, *syntax* is the study of signs in their relation to other signs; *semantics* is the study of signs in relation to their conceptual and referential meaning; *pragmatics* is the study of signs in relation to the agents using them. That all three disciplines are also of utmost importance for an information theorist should not come as a surprise, because sign systems basically are means of transmitting information. Each sign is, as it were, a package of information: a syntactic unit that transports a meaning from a sender to a receiver.

This entry presents some fundamental characteristics of the syntactic components of information and reflects on the relation between syntactic and semantic features of information. The reason for restricting ourselves to these topics is that the general semantics and pragmatics of information still constitute a mostly uncharted continent. To explore it further, not only sophisticated mathematical models but also new concepts for analyzing the close relation between time and information will have to be developed.

Syntactic Features of Information in Shannon's Communication Theory

Syntactic features of information are described by a variety of mathematical models. The most important one resulted from Claude E. Shannon's understanding of communication as transmission of information. Shannon (1916–2001), researching on communication systems first as an engineer at the Bell Laboratories and then as a professor at the Massachusetts Institute of Technology, has rightly been called "the father of information theory." The scheme of a general communication system he introduced in his classic paper, *A Mathematical Theory of Communication* (1948), still is the basis for most research in information theory.

According to Shannon, a general communication system consists of five components: an information source, a transmitter, a channel, a receiver, and a destination. The information source generates a message that is to be transmitted over the channel to the destination. Then the transmitter encodes the message in a signal that is suited for being transmitted via the channel. In the channel, there normally exists a certain probability that noise distorts the signal. The receiver decodes the transmitted and possibly distorted signal. Finally, the message is delivered to the destination. This general communication system can easily be exemplified by telephony. A person (the information source) speaks into a telephone (the transmitter) that encodes sound waves in a sequence of analog or digital signals. These signals are transmitted via fiberglass cables, air, satellites, or other channels. The physical structure of the medium of transmission, atmospherics, defective electronic devices, jamming stations, and other noise sources might distort the signal. A telephone at the other end of the channel (the receiver) decodes the transmitted signals in sound waves that some person (the destination) can hear.

Shannon introduced the general communication system in order to solve two main problems of information transmission. First, how many signals do we minimally need on average to encode a message of given length generated by an information source? Second, how fast can we reliably transmit an encoded message over a noisy channel? Both problems ask for principal spatial and temporal limits of communication, or in other words, for minimum code lengths and maximum transmission rates. To answer these questions, Shannon defined an information-theoretical analogue to entropy, the statistical measure of disorder in a thermodynamic system.

Omitting formal technicalities, Shannon's crucial idea goes as follows. For any message that is generated by an information source, the information content of the message is equal to the amount of uncertainty that the destination of the message loses on its receipt. The less probable the receipt of a message is, the more information it carries to the destination. Shannon's measure of the entropy of an information source, in short: Shannon entropy quantifies the average information content of a message generated by an information source.

Shannon's noiseless, or source, coding theorem shows that the entropy of an information source provides us with a lower boundary on the average length of signals that encode messages of the information source and are transmitted over a noiseless channel. If the length of these messages goes to infinity, the minimum expected signal length per message symbol goes to the entropy of the information source. Shannon entropy defines, thus, in terms of signal length, what a sender can optimally achieve in encoding messages.

In his noisy, or channel, coding theorem, Shannon proves the counterintuitive result that messages can always be sent with arbitrarily low, and even zero, error probability over a noisy channel—on condition that the rate (measured in information units per channel use) at which the message is transmitted does not exceed an upper limit specific to the particular channel. This upper limit is called *channel capacity* and can be quantified by an ingenious use of Shannon entropy. If we subtract from the entropy of the information source the conditional entropy of the information source given the messages that are received by the destination, we get the mutual information of the information source and the destination. *Mutual information* measures how much the uncertainty about which message has been generated by the information source is reduced when we know the message the destination has received. If the channel is noiseless, its capacity is equal to the Shannon entropy of the information source. The noisier the channel is, the more signals we must transmit additionally in order to correct the transmission errors. The maximum mutual information of an information source and a destination equals the capacity of the channel that connects both. That a sender who wants to transmit a message reliably tries to achieve channel capacity, regardless of how noisy the channel is, seems to be a vain endeavor, because any correction signal is subjected to distortion, too. Yet Shannon could show that for any noisy channel, there do exist codes by means of which a sender can transmit messages with arbitrarily small error at rates not above channel capacity—alas, he did not find a general procedure by which we could construct such codes, and up to now no information theorist has been able to perform this feat.

Shannon's coding theorems prove, with mathematical exactness, principal physical limits of information transmission. His channel coding theorem shows that if we want to reliably transmit a message over a noisy channel—and any realistic channel is noisy—we must respect the channel capacity as an upper limit on the transmission rate of our message. If we want to be sure that another person receives our message in its original form, we must take the properties of the medium of transmission into account and make the encoding of the message as redundant as necessary. To make an encoding redundant means to make it longer than required by the noiseless coding theorem. It means that we need more time to transmit a message over a noisy channel than over a noiseless one. Shannon's information theory implies, thus, an economics of information transmission: Given the goal of reliable information transmission and knowing the noise in a channel, we must respect a spatial lower limit on the length of encodings and a temporal upper limit on their transmission rate.

Shannon entropy measures only a syntactic property of information, more precisely: a mathematical property of statistical distributions of messages. Its definition does not explicitly involve semantic or pragmatic aspects of information. Whether a transmitted message is completely nonsensical or very meaningful for its destination, Shannon entropy takes into account just the probability that a message is generated by an information source. Since Shannon published his mathematical theory of communication, further statistical measures of syntactic aspects of information have been defined. For example, the theory of *identification entropy,* developed by the German mathematicians Rudolf Ahlswede and Gunter Dueck at the end of the 1980s, refers to Shannon's general communication system yet introduces a decisive pragmatic difference as regards the purpose of communication. In Ahlswede and Dueck's scenario, the information source and the destination are not interested in the reliable transmission of all messages that the information source can generate. The destination just wants to be sure as fast as possible that one particular message has been sent, which might have been encoded in different signals by the sender. It is the situation of someone who has bet money on a horse and only wants to know exactly whether this horse has won the race. Such a relaxation in the goal of communication allows an enormous increase in the speed of information transmission.

Semantic Features of Information in Shannon's Communication Theory

The semantic and pragmatic features of information are much more difficult to formalize than its syntactic features. Some approaches to semantic aspects of information try, therefore, first to identify syntactic properties of signals that may be correlated to the fact that these signals have a meaning for both the information source and the destination. When we speak about meaning, sense, reference, and other semantic concepts in an information-theoretical context, we do not suppose that information sources and destinations have complex psychological qualities like those of human beings. Access to semantic aspects of information is, thus, not restricted to self-reflective agents who associate, with signs, mental representations as designations and who refer consciously to objects in the real world as denotations. In this sense, "the semantic component of information" just means that at least a set of messages and a set of signals are interrelated by means of a convention.

A code, as a system of conventional rules that allow encoding and decoding, is the minimum semantic structure *par excellence.* It is normally not possible to infer which message is related to which signal, and vice versa, if we know only the elements of both sets (i.e., the messages and the signals), and the natural laws that constrain the encoding of messages in signals and the decoding of signals in messages. Thus, the most characteristic feature of the semantics of information is the conventional nature, or contingency, of the relation between messages and signals.

From this perspective, Shannon's theory of communication as information transmission does say a lot about semantics implicitly, because it is also a theory of the encoding of messages in signals and the decoding of signals in messages. Shannon's coding theorems express information-theoretical limits on the syntax of signals if the latter semantically represent messages under pragmatic constraints on the compressibility of encodings and on the reliability of transmissions.

Let us now focus our discussion on the channel coding theorem and the measure of mutual information. The higher the channel capacity—that is, the higher the maximum mutual information of an information source and a destination—the more is known about the statistical properties of the information source given the destination, and vice versa. We can express, for each channel, the information transmission distance between a given information source and a given destination in terms of time minimally needed by the fastest receiver for interpreting transmitted signals correctly as syntactic units that represent other syntactic units, namely messages. The noisier the channel between sender and receiver is, the less certain the semantic relation between a received signal and a transmitted message is for the receiver. Because the most general pragmatic function of communication is, for Shannon, the loss of uncertainty, the gain of uncertainty due to noisy channels must be counteracted by the use of longer signals. Then the actual rate of information transmission over the channel decreases and the transmission time increases. The more effort has to go into making a signal a reliable representation of a message, the longer the receiver needs to infer the transmitted message from a received signal.

Conclusion

We started our investigation into the relation of time and information by observing two very general facts: To measure time, information about change is necessary; and to measure information, change in time is necessary. We ended up describing an important example of the latter fact in semantics: The less certain the semantic content of a signal is, the more time is required to receive further signals needed for getting to know the message. Shannon's theory of communication contains, thus, a quantitative insight into the context dependence of information: Interpreting signals is a process that must obey temporal constraints depending on the media used for information transmission. In-depth analysis of the semantic, and also the pragmatic, features of information will arguably need more insight into the interdependence of time and information.

Intuition

Intuition is a concept with a number of meanings. It derives from the Latin *in-tueri:* knowing from within, that is, by contemplation. Intuition is a mode of perceiving objects, concepts, and ideas through direct apperception, as when people refer to having had an insight or illumination. In modern psychological approaches to various processes of judgment, intuition, in contrast with analytical thought, is described as a fast and instant thought process that does not demand mental effort, is not necessarily conscious, and allows neither description nor explanation. One illustration is constituted by heuristic processes, which are a type of unexplained rules of thumb that allow us to make various judgments, including perceptual judgments, rapidly. Another common description of intuition is "just having a hunch."

Intuition and time are related in both directions: On one hand, we can examine the role of intuition in the processes that lead to time perception and perception of duration, while on the other, we can observe the role of time in intuitive processes themselves.

Time is a key dimension to which every living creature must relate in order to adapt to its environment. Nevertheless, in the absence of any specifically defined perceptual apparatus for duration perception, on one hand, and, on the other, of any specific stimulus that represents temporal duration, the question arises of how time apperception occurs. Though this question is relevant in relation to any living creature, it is especially so to human beings due to their awareness of time. This is why philosophers have always wondered about the nature of time and about how the sense and consciousness of time and duration emerge.

An early example of this can be found in Saint Augustine of Hippo (354–430), who deals with the question of time in the sixth book of his *Confessions*. He argues that, when not asked about the nature of time, he knew the nature of time; however, when asked to explain, he was unable to explain. His text suggests that time is a type of primary experience that we cannot explain. That is to say, time is not experienced as the product of higher-order cognitive activity. Indeed, some major philosophers share a notion of time as a primary intuitive concept.

Immanuel Kant (1724–1804) held that time and space are two major intuitions of the human mind. He rejected doctrines like Gottfried Leibniz's, according to which experience is characterized by an inherent rationality. Kant argued that time and space are a priori categories necessary for human experience to occur. As such, he thought time and space to be enabling conditions of the human mode of experience. Time is not a real feature of things-in-themselves but rather a structure of the knowing mind.

Henri Bergson (1859–1941) rejected Kantian idealism but still associated time with intuition. He distinguished between an intuitive and an analytical mode of thinking. Intuition, for Bergson, yields metaphysical knowledge of reality as time, change, and creative evolution, which is certain knowledge. Reason, on the other hand, does not render absolute knowledge about reality but only relative knowledge about the material objects of science and experience. If reality is in flux—that is, not static—then for Bergson it is intuition that gives us this awareness of time and change as creative evolution.

Modern psychological theories have been dealing with the question of whether intuition forms the substrate of perception on the whole and of time perception in particular. But while most of them consider sensory input from the external environment a key component in a person's image of the world, some acknowledge that this sensory component is not sufficient. One example is the *constructive perception* approach (e.g., that of Jerome Bruner). *Gestalt psychology* (J. P. Kotter, Kurt Koffka, Max Wertheimer) holds that perception does not consist of a direct reflection of physical features of external reality. The perceptual system imposes organizing principles (*gestalt rules*) on the incoming stimuli, and these eventually determine the resulting image in the human brain. These organizing principles could be considered a priori, intuitive rules.

Developmental cognitive research, to which Jean Piaget (1896—1980) was a crucial contributor, has dedicated much attention to the development of the ability to grasp time in its various respects, e.g., the ability to understand the sequential nature of the time in which external phenomena occur. According to Piaget's findings, the ability to grasp time evolves in stages and gradually. A case in point is the development of the ability to integrate information according to the sequence and order in time of phenomena or actions. Children below age 12, it was found, are affected by intuitive thinking when making judgments about time, and this causes misperceptions. Abstract thought and logical reasoning evolve only in the formal operations stage, between ages 12 and 16. The ability to fully grasp time concepts matures only at a relatively late stage, and this testifies to the complexity of time perception. On the basis of this research, Piaget concluded that human understanding of time is not intuitive and depends on the acquisition of complex mental abilities.

Contemporary models of psychological time, too, consider the experience of time as the product of a cognitive process based on elaboration and integration of various types of information. This, it should be noted, does not necessarily clash with the Kantian approach: It could be that the concept of time as such—rather than the experience of duration—is intuitive and a priori.

Modern psychological approaches to cognitive processes and judgment consider intuition as a mode of thinking with unique features, which is unlike analytical thinking. This distinction refers to time as one of its parameters. First, intuitive thinking is very rapid, in contrast to analytical thinking. Second, intuitive thinking relies on past experience and on tacit knowledge (H. A. Simon), that is, on accumulated information that has been encoded in the memory over time.

Daniel Kahneman and Shane Frederick (2002) suggested that judgment can be achieved in two manners. The first is by means of a rapid intuitive, associative, and automatic process that demands no mental effort—this is also known as System 1. Alternatively it can result from a slower process that requires mental effort and that is controlled by rules and laws: System 2. Intuitive errors, accordingly, occur under two conditions: System 1 errs (usually due to applying past experience that is not relevant to the judgment in question) while System 2 fails to get activated in order to correct the error. Intuitive thinking, it must be noted, can produce effective and adaptive judgments if it is based on relevant experience, as happens in the case of expertise in the field of judgment. It is not easy to remove bias in the case of intuitive errors. Many perceptual illusions are the result of the activation of intuitive heuristics: Mere awareness of this does not suffice to avoid the perceptual illusion. Time illusions, too, which are expressed in erroneous experience of the clock duration of various events, are the result of heuristic intuitive thinking. Thus, for instance, in the case of the “filled time illusion,” a time interval “filled” with stimuli and events is perceived as longer than a time interval identical in duration but “empty” in terms of stimuli and events (see also Time, Illusion of).

In part, time affects heuristic thinking as it does due to organizational processes in the memory that occur involuntarily in the course of time. As a result, a person is not always aware of the correct order of events in objective time, so that it may occur that later information may be perceived as—or combined with—earlier information. This may be reflected in intuitive biases like false memories or hindsight bias.

Often errors in eyewitness evidence are actually in part the result of such processes. And so we observe that the very dependency of intuition on the accumulation over time of information in the memory may cause intuitive bias regarding the dimension of time itself.

Islam

The religion of Islam originated in 622 CE, inspired and guided by the teachings of Muhammad ibn Abdullah, who lived in Mecca, Arabia, and who (in the Islamic belief tradition) received revealed truths directly from God and recorded them in the holy text called the Qur’an. As a religion, Islam has its roots in the same Middle Eastern monotheistic faith as Judaism and Christianity, and they share many of the same beliefs, practices, and sacred texts. Followers of all of these Abrahamic religions believe themselves to be descended down through time from the first man (Adam) and to have been chosen as God’s special people through a covenant made between God and the Hebrew patriarch Abraham in about 1800 BCE. However, while Judaism teaches that the Messiah has not yet been born, and Christians believe that Jesus Christ was the divine Messiah, followers of Islam believe that Christ and Muhammad were both prophets of God in the tradition of Abraham, Moses, Samuel, and others but were not themselves divine.

Muslims believe that Muhammad was the last messenger or prophet sent by God to restore his people to the original, uncorrupted version of the Abrahamic faith. Muslims (“those who submit to God”) therefore seek to return to the earliest and purest forms of worshipping God through the constant practice of the five pillars of Islam: professing faith, fasting, prayer, alms giving, and making the *hajj* pilgrimage to Mecca. The word *Islam* means “submission,” and Muslims seek to demonstrate their obedience to God’s will in all aspects of daily living, holding the teachings of the Qur’an to be a literal and uncorrupted version of God’s laws, in contrast to the practices and texts of Judaism and Christianity, which have been distorted and corrupted by the long passage of time since the covenant was made between Abraham and God. In contrast to what they believe about the Qur'an, Muslims consider all earlier holy texts of the Abrahamic tradition (the Old and New Testaments) to be only partially "revealed" versions of God's will, because they were not recorded directly by the Hebrew and Christian prophets themselves but were embellished and altered by the followers and descendants of those prophets.

Time is also an important criterion in determining the *Sunni* (the "trodden path") practices that Muslims use to regulate religious practice and beliefs: *Sunnah* are defined as those religious actions and practices that Muhammad introduced during the 23 years of his ministry and that were subsequently passed down as tradition to subsequent generations by his closest companions. Adhering to tradition, by ensuring that religious holy days are observed at the correct times and for the correct durations of time, is therefore an extremely important aspect of Islamic culture. And, the Islamic world has evolved intricate and highly formalized ways of marking the passage of time and the timing of religious observances and holy days or months through use of a lunisolar calendar.

Origins of Life

The Islamic version of the origins of life and humanity has many parallels with Judaic and Christian beliefs. For Muslims, the creation of the universe is proof of the all-encompassing and absolute power of Allah (God). Allah is the beginning and end of all things, and the universe itself is an expression of his will, subject to his laws. For Muslims, the creation story derives from the Qur'an, which describes the division of the heavens and earth by Allah (God) from one solid mass into their present states over six long stages of time (not literal days as in the Judaic or Christian versions of the creation myth). Allah next created all of the living creatures and vegetation that inhabit the earth and sky, as well as the angels and heavenly bodies. Last, Allah used clay, earth, sand, and water to make and breathe life into the first man (Adam).

By breathing his own spirit into Adam, God distinguished him from the animals and endowed him with the ability to think and freely choose to submit to Allah or not, as well as to use his intelligence to seek to understand the workings of God in the rest of Creation. After Allah took Adam to live with him in paradise, Allah also created the first woman (Eve, or Haw) from Adam's side, and placed the two humans in a beautiful garden in paradise, forbidding them to eat the fruit of a certain tree. Ibis, an evil jinn (a disobedient angel, or Satan), tempted Adam and Eve to disobey God and eat the fruit of that tree. When they did, God cast them out of paradise and sent them to live on earth. In Islamic belief, all human beings are descended from Adam and Eve.

End of Time

As with the other Abrahamic religions, Islam depicts the end of time as a period of great disruption and trouble. This period will directly precede the Second Coming of the Messiah, who will bring an end to evil and suffering and will establish a new era of the kingdom of God. The Qur'an does not provide specific details about the end of time (Allah will not reveal these until that time arrives), but it does describe many signs that will signal its imminent arrival. The signs associated with the end of time will include such dramatic environmental events as drought, flood, the falling of the stars, and the cleaving of the heavens. As well, the earth will be purified of nonbelievers, either through mass conversion or by death. Most of humanity will have begun to worship the *Dajjal* or Antichrist, who opposes God's law and is aided by two leaders (Gog and Magog) who head nations opposed to God. The Dajjal will be ultimately defeated by the *Mahdi* ("the guided one"), a great leader descended from Muhammad who will become the final Muslim caliph. He will unify all of the various sects within Islam and will lead Muslims to a period of great prosperity and equality.

The prophet Jesus Christ will return to earth to aid the Mahdi in establishing Islam as the one true religion and to help defeat all of the unbelievers. He will then live on for 44 years until he dies and is buried next to the prophet Muhammad. Christ's death and burial will be followed by the resurrection of all humankind in preparation for the final judgment day. The sequence of events leading up to the judgment day will include a first trumpet blast, which will crush the mountains and kill all living creatures on earth (including the angels); a second trumpet blast, which will mark the resurrection of all humans; the descent of Allah to earth in order to pass judgment on all humans; the passing of thousands of years while humanity awaits judgment; and the final judgment or division by Allah of humankind according to whether or not their good deeds have outweighed their bad deeds during their lifetimes. Those who have submitted to Allah's will and followed his commands will enter paradise and then be placed to the right of his throne; those who rebelled against Allah by practicing evil ways will be placed to the left of his throne and condemned to live in hell for all time.

Jainism

Jainism is a non-Brahmanical philosophical tradition of India. Enriched by the deep insights of 24 spiritual gurus or *tirthankaras,* from Risabha (the first) to Mahavira (the last), Jainism has its own distinctive flavor that distinguishes this philosophy from others. To understand the concept of time in Jainism, it is necessary to have an overall idea of the metaphysical system of the Jainas. Jainas believe in a many-sided view of reality, known as *anekantavada,* or the theory of pluralism. This concept of reality can accommodate identity and difference, permanence and change. There are two main important terms in Jaina philosophy, *dravya* and *astikaya,* which pervade Jaina writings. The concept of *kala* (time) is to be understood in terms of these two concepts.

Umasvati, a famous Jaina philosopher, defines *dravya* or substance as that which possesses qualities and modes. Substance is always characterized by qualities and modes. Jainism offers six substances as ultimately real, and time is one among them. They are *jiva* (the soul), *pudgala* (the matter), *dharma* (the principle of motion), *adharma* (the principal of rest), *akasa* (space) and *kala* (time).

Amongst the six substances, five are known as *astikaya,* a term which, negatively speaking, helps to understand the concept of time. In the *Dravya-Samgraha,* a famous book of the Jainas written by Nemichandra, the term *astikaya* is explained in the following way: This term consists of two parts, *asti,* meaning "to exist" and *kaya,* meaning "body." Therefore this term refers to those five substances that exist and occupy space. The term *kaya* also technically is to be understood as consisting of many indivisible particles (*pradesa*). So, five out of the six substances apart from time can be characterized as astikayas. This notion of indivisible particles points to the fact that the Jainas believe in the general atomic conception of the universe. The five substances are called astikaya (extended) because the particles of which they are made are not separate. This is also the reason why time is not classified as an extended substance, even though it has existence.

According to Jaina philosophy, time is real, as it possesses origination, decay, and permanence, the characteristics of all real things. Time is as real as the five others, as it is the accompanying cause or condition of the modification of substances. This reality of things is explained by the Jaina philosophers by recognizing the two aspects of things, *parjaya* (the mode) and *dravya* (the substance). The former is the series of temporary modes with coming and going, and the latter is the core thing that remains constant. Time as a real substance possesses all these states. The above can be explained by taking an example from our everyday life. When a man clenches his fingers into a fist, then this phenomenon—clenching of the fingers—occurs (origination), and the previous state of the fingers necessarily is at end (decay), yet so far as the fingers are concerned, they continue to be substantially the same (permanence).

In the famous Jaina text entitled *Pancastikayasara,* the atomic conception of time is discussed. The

This 15th-century Jain temple at Ranakpur represents a culmination of Jaina temple building in western India.

characteristics of time atoms are such that each atom is distinct and can never be mixed with other time atoms. This is the reason for advocating the theory that time has one *pradesa* only, or in other words, the time atoms can never be combined. And this also leads to the point that the time atoms can only constitute a unidimensional series that is unilateral. In Jaina terminology, this is known as *urdha-pracaya* (unilateral) as opposed to the *tiryak-pracaya*—a multidimensional series or horizontal extension. All other substances except time possess extensions in both these dimensions. As kala (time) consists of infinite *samaya* (instants), it possesses only unilateral extension. This unilateral extension of kala points to the fact that the world is constantly progressing with the help of time.

The Jainas held that there are two kinds of kala, *vyavahara kala* (conventional time) and *niscayakala* (transcendental time). Vyavahara kala is also known as samaya in Jaina philosophy. In our daily life we use the concepts of moments, hours, and days to indicate the beginning and end of a particular event. This conventional or practical time is indicated by modification, activity, distance, and proximity. The Jainas describe modification as the self-variation in a thing without a change in its substance. Activity is caused by the movement of a body. Distance and proximity are to be understood here in relation to time. In our everyday life we label a thing as new or old by observing its state of modification. On watching the sunrise in the east, we say we have the daybreak, and so we gather the ideas of midday, evening, and night by observing the movements of the heavenly bodies. A thing under actual observation is said to be proximate in time, otherwise it is distant in time. In this way, the external objects indicate and refer to the conventional or empirical time denoted by moments, hours, and days, as we call them.

In the Jaina literature, *pancatikaya-sara,* the conventional or empirical time periods, are discussed elaborately. The minutest unit of kala is *samaya.* This unit is defined as a period of time taken by an *anu* (atom) in traversing to its consecutive anu. *Vyavahara kala,* or conventional time, consists of infinite samaya. The time undertaken by an adult person in inhaling and exhaling is termed a *prana.* Seven pranas make one *stoka.* Seven stokas compose one *lava.* Thirty-eight and one-half lavas form one *nali.* Then comes *muhurta,* which is equal to two nalis. Thirty muhurtas form one *divaratra* (day and night). Fifteen divaratras form one *paksa.* One month comprises two paksas. Two months equal a *ritu* (season). Three ritus make one *ayana.* A year is formed by two ayanas. These divisions and subdivisions of time are linked to the different units of measurement pertaining to *vyavahara-kala* or conventional time.

The above divisions are dependent on some external factors, such as the motions of the heavenly bodies. But in addition to the motions of the heavenly bodies, vyavahara kala or conventional time is dependent on niscayakala, or transcendental time, for the determination of its measure. This niscayakala is variously designated as *paramarthkala* or *dravyakala. Vartana,* or continuance, is the main characteristic of niscayakala. Brahmadeva, a commentator on Jainism, holds that vartana is the accompanying cause of the modifications of things, like the stone beneath a potter's wheel or like fire in the matter of studying in winter. This vartana is the characteristic of real time. The stone underneath the potter's wheel does not directly impart motion to the wheel, but still the stone is indispensable in the matter of the movement of the wheel. Similarly, fire is not directly responsible for one's study, but study is impossible in winter without fire for heat and light. The case of time is comparable.

Therefore the changes that can be observed in things point to something more than those changes and the changing things. Every change is accompanied by a definite point of time, called samaya, or conventional time, while the continuing reality underlying this conventional time is the dravyakala, or transcendental time. The transcendental time is conceived as having both a beginning and an end. This point brings an important feature of the Jaina understanding of time. The samaya, or instants arranged unilaterally, are conceived of as permanent—beginningless and endless. This is indicative of the fact that the transcendental time can never be made an object of sense perception. But one can arrive at knowledge by inference. Another characteristic is that time is *amurta* or formless; in this respect it is similar to the concept of soul. Time or kala is described as *niskriya,* or devoid of activity, and it is different from soul, which is *sakriya* or active.

The Jaina conception of transcendental time is to be contrasted to the idea of time as appearance. In fact the concept of time plays a very important role in the pluralistic metaphysics of the Jaina system. Nothing can be conceived in this universe without time.

Jainism with its realistic viewpoint of thinking accepts the reality of change, which in turn indicates the reality of time. It is not possible to deny the reality of time, as every change involving birth, growth, and decay happens within the framework of time.

Thus time is confined within the limits of *lokakasa,* or the space that is occupied by other substances; the *aloka,* which is beyond this, has not time within it. But as aloka is a substance, it must have modifications also. Now how are these modifications possible in the aloka, signifying void which has no time within it? This point is stated in the following way. Aloka, although it is beyond the loka, is still a part of the akasa, or space. Time being within the akasa, it brings about modifications in any part of it, just as a pleasant object coming in contact with a particular part of a body causes pleasant feeling all over the body, or a potter's stick moves the whole wheel by striking at a particular point of the pot. Innumerable and partless atoms of time fill the lokakasa. In Alokakasa there is absence of matter, and so there is absence of *kalanus,* or instants.

Anu is the smallest part of a substance, and when these anus are combined inseparably, the substance constituted of them is an extended substance. The five substances—jiva, pudgala, akasa, dharma, and adharma, are extended substances, because their smallest constituents are mixed together, and they remain inseparably combined with one another. But the case is different with time. Time has also minute kalanus, or instants, but these anus or ultimate particles are not capable of mixing up with one another. Therefore, these ultimate particles remain always separate. It is for this reason that Jaina thinkers compare time substance with a heap of jewels. The jewels embedded in a garland remain separate; similarly these anus do not form a kaya; that is, they do not aggregate as the other five substances do. In addition, each kalanu occupies only one pradesa , or space point. Therefore, it does not possess an aggregate or volume space point comparable to that portion of space that is obstructed by an anu or atom. These time atoms are imperceptible, formless, and inactive. Thus they have no extension, but they possess existence.

There is again another principle of classification, on the basis of which substances are classified as conscious or unconscious. Following this line, jiva alone is singled out as conscious, and all other substances, including time, are labeled as insentient.

In conclusion, it may be pointed out that the Jainas make change the essential character of all reality, which is intelligible only in terms of time. Jaina thought, with its law of pluralism accompanied by time as a constant variable, stands unique among the philosophical traditions of India.

JANUS

In Roman mythology, Janus was the god of doorways and of transitions in time. He was depicted as a double-faced head with the two faces looking in opposite directions. As the god of transitions, Janus was deeply associated with the notion of time.

Janus was one of the most ancient gods worshipped by the Romans. Unlike many other Roman gods, Janus has no Greek counterpart. The Romans invoked Janus at the beginning of each month, as well as at the new year. They prayed to Janus during important events such as birth, marriage, and harvest time. To the Romans, Janus signified transitions such as from primitive society to civilization, childhood to adulthood, and especially from war to peace and vice versa. The Romans built numerous temples in honor of Janus, and the name January for the 1st month of the year is a modern vestige of the deity.

As the god of beginnings, the Romans believed that Janus predated even Jupiter, the primary Roman god. According to tradition, Janus was the first king of Latium. His rule witnessed a golden age in which laws, coinage, and agriculture were introduced. The Romans believed that Janus had protected Rome from the legendary attack by the Sabines. In memory of this protection, the Romans left the gates of Janus's temples open when Rome was at war and closed them during times of peace. In addition to temples, Rome also had many gateways called *jani* (the plural form of *janus*) which often bore the symbol of Janus. The most important janus was the Janus Geminus located in Rome. It had a gateway at each end through which the Roman legions would parade before departing for war. The coins of the Roman Republic also carried the double-faced image of Janus. The Roman Empire later often depicted Janus with four faces looking in opposite directions, known as Janus quadifrons. Two of these faces were often bearded and the others shaven.

Janus was known as the inventor of religion, festivals, temples, and coins. The Romans held him in very high esteem as the custodian of the universe. In this role, he transcended many other gods in importance. Janus was present in all aspects of time: beginnings and endings, sunrise and sunset, the progression of life, and during rites of passage. He was invoked on a wide variety of important occasions in Roman cultural life.

In the Roman religion, Janus was believed to have come from Thessaly in Greece. He was invited to rule Latium with Camese. The two became the parents of the god Tiberinus, who was the Roman river god. The Tiber River in Rome is his namesake. Janus was also the father of Fontus, the Roman god of springs. Worship of the god Janus in effect ceased with the decline of the Roman religion. Janus is often cited in popular culture in connection with personalities or ideas that have two opposing sides.

JASPERS, KARL (1883–1969)

Karl Theodor Jaspers was a German existential philosopher whose initial profession had been psychiatry. In later life he attained an international reputation owing to his highly publicized statements as a political philosopher in postwar Germany and received several honorary doctorates and prestigious awards honoring his philosophical work for peace, freedom, and humanity.

Jaspers was born into a middle-class family in Oldenburg, northern Germany, on February 23, 1883. The liberal democratic mindset in his family deeply shaped his way of thinking. Jaspers first studied law, but partly owing to pulmonary disease contracted in his youth, he switched to the study of medicine. Due to his illness Jaspers was forced to live a calm and retiring life. Notwithstanding, he passed his exams in Heidelberg with distinction. In 1910 he married the nurse Gertrud Mayer, daughter of a Jewish merchant and sister of his fellow student Ernst Mayer.

Jaspers received his medical degree in 1908. He obtained his second doctorate from the philosophy faculty of Heidelberg University for his book *General Psychopathology,* still considered an important psychological work today. Beginning around 1910 Jaspers gradually had moved toward philosophy—mainly inspired by his readings of Baruch Spinoza, Immanuel Kant, Georg W. F. Hegel, Friedrich Nietzsche, and Søren Kierkegaard. His first predominantly philosophical book was *Psychology of World Views* (1919). By 1922 he had became full professor of philosophy in Heidelberg University.

In 1909 Jaspers made the acquaintance of Max Weber, one of the most important liberals, economists, and sociologists of prewar Germany. Weber was to play a guiding role in Jaspers's personal and academic development. During the same period Jaspers also met Ernst Bloch, Georg Lukács, Friedrich Naumann, and Georg Simmel.

Jaspers dissociated from the neo-Kantian philosophy that prevailed at this time and was one the first researchers who fought with insistence for a widening of the scope of philosophical sciences. Jaspers's main work is chastely titled *Philosophy* (1932) (*Philosophical World Orientation, The Illumination of Existence, Metaphysics*). Some further prewar works are *Man in the Modern Age* (1931), *Reason and Existence* (1935), and *Philosophy of Existence* (1938). Jaspers investigated the influences of borderline situations on the human being's attitudes and described a transcendental theory of the encompassing (*das Umgreifende*). Jaspers's attitude toward religion, however, was critical, and he did not consider it essential to philosophy.

Jaspers became deeply involved in the history of philosophy, which he understood as a facet of existential philosophy. He was among the first to think of history beyond the notion of a path of time or a path of ideas. Thus, when considering the heritage of the great philosophers, he replaces the link through time with the link through reason. One could say Jaspers widened the dimensions of history and time by ignoring their strict chronological order and interpretation.

Jaspers also dealt with Friedrich Nietzsche's thoughts about the eternal return or recurrence of time and the necessary overcoming of weakness and nihilism through such recurrence. Jaspers esteemed Nietzsche's work, although he disagreed with some parts of Nietzsche's legacy, particularly in Nietzsche's interpretations of the existence and role of transcendence. Furthermore, Jaspers was opposed to any thinking of the concept of the superior man.

Another outstanding person in his life was Martin Heidegger, with whom he shared an intense discourse. Nonetheless they quite frankly took very opposite philosophical positions. Jointly they are considered the most important representatives of German existential philosophy—clearly demarcated from Jean-Paul Sartre's existentialism. Their relationship abruptly ended the day Heidegger declared his accordance with the aims of Hitler. More satisfying was Jaspers's lifelong friendship with his former student, the political philosopher Hannah Arendt.

As a consequence of Jaspers's marriage to a Jewish woman and his declining to collaborate with the Nazi regime, he was subjected to certain restrictions, including the prohibition to teach and to publish. After the end of the war, however, with his reputation intact, he was among the well-regarded academics who helped to refound Heidelberg University, but in 1948 he chose to relocate to the University of Basel in Switzerland out of his dissatisfaction with the political and academic developments in postwar Germany.

Induced by his experiences during the Nazi tyranny, Jaspers had become an increasingly politically thinking person and fought against the quick rehabilitation of former Nazi collaborators like Heidegger. His well-known and controversial book

The Question of German Guilt appeared shortly after the war's end (1946). Jaspers assumed the role of a strong advocate for freedom and purer democracy. Some explicitly humanistic works, such as *The Atom Bomb and the Future of Mankind* (1961), followed. At this stage he pronounced the importance of an enlightened and educated bourgeoisie to the stability of democratically ruled societies.

Jaspers's circumscribed influence in modern philosophical theory, especially outside the German sphere, is partly due to the fact that more famous philosophers such as Heidegger and Theodor W. Adorno did not take issue with the greater part of his perceptions and ideas.

Karl Jaspers became a Swiss citizen in 1967. He died in Basel on February 26, 1969.

Josephus, Flavius (27–100 CE)

Flavius Josephus, a Jewish native of Jerusalem and later a Roman citizen, achieved lasting significance for his writings about Judaism and the Roman Empire (*The Jewish War, Antiquities of the Jews, Against Apion,* and *The Life of Josephus*). His own life and writings illustrate the 1st century clash of the Jewish and Greco-Roman worlds.

Although his historical works follow the methods of Greek historians like Thucydides, Josephus communicated the Jewish tradition of ancient history and the beginnings of time to the Greco-Roman world. As with Jewish histories in general, his observations of the passage of history emphasize a linear progression of connected events driven by divine providence. Though Josephus showed great interest in the accurate record of factual history, his ordering of events focused on the quality and readability of the story, often to the sacrifice of exact chronology.

Born to an aristocratic family within the Jewish priesthood, Josephus rose to prominence as a Pharisee and political leader in Judea, later receiving a military command during the Judean revolt. Josephus had been convinced of Rome's glory and power since he visited the empire's capital at age 26, and his own writings indicate that he felt neither convicted about the cause for revolt nor confident of any sort of victory for the Jews. Josephus was defeated and captured by the Romans at Jotapata in 67 CE, but he quickly made a powerful acquaintance with Emperor-to-be Vespasian by predicting his rise to power. Vespasian later secured Josephus's freedom and his Roman citizenship and provided for him in Rome with a residence and pension. Once he was in Rome, Josephus began his writing. Little else is known about the latter part of his life.

Major Works

In Rome, Josephus wrote *The Jewish War,* a commissioned account of the Judean revolt and the destruction of Jerusalem, which received imperial endorsement from Vespasian. For this task Josephus drew upon his own experiences in the war, Roman military records, and his many contacts. Josephus was politically sensitive in his handling of the conflict, generally pointing all blame toward the Judeans who had stirred up the revolt.

In his next undertaking, *Antiquities of the Jews,* Josephus composed his own version of Jewish history for explanation to the Greco-Roman world, covering a span of some 5,000 years. As an appendix to this account, he attached *The Life of Josephus,* a short autobiography that focused on his ambiguous role in the Judean revolt. *Antiquities* was based on the Hebrew scriptures as well as other rabbinic sources and traditions, but it also contains interpretations and inferences that were uniquely his. When dating events, he often used Jewish reckoning alongside that of other civilizations such as Egypt or Rome. As in *Genesis,* in *Antiquities,* time was said to begin with the 7-day divine Creation of the world, which became the model for a 7-day week. Josephus also recorded the origins of the feasts and celebrations that make up the Jewish year.

In his last work, *Against Apion,* Josephus defended his own accounts of Jewish history and offered an apology for the Jewish religion. Against Roman accusations that Judaism was a young and unimportant religion, Josephus argued that Judaism was in fact quite ancient and possessed a rich antiquity equal to that of the Greeks and Romans. In this work, Josephus sharply criticizes Greek histories initially but then uses them to help validate many aspects of Jewish history. Throughout his writing he confirmed his belief that God guided the events of history and that all things happened at the time appointed them by God.

Joyce, James (1882–1941)

James Joyce, widely regarded as the most important novelist of the 20th century, was born in Dublin to a family of modest means and was educated at Belvedere College, Dublin. He began his writing career within the then-dominant mode of literary naturalism but soon outgrew those conventions and produced, over several decades, a remarkably original body of work that, for sheer inventiveness and virtuosity of prose style, gained him international acclaim. Joyce's novels virtually defined modernism in literature, influenced several generations of writers, and continue to exert a fascination for serious readers.

The early work *Dubliners,* a collection of penetratingly observant short stories, was followed by the autobiographical novel *Portrait of the Artist as a Young Man,* which introduced experimental techniques that Joyce later explored fully in the radically innovative novel *Ulysses.* Finding the atmosphere of Ireland to be stiflingly parochial and repressive, Joyce resolved to live as an expatriate in order to maintain fidelity to his vocation as an artist. Composed in Paris, Trieste, and Zurich, where Joyce and his wife Nora had taken up successive residences after leaving Ireland, the novel *Ulysses* was completed in 1921. This book, Joyce's masterpiece, focuses on the lives of several residents of Dublin whose paths intersect over the course of a single day. In planning *Ulysses* Joyce took enormous pains to follow a rigorous outline that, beneath the surface of the novel, incorporates detailed parallels between the day's events and the major episodes of the *Odyssey,* a classical Greek epic work attributed to the poet Homer. Published in France, Joyce's novel was immediately recognized for its masterful use of the technique that became known as *stream of consciousness.* This literary tool, afterward widely imitated, became a mainstay in modernist literature, using a constant flow of subjective observations, reactions to events, reflections, and ideas as they pass through a character's mind, providing a uniquely intimate view of a character's mentality. Most famously, the final chapter of *Ulysses,* commonly referred to as Molly Bloom's soliloquy, is a lengthy, labyrinthine, richly associative interior monologue composed of only three sentences. As if to remind his readers that time presses on even at the close of a story, Joyce allows for the final lines of the novel to linger on a slight and momentary notion.

Owing to chronic poverty and the pressures of family, specifically the deteriorating mental health of his daughter, Lucia, Joyce found himself exhausted upon completing *Ulysses.* After a year's hiatus he began writing again in 1923. A work in progress that would eventually become *Finnegans Wake* occupied Joyce for more than 6 years and involved the use of narrative techniques and multilingual word play that left even the highly inventive idiom of *Ulysses* far behind. A complex amalgam of myths and folktales, archetypal themes, and timeless stories told in a unique style of language filled with puns, wordplay, and allusions to events that span world history, the novel posits the idea that history is not linear but cyclical and is bound to repeat. In this Joyce echoes the philosopher Friedrich Nietzsche's idea of eternal recurrence; in this way the *Wake* opens onto a vista that embraces all of human endeavor, encompassing past, present, and future. The final passage of the book ends in midsentence, continuing with the first phrase on the first page, thereby manifesting the very cyclical nature that Joyce came to see as a fundamental not only to the act of storytelling but also to the universe itself.

In the last decade of his life, internationally famous and with his literary reputation secure, Joyce became nearly blind, undergoing a series of eye operations that were only partially successful and were complicated by alcoholism. He died in Zurich in 1941 following surgery for a stomach ulcer.

JUDAISM

Judaism is the religious, ethnic, and cultural heritage derived from the ancient people of Israel and the Hebrew scriptures. While the practice of Judaism is centered around the books of the Hebrew Bible, and among those primarily the five books of the Torah, its developed form, often referred to as a civilization, represents the accumulation of custom and tradition over centuries of thought and writing.

Intriguingly, many of the most central aspects of Judaism are connected to unique ways of measuring time and marking its passage. Judaism follows a nuanced calendar that prioritizes the cycles of the moon over the revolution of the earth around the sun. Within this calendar, the Jewish year is given distinct color and texture by numerous holidays and festivals that make up the liturgical schedule for worship. Through this continuous liturgical cycle that celebrates milestones of national and historical significance, Judaism captures both the cyclical and linear elements of time. Each year moves forward into history but also repeats the same journey as those before it—for example, the complete reading of the Torah, the celebration of special days like Pesach, Shavuot, or Sukkoth, and the blast of the *shofar* to greet the new year on Rosh Hashanah. Throughout its long history, Judaism has also contributed significantly to the discussion and philosophy of time. The ancient Hebrews solidified their religious and cultural identity in part by their beliefs concerning the beginning of time and the creator God who moved it forward through history. Centuries later, medieval Jewish thinkers grappled with influential philosophies of time originating outside their tradition and tested their compatibility with Jewish theology. In the European Age of Enlightenment, with the relaxation of strictures forbidding Jews from participating in civic culture, Jewish thinkers and philosophers engaged more freely in dialogue and debate with their Christian counterparts. Today, as full participants in secular society, observant Jews still preserve ancient customs revolving around the Jewish calendar and religious year.

Jewish Calendars and Chronology

Throughout most of its history, Judaism has used a calendar based primarily on a lunar year with necessary intercalations made to avoid excessive divergence from the solar year. This year is divided into twelve lunar months: Nisan, Iyyar, Sivan, Tammuz, Av, Elul, Tishri, Heshvan, Kislev, Tevet, Shevat, and Adar. In leap years, an extra intercalary month called Adar II is added. The names of these Jewish months closely resemble Babylonian month names, a probable result of the 6th century BCE exile of the Hebrew people in Babylon.

Each month begins at the new moon, or *molad* ("birth" in Hebrew). Since the average lunar month is approximately 29.5 days, the Jewish months alternate between 30 and 29 days in length. This results in a typical year of around 354 days and a leap year of around 384 days. The present system of leap years is based on a 19-year cycle in which the 3rd, 6th, 8th, 11th, 14th, 17th, and 19th years are intercalated with a 13th month. Originally, the commencement of new months and insertion of leap months were physically observed rather than calculated. New moons were observed and announced to Jewish communities by the religious leadership, and leap months were inserted when it was observed that the calendar and festival cycle were deviating too much from the agricultural season. In the 4th century CE, patriarch Hillel II formulated a new mathematical foundation for the calendar that introduced the 19-year cycle of leap years and diminished the need for physical observation. His calendar method was refined for the remainder of the 1st millennium and has remained essentially unchanged since that time.

For Judaism, the day begins and ends at dusk, rather than midnight. Thus, the Sabbath begins at sundown on Friday of the secular calendar and ends 24 hours later. For the reckoning of times for daily prayers and observances, 24 uneven hours (proportionate divisions of the daytime and the night) are used, while 24 even hours are used for most other purposes. Rather than minutes and seconds, Jewish custom divides the hour into 1080 *halakim,* which equal about 3.5 seconds each.

A potentially confusing aspect of the Jewish calendar is the starting point of a new year. Originally, Nisan corresponded to the "1st month," as was the case in the Babylonian ordering of the months. Likewise, it is between Adar and Nisan that the leap month Adar II is inserted. Despite this fact, the 1st day of Tishri is actually considered the start of the new year, called Rosh Hashanah, approximately corresponding with the autumnal equinox. Though Rosh Hashanah is the 1st day of the month of Tishri, it does not always occur on the day of the *molad.* In the interest of avoiding certain scenarios, such as Yom Kippur being a Friday or Sunday, Rosh Hashanah is sometimes delayed by one or two days. Because of this, the year always begins on a Monday, Tuesday, Thursday, or Saturday. An individual year is succinctly described by three facts that determine liturgical schedules: the day of the week of Rosh Hashanah, the number of days in the year (353, 354, or 355 for regular years; 383, 384, or 385 for leap years), and the day of the week on which Passover begins.

Standard Jewish chronology numbers the years from the supposed date of the Creation of the world, sometimes indicated by the abbreviation AM for *anno mundi,* "year of the world." Though various calculations have been made by Jews and Christians based on biblical genealogies and histories, Jewish dating accepts the conclusion attributed to 2nd century rabbi José ben Halafta that the Creation occurred in the year 3761 BCE. By this chronology, the year 5768 corresponds with 2007–2008 CE.

While the calendar system described above reflects the mainstream of Jewish tradition throughout its history, there have been dissidents. Most noteworthy is a group of solar calendars described in the 2nd century BCE book of *Jubilees* and in multiple versions of the book of *Enoch.* The main calendar of this type was distinctively solar, describing the year as 364 days or exactly 52 weeks. These calendars are generally regarded as sectarian within the Judaism of their time, and there is little evidence to determine the extent of their observance. Materials referring to such calendars have been discovered at Qumran, but references to other systems make it unclear exactly what calendar the Qumran sect observed. Clearly, the 364-day calendar would drift from the actual 365.5-day solar year at a steady pace, but no intercalation method is mentioned in literature connected to these calendars, a fact that causes some to doubt their sustained observance.

The Sabbath

Throughout history, a primary distinguishing characteristic of Judaism has been the observance of the Sabbath (or Shabbat), a day of rest observed on the seventh and final day of each week. The Sabbath has been central to Jewish identity since ancient Israel, and it figures prominently throughout the Hebrew Bible. Biblical passages connect the institution of the Sabbath with God's 7-day Creation of the world, the Israelite wanderings in the wilderness, and the Decalogue. Prophetic texts sternly rebuke neglect of the Sabbath in Israel, while later rabbinic writers further delineate what would be acceptable and unacceptable on the Sabbath. Jews observe the Sabbath (which actually runs from Friday evening until Saturday evening) as a time of relaxation, prayer, and worship. Food is prepared ahead of time, and most activities classified as "work" are prohibited. Most of the Sabbath is spent together by families at home, but synagogue services are typically held on Saturday morning.

While the concept of a 7-day week is taken for granted in modern culture, in the ancient world it was a cultural novelty of Judaism. Because it does not directly follow any natural phenomenon (as days, months, and years all do), the week is one of the more puzzling chronological developments in human civilization. While the Jewish week appears to have been a unique development, there are interesting parallels from the ancient Near East, such as Assyrian "unlucky days," which occurred on the 7th, 14th, 19th , 21st, and 28th days of the month (the 19th is understood to equal seven cycles of seven from the start of the previous month). The 7-day week in its modern form is a combination of the Sabbath-based week of Judaism and the Roman planetary week, which emerged around the turn of the common era. A further development was a Christian adoption of the 1st day of the week, Sunday, as its day of worship and rest after the day of Jesus' resurrection, contributing to the development of the 2-day weekend now widely observed.

Jewish Holidays

The Jewish year is given shape by a number of festivals and holidays that are central to Jewish religious life. These observances provide a liturgical cycle of worship, a continuous revolution that commemorates annual occurrences and special events from Jewish history. Because of the original uncertainty or delayed information concerning the fixing of new years and months, especially for diaspora Judaism, a second day was added to most festival days, a convention that is still maintained despite more precise methods of calculation.

Of special importance for Judaism are the 3-week-long pilgrimage festivals (Passover, Shavuot, and Sukkoth), which are each tied both to events from the biblical history of Israel and to agricultural seasons. Passover (or Pesach), beginning on Nisan 15, is connected with the Israelite exodus from Egypt and the beginning of the spring harvest. The most widely celebrated Jewish holiday, Passover, is commemorated with a special seder meal. Shavuot (the Feast of Weeks or Pentecost) follows Passover by 7 weeks and celebrates the giving of the Torah at Mount Sinai, as well as the end of the barley harvest and the beginning of the wheat harvest. On the 15th of Tishri, Sukkoth (the Feast of Booths or Tabernacles) recalls the Israelite wilderness wandering and celebrates the ingathering of grain from the fields into barns. Observers of Sukkoth construct a *sukkah,* a simple booth, in which they are to dwell during the 7 days of the festival.

In addition to the three central festivals, many other special days mark the Jewish year. As explained above, Rosh Hashanah ("head of the year") occurs at the beginning of Tishri, in autumn. The Jewish new year is ushered in with the blasts of a *shofar,* a ram's horn, and marked with a day of introspection and special synagogue worship. Shortly after the start of the new year on Tishri 10, Jews observe Yom Kippur, the Day of Atonement. This is the most somber of Jewish holidays, marked by fasting, abstinence from work, and lengthy synagogue services of confession and repentance. Other significant occasions include Shemini Atzeret ("assembly of the eighth day") and Simhat Torah ("joy of the Torah"). These immediately follow the 7 days of Sukkoth in Tishri, and Simhat Torah marks the completion of the annual cycle of readings through the Torah, the first five books of the Hebrew Bible. Purim is a celebration of Jewish survival from Persian oppression, revealed in the book of Esther, and is held on Adar 14 or Adar II 14 in leap years. Hanukkah, the Festival of Lights or of Dedication, is well known for its proximity to the Christian Christmas holiday and commemorates the miraculous burning of a menorah lamp for 8 days at the rededication of the Jerusalem temple in the 2nd century BCE. This holiday is celebrated for 8 days, beginning on Kislev 25 with the lighting of candles in a menorah.

Time in Jewish Thought and Literature

Though the ancient people of the Hebrews do not seem to have developed any extensive philosophies of time, among ancient civilizations they were pioneers of the concept of historical identity. In some sense, the entire development of the Hebrew Bible and subsequent Jewish tradition centered around the conviction that historical events that made up the progression of time had meaning and purpose. It was the activity of humanity (guided by the hand of God) that made up history or time for the ancient Hebrews rather than purely abstract measurements or theories. Modern scholarship does assert that the Hebrew scriptures are not "historical" in the modern sense; they represent a mixing of mythology, historical reality, and theological-historical interpretation. Still, it is precisely through these mediums that they communicated the narratives that formed the Hebrew identity and gave meaning to the progression of time. This begins with the very first passage of the Hebrew Bible, which asserts that time began with the Creation of "the heavens and the earth" by God. This affirmation became, for both Jewish and Christian thinkers, a frequent point of contrast with Greek philosophies, which often argued for the eternality of matter and a cyclical nature of history.

In addition to prescribing a beginning of time at Creation, the ancient Hebrews developed beliefs concerning the end or consummation of time, generally classified as "eschatology." The seeds of Jewish eschatology are present even in the Torah, as the concept of Israel as God's chosen people becomes fully developed, but it is the prophetic writings that contain the bulk of Jewish eschatological language. As the course of Israelite history grew darker and the prophets struggled with what they considered unfaithfulness to God among the Israelites, the focus turned increasingly toward concepts of future divine judgment. Terms such as "that day" and "the day of the Lord" became common indicators of a coming time when God would intervene on a universal scale, judging all peoples and setting right the injustices of the world. Within this realm of thought, the concepts of a messiah and of life after death developed and grew, particularly in late prophetic and intertestamental literature. Increasingly, the hope of resolution of injustice in the world was pushed to a future time, when all people would be resurrected and face judgment.

By the medieval period, many Jewish philosophers interacted with classical Greek traditions about the subject of time. Moses Maimonides accepted a primarily Aristotelian concept of time, in which time was an "accident" of the motion of physical bodies. Hasdai Crescas, on the other hand, rejected the Aristotelian conception and connected time to the consciousness of the mind, not motion, a concept more akin to that of Plotinus. For these and other philosophers, numerous questions of God's relationship to time became pressing: Does God exist within time or outside of it? Was there time before Creation? If so, what was God doing during that time? Can "eternity" be understood in the normal sense of time? Such questions were discussed among Jewish thinkers as well as theologians of the Christian and Islamic traditions with diverse and varying answers. For both monotheistic faiths, the philosophical questions of time, eternity, and cosmogony have been a constant component of theological discussion.

Judaism in the modern world is very diverse and difficult to characterize as a whole. For many, Judaism is more a cultural than religious identifier. Despite this, observing time by the traditional calendar and customs of Judaism remains a central aspect of faith for many. Keeping the sabbath is fundamental to being a Torah observer, and the Jewish calendar system is still the framework of worship. The richness of Jewish customs regarding time and their persistence throughout history, even in the face of modern secular assimilation, testifies to the remarkable character of Judaism as a religious, cultural, and ethnic entity that has preserved a genuinely unique identity.

KABBALAH

Kabbalah, derived from the Hebrew root meaning "to receive," is the name given to a Jewish mystical tradition that originated around 100 BCE. Owing to variations in transliteration from the Hebrew, it is sometimes rendered as Kabalah, Qabalah, or Qabbalah. The name Kabbalah is attributed to the scholar Isaac the Blind (c. 1160–1236), sometimes called the Father of Kabbalah, although the practice of Kabbalah predates him. As a form of Jewish mysticism, it is primarily concerned with directly experiencing God through meditation, spiritual exercises, or interpretations of scripture (particularly the Torah) and other writings. Kabbalah has both a traditional and a distinct beginning.

Traditionally Kabbalah is believed to date from the relationship between Adam and God. According to the first three chapters of Genesis, Adam enjoyed a unique experience with God: Adam conversed directly with God without any mediation from another person or text. He was able to know God face-to-face. This is the kernel of mysticism in general and Kabbalah specifically: to know God directly.

Viewed this way, many persons from the *Tanakh* (Hebrew Bible; in Christianity, the Old Testament) are viewed as having kabbalistic experiences. According to Jewish teaching, the events in the book of Genesis occurred prior to God giving the Law of Moses. Within Genesis, people speak with God directly. While Genesis makes no mention of the type of relationship between Melchizedek and God, Melchizedek (Gen 14: 18–20) is mentioned as a priest of God prior to the establishment of the Torah (Law). Therefore (the reasoning goes), because there was no mediation, Melchizedek must have had a direct experience with God. Abraham spoke directly with God (Gen 12–22) as did Moses (Exodus through Deuteronomy).

In other books of the Tanakh, prophets are mentioned as having direct experiences with God. This is important for understanding Kabbalah, because the prophets had experiences with God after the Law of Moses was given. To a Kabbalist, therefore, the Law of Moses does not stand between a follower of God and God, such as in the role of a mediator, but instead the Law of Moses becomes a gateway into communication with God.

Kabbalah has a distinct beginning that can be traced to a wealth of Jewish mystical literature from the period 100 BCE to 1000 CE. Over time, the literature and understanding of Kabbalah increased. Yet the central Kabbalah text is the *Sefer ha-Zohar* (Book of Splendor), which is usually given simply as Zohar. The Zohar contains commentary and stories. Its preeminence among Kabbalah is borne out by the number of commentaries that have been written about the Zohar. This book is attributed to Simeon bar Yohai (2nd century CE), although the first record of the book is from the 13th century in Spain as the work of Moses ben Shem Tov de Leon (1240–1305). He either edited the writings of Simeon bar Yohai or based his work on Simeon; in either case the work originated with Simeon and was completed by Moses de Leon.

Soon after the Zohar, *Ma-arekhet ha-Elohut* (The Order of God) appeared, which attempted to systematically explain Kabbalah doctrine. In addition, *Sefer ha-Bahir* (Book of Light) was another early Kabbalah text that explained the *sefirot* (the emanations of God).

A central tenet of Kabbalah is the tree of life. This symbol contains a diagram (sometimes represented as a tree) with ten sefirot (emanations): sovereignty, foundation, endurance, majesty, beauty, loving kindness, judgment, wisdom, understanding, and the crown. The sefirot exhibit different aspects of God. They are to be viewed as a unit and individually. As a unit, these represent the way that God communicates or interacts with the world. Individually, these are steps along which the kabbalist works or progresses in an attempt to draw closer to God.

Prominent teachers of Kabbalah include Moses Cordovero (1552–1570), who wrote *Tamar Devorah* (Palm Tree of Deborah), which explains Kabbalah, and *Or Yaqar* (Precious Light), which is a commentary on the Zohar. Isaiah ben Abraham ha-Levi Horowitz (1565–1630) wrote *Shenei Luhot ha-Berit* (Two Tablets of the Covenant). Isaac the Blind (c. 1160–1235) is believed to have written the *Sefer ha-Bahir* (Book of the Brightness). Over time, texts and commentaries on Kabbalah have been written and collected, and interest in the texts has increased both within and outside Judaism.

Similar to other mystical traditions, Kabbalah considers time and space as mundane realities. Within the spiritual realm, therefore, concepts such as time, space, and place are nonexistent. Understanding God entails understanding his actions apart from time; God's qualities exist beyond time and cannot be limited or perceived by temporal constraints. This in itself tends to restrict interest in Kabbalah to truly serious adherents, because practitioners must remove themselves from the physicalness of their surroundings in their efforts to fully understand God.

Among Jewish religious groups, the Kabbalah greatly influenced the ultraorthodox Hasidim. This influence can be seen in the Hasidic theology of working toward a union with God and in their concept of *devekut* (from the Hebrew for "cleaving," the cleansing or preparation of prayer and mediation toward God).

In understanding the intent toward the Torah of Kabbalah, the teaching of Bahya ben Asher is instructive. He held to four different interpretations of scripture: the literal, the homiletic (preaching), the moral, and the mystical. The Kabbalah is not solely interested in the mystical meaning of scripture, yet it is concerned with utilizing the former three while focusing on the mystical. For the kabbalist, the Torah does not solely teach people about God and how to live before God; instead it starts with those and brings the person into communication with God.

Kabbalah texts can be difficult to understand, many being written in esoteric language. Additionally, some kabbalists in the past believed that no one under the age of 40 should practice Kabbalah. Kabbalah was understood to be reserved for those willing to devote themselves to a mystical relationship with God.

Recently, more accessible forms of Kabbalah have become popularized and are currently practiced by people from various backgrounds, both Jewish and gentile. Kabbalah centers can be found in major cities worldwide, and a number of Web sites offer instruction and guidance in teachings that are based on elements of the kabbalistic traditions.

Kafka, Franz (1883–1924)

Franz Kafka, among the most highly acclaimed writers of the 20th century, was a Jewish

Czechoslovakian who wrote allegorical stories in the German language. As literary critics have pointed out, Kafka's meticulously constructed tales seem to defy categorization, containing elements of the comedic and satirical as well as the tragic. He has been described as a realist, an absurdist, a Marxist, a sociologist, an existentialist, and a comedic theologian. Now widely considered the paradigmatic artist of his time, Kafka developed a personal idiom of expression that imposed a unique literary order on the disorder of the emerging modern world and gave universal form to his own personal nightmares and obsessions. Many later writers have acknowledged Kafka's influence, including Jorge Luis Borges, Milan Kundera, Gabriel García Márquez, Carlos Fuentes, and Salman Rushdie.

A striking aspect of Kafka's work is in its uncanny foreshadowing of the nightmare of bureaucratic control and mechanized murder that, more than a decade after Kafka's premature death from tuberculosis, would take shape as the Holocaust. In his novels *The Trial* and *The Castle,* both published posthumously, the central characters undergo persecution by petty officials: Joseph K. is anonymously accused of a crime whose nature remains unspecified; his attempts to clear himself only draw him deeper and deeper into a labyrinthine legal system that ultimately issues a death sentence carried out in an impersonal and humiliating manner. The protagonist of *The Castle,* who is identified only by the initial "K.," is repeatedly thwarted by a succession of bureaucrats and office holders in his efforts to gain access to the forbidding, enigmatic structure and ultimate source of power that dominates the town where the story is set.

A sense of oppression and anxiety characterizes much of Kafka's literary output. In the novella *The Metamorphosis,* which was published during Kafka's lifetime and received considerable acclaim, the main character, Gregor Samsa, a traveling salesman and the primary breadwinner for his mother, father, and sister, awakens one morning to find himself transformed into a giant insect. His efforts to confront the reality of this existential nightmare are described in such a way as to convey the dark humor as well as the horror of his situation.

Other acclaimed stories include "The Judgment," "In the Penal Colony," "A Country Doctor," and "A Hunger Artist," as well as the unfinished novel *Amerika,* the first chapter of which is the acclaimed story "The Stoker."

Kafka was born in the cosmopolitan city of Prague, Bohemia, which is now part of the Czech Republic. His father Hermann, a businessman, was physically imposing, overbearing, unsympathetic, and intimidating, and their relationship, always difficult, grew more strained as the years passed. The primordial theme of father-son conflict would emerge in Kafka's writing again and again in the form of confrontations with remote and sometimes hostile authority figures. Kafka refused to work in the family business, intent instead on a university education. After several years of changing majors at Ferdinand-Karls University in Prague, he went on to earn a doctoral degree in law.

As a student Kafka made acquaintances with other intellectuals and aspiring artists. He befriended Max Brod, a lifelong friend and confidant, to whom he would later entrust his literary estate. Throughout Kafka's life, he would continually battle bouts of physical, emotional, and mental exhaustion and would seek rest and treatment at sanatoriums. His first sanatorium stay occurred before he finished his law degree in 1905. In 1906, just after graduation, the pressures of family, professional, and scholarly pursuits overcame him, and again he sought the refuge of the sanatorium.

Two years after graduation, he took employment as an attorney with the Worker's Accident Insurance Institute for the Kingdom of Bohemia, where he worked diligently until shortly before his death. While in this employment, Kafka wrote several articles on the prevention of industrial accidents. In 1909, he published his first stories, excerpts from an abandoned novel, *Description of a Struggle,* in the journal *Hyperion.*

Kafka's complex inner life and his ambivalence concerning intimate relationships caused him to break off several affairs and marital engagements. As a young man, he would confess to his friend Brod that he was unsuitable for marriage and that he could never love a woman if she returned that affection.

Kafka obtained an early retirement from his long-term employer, and in 1922 he wrote "Investigations of a Dog'" and *The Castle.* By this time his health was seriously affected by the chronic tuberculosis that would eventually take his life. He lived transiently between sanatoriums and his sisters' homes. In 1922, he befriended a woman named Dora Dymant, with whom he lived briefly and to whom he eventually proposed marriage. Early in 1924, however, increasingly ill and near death, he traveled back to Prague, where he lived briefly with his parents and wrote "Josephine the Singer." He died on June 3 in a sanatorium near Vienna.

Although Kafka had directed Brod, his literary estate executor and lifelong friend, to destroy all his unfinished manuscripts, Brod salvaged the unfinished manuscripts instead. In the1920s three novels were posthumously published, and in 1931 a collection of incomplete tales was printed, together establishing Kafka as a 20th century literary master who, against the background of a decaying empire, had prophetically glimpsed the outlines of the world that was soon to come and had responded with a sense of dread and foreboding.

Kant, Immanuel (1724–1804)

Immanuel Kant, like Plato and Aristotle, counts as one of the most influential philosophers of all time. He developed a new theory of time and space that combined insights from rationalism and empiricism. In his practical philosophy he developed a completely new approach, which makes Kant one of the most distinguished scholars of the European Enlightenment.

Kant was born in Königsberg (formerly East Prussia, since 1945 renamed Kaliningrad, Russia) on April 22, 1724, as the son of a saddler. He was brought up in the spirit of Pietism, a Lutheran movement that focused on love, which is realized through duty and good deeds. He never left Königsberg. It was there where he went to school and attended university, where he received permission to teach as a university lecturer (*Privatdozent*) in 1755, and again where he was appointed full professor of logic and metaphysics in 1770 after declining an offer from Jena in 1769. He held this position for the rest of his life and died on February 12, 1804.

The tone of the German intellectual landscape in which Kant started his work was largely set by the so-called "school philosophy" of Leibniz and Wolff, a thoroughgoing form of rationalism. Wolff, continuing Leibniz's work, believed that every truth of reason could be deduced from the principles of noncontradiction and sufficient reason. When Kant encountered Hume's empiricist philosophy, he felt awakened from his dogmatic slumbers. In 1770 he consolidated many of the intellectual gains he had made during the 1750s and 1760s in his Latin inaugural dissertation (*Habilitationsschrift*). He introduced an important new theory about the epistemology and metaphysics of time (and space). His fundamental new philosophical insight, which he later elaborated in his famous work *Critique of Pure Reason,* goes as follows:

> 1. The idea of time does not arise from the senses but is presupposed by the senses. . . . 5. Time is not something objective and real (*tempus non est obiectivum aliquid et reale*); it is neither an accident, nor a substance, nor a relation; it is the subjective condition, necessary because of the nature of human mind, of coordinating everything that we experience (*quaelibet sensibilia*) by a certain law, and is a pure intuition. For we coordinate substances and accidents alike, as well according to simultaneity as to succession, only through the concept of time.

The same holds for space, which he maintains is also neither objective nor real. Kant combines

Hume's empiricist point of view with the rationalistic assumption of an ordered universe. Hume believes that with sense-knowledge, the given consists of impressions and sensations, and, for this reason, we can only discover post hoc a succession in time without causal relation. Rationalists assume that there is a fundamental causal connection between events (a post hoc principle of sufficient reason). Kant explains that time and space, as our subjective forms of intuition, are the reason why we have the experience of causal connections without holding that these causal connections are real in an absolute sense. But they are real to us, because all human beings have the same experience, which results from the notion that all human beings have the same subjective forms of intuition; that is, of time and space. Kant's position on time and space is of great philosophical interest. For example, Einstein's theory of relativity shows that it is not possible for us to have absolute time or space, so it seems to be true that our experiences are just of appearances and do not tell the whole story.

In his *Critique of Pure Reason* (1781/1787) Kant developed these important insights to encompass all the categories used in thought. However, Kant admits that this work does not describe the whole system but instead is the blueprint for a new transcendental philosophy, thereby destroying the metaphysics of the past. Kant's central idea is to argue that the unity of consciousness, the so-called transcendental unity of apperception, categorizes all of the sensations according to the forms of intuition (time and space) and the forms of intellect; that is, the pure concepts (categories). This explains why there are universal and necessary laws for every being with consciousness and intellect, in other words, for every human being. Kant calls this knowledge synthetic a priori, because it is necessary and universal, on the one hand, but is not inferable through the analysis of concepts, on the other. From that follows that "things" that are not explicable in space and time, for example, God or an immortal soul (if they exist), cannot be assessed by human beings without leading to an endless series of irresolvable disputes. The previous system of metaphysics is now null and void. As a result, we cannot derive ethical conclusions from theological (or metaphysical) "knowledge" of the good. We are left without a solid foundation for a consequentialist account of ethical reasoning.

Kant proposes an alternative theory of practical reasoning that can be found in *Fundamental Principles of Metaphysics* (1785), *Critique of Practical Reason* (1788), *The Metaphysics of Morals* (1797), and numerous sections of other works. He assumes that only a will that acts for the sake of duty and not for the sake of inclination is a morally good will. The will is good when, for the sake of duty, it follows the fundamental commandment he calls the "categorical imperative," a principle of action that is a universal moral law. All rational beings endowed with freedom, regardless of their particular interests and social background, have to adopt this principle. Kant formulates it in the *Groundwork for the Metaphysics of Morals* in four different ways. The most famous formulation is as follows: "Act only according to the maxim (the determining motive of the will) through which you can at the same time will that it become a universal law." By *universal law* Kant means that this principle does not allow for exceptions, in contrast to the laws of nature. Another formulation of the categorical imperative demands the impartial respect of humanity in every human being: "Treat humanity . . . never simply as a means, but always at the same time as an end." Here Kant introduces the concept of human dignity, which remains among the most discussed of all ethical concepts.

In his third critique, the *Critique of Judgement,* Kant tries to unite theoretical and practical reason. Nature can be understood as a determinate system only under the regulative idea of being a system serving an ultimate end. This idea is regulative because it helps us to understand nature according to our capacities of reason. Consequently, we do not know whether nature serves an ultimate end at all; instead we are just left to postulate it.

Many aspects of Kant's theoretical and practical philosophy have been questioned, in particular his assumption of synthetic a priori propositions and his ethics of the categorical imperative. His theory of time and space, however, will likely remain a cornerstone of philosophical thought for generations to come.

Kierkegaard, Søren Aabye (1813–1855)

Søren Aabye Kierkegaard was a Danish literary author, philosopher, and theologian whose work has had an abiding influence on philosophy, especially existentialism and postmodernism in the 20th century. His wide-ranging thought focuses largely on points where theological explication of the Christian faith and philosophical investigation of concrete human existence intersect and inform one another. Throughout his authorship, Kierkegaard proposed different understandings of existential (and theological) human temporality—how the human individual dwells and relates to himself or herself and the eternal order in the midst of time.

For Kierkegaard, time itself is a fluid and infinite succession of discrete points that are passing by. This succession is one of ceaseless quantity that spreads out extensively. Temporality, taken as signifying the temporal domain, is characterized in Kierkegaard's work as a realm of plurality (difference) and becoming (movement). This becoming is not a necessary one. All finite, temporal actuality for Kierkegaard is contingent; it could have been another way if another possibility had been actualized. (It is for this reason that human understanding or knowledge of events in time, in history, involves an irreducible uncertainty due to the contingent status of its objects.) In the midst of this fleeting impermanence, any given moment in time—from the perspective of time alone—is an infinite vanishing, a nothing. Considering time as such, there is no present and thus no past or future. There is only the infinite succession. The differentiation and distinction into present, past, and future only arises in the relation of time to another order—to the eternal.

The temporal, for Kierkegaard, is understood in contradistinction and dialectical relation to the eternal. Generally, the eternal is presented as an eternal present—a present in full in which the relative succession of time is annulled. (For Kierkegaard, in a sense, the present is eternal before it is temporal.) "The eternal," while it is used in various ways throughout Kierkegaard's authorship, refers more specifically to the transcendent God and that which has to do with one's relation to him (such as one's moral ideals and one's future life beyond death). Kierkegaard presents God as the source of ethical-religious stability in human existence that, in himself, transcends the temporal order (see below). As opposed to the ancient Greek intellectual conception (in Kierkegaard's estimation) of eternity in the form of abstract ideas, Kierkegaard affirms the Judeo-Christian "eternal" of a personal creator God who transcends history and yet actively relates to it—in its origin (creation), its progression (guiding and interacting), and its consummation. It is the divine eternal that makes time into something like unified narrative.

Following the Judeo-Christian understanding, Kierkegaard understands the eternal God as creating the temporal-finite order out of nothing. This created temporal realm is that of "existence"—of what has come to be in contingent finite-historical becoming, for the temporal realm as a whole, as freely created by God, could have been otherwise. In Kierkegaard's writings, existence is primarily discussed as the realm of ethical coming-to-be, of human existence and self-becoming.

The existing human being, for Kierkegaard, is a synthesis of the temporal and the eternal. The human at once dwells in time and relates to the eternal in *the moment*—a point in the succession of time at which an individual comes into contact with something of an order other than the finite-temporal. The moment is where the "present" of the eternal relates to time (where there is no present as such) in human consciousness. In the moment, time is meaningful (is more than mere succession) inasmuch as it relates to a transcendent order. It is only now that temporality—in terms of present, past, or future—is truly posited.

In Kierkegaard's anthropology, the existing human self is an identity that is actively produced in and through time. Human living and temporality are understood in terms of *repetition*—the project of trying to make of one's life something of the eternal, the stable, the abiding. For Kierkegaard, "aesthetic" repetition, the attempt to make pleasurable experiences permanent, fails because of the discontinuous and contingent nature of time. In ethical-religious repetition, however, one attempts to forge an identity through the discontinuity and becoming of time. In moral commitment, one seeks to establish a continuity over time—a continuity of temporal moments relating to the eternal—in which one becomes a self by relating to the eternal, ultimately to God. Here the unity of the self comes to be in the midst of the instability of time relative to something stable transcending time. The willing of one thing (God, the good, the eternal) in the midst of the plurality of one's temporal life makes one into one—into one thing—into a self.

The problem in establishing this self as a continuity over time is that of sin, of moral failure. When one considers the moral task of repetition along with the possibility of freedom, one encounters a psychological state of *anxiety* regarding the possibility of sin, of moral failure. Anxiety, for Kierkegaard, specifically relates to dwelling in time. For anxiety has to do with the human spirit's awareness of itself as free, as being able to actualize various non-necessary possibilities in the future—namely with the possibility of moral failure. Anxiety has to do with the tension in the synthesis of the self between our dwelling in time as finite beings and our "spiritual" relating of our finite lives to the eternal. Our freedom to act (in relation to the eternal, rightly or wrongly) and our responsibility for our actions incites anxiety over the very real possibility of failure—a kind of dizziness of freedom. In such a failure, one fails to relate to God and to relate to one's self as a dependent being-in-relation to God—not wanting to be what one is, failing to be a self.

Kierkegaard, as a kind of Christian theologian, affirms the *incarnation* of the eternal God in the historical person of Jesus Christ. In Jesus Christ, the incarnate God-man, there inheres a paradoxical unity of the eternal and the temporal, the divine and the human. The eternal entered into time in order both to save humanity by reconciling individuals to the eternal as a gift and to provide a prototype of the eternal moral character of God in a human life. The human individual comes into contact with this event of the eternal in time *in the moment* of Christian salvation. As at once a supreme if not archetypical instance of the ethical moment (see above) and an analogue of the incarnation, the moment of Christian salvation is a moment in time that has eternal significance. Kierkegaard observes that in this intensive moment of relating to Christ in salvation inheres the paradox that something eternal (one's eternal salvation) can be decided in time. Kierkegaard writes that it is quite understandable that this is something that does not "make sense" in the order of temporality alone—that a moment can be more than merely one moment among moments. In the moment of the possibility of one's salvation, one meets the moment of the incarnation with faith or offense. In *faith,* one believes and accepts that in Christ the eternal to which one has failed to attain a proper and consistent relationship in one's temporal life has come into time and given itself to one as a gift. In this moment of receiving the gift of salvation, there is a *contemporaneity* with Christ—for, in the moment of faith, the moment of the incarnate Christ's being in history is "present" to one. Through the gift of Christ and the example of his life, one can attain an identity that is not a mere aggregate of equivocal points of time in succession—one can become a self in relation to God.

Knezević, Bozidar (1852–1905)

As a science-oriented philosopher and historian living in Yugoslavia during the emergence of Darwinism, Bozidar Knezević was greatly influenced by the theory of evolution. He extended Darwin's process view of life on earth to include the future of organic evolution on this planet within a cosmic perspective. Knezević's philosophy of time and evolution was presented in his two-volume work *The Principles of History* (1898–1901). His incredible vision was a mixture of facts, concepts, and rational speculations that embraced both the ascent and subsequent descent of life forms on earth (including our own species) over a vast period of time.

Knezević acknowledged the awesome immensity of this dynamic universe in terms of both time and space. He claimed that humankind is merely a fleeting aspect of cosmic reality. Focusing on our planet, he saw three major stages of material development: inorganic, organic, and psychic levels of evolution. Within this sweeping perspective, our species recently emerged on the earth. Like all other forms of life, Knezević maintained that humankind is subject to the same finite history of evolution and then devolution that will eventually engulf all species on this planet. He referred to this history as the semicircular model of cosmic reality in general and organic evolution on earth in particular. This geometrical scheme is an engaging approach to understanding and appreciating the vulnerability of life forms throughout time.

According to Knezević, the history of our planet has been a material evolution of organic forms from simplicity to ever-increasing complexity, from the first appearance of the earliest life forms and then the fishes, through amphibians and reptiles, to mammals and the recent emergence of humankind. In the future, he speculated that organic evolution will result in the disappearance of life forms: Humans will vanish first, this will be followed by the extinction of the other mammals, then reptiles and amphibians will vanish, and finally the fishes and simplest organisms will become extinct. As the last species to emerge in evolution, humankind will be the first form of life to disappear; our species is linked to the fatal destiny of the earth and this solar system. Likewise, the first life forms to appear on earth will be the last forms of life to vanish.

For present environmentalists, this semicircular model of organic evolution may be relevant to a meaningful degree. If our planet changes significantly, then it could be the fact that the more complex life forms will become extinct first, while the fishes and invertebrates will survive much longer, far beyond the duration of mammals, reptiles, and amphibians. Eventually, perhaps even bacteria and viruses will vanish from the earth.

For Knezević, time is both creative and destructive. Through evolution, time created the enormous diversity of organisms on this planet, as well as life forms and intelligent beings on other worlds. Through devolution, time will destroy all life among the galaxies. Knezević also envisioned all other planets, galaxies, and entire universes passing through such a semicircular history. Collectively, all these semicircular histories represent God as an infinite series of creations and destructions within the endless flux of cosmic reality. Only matter itself endures throughout time, while time creates and destroys all objects and events in a process that is both unending and beyond human comprehension.

Kropotkin, Peter (1842–1921)

Peter (Pytor) Alekeyevich Kropotkin, born in Moscow into the Russian aristocracy, was a geographer, revolutionary anarchist, libertarian communist, zoologist, anthropologist, economist, philosopher, and sociologist. His writings were published in several languages and widely discussed, exerting considerable influence, especially among political thinkers and activists of the period preceding the Russian Revolution of 1918.

In the course of his geographic work Kropotkin demonstrated that eastern Siberia was affected by post-Pliocene continental glaciations. As a result of his animal life studies, Kropotkin theorized that mutual aid was the key to understanding human evolution, contrary to the notion of the natural world as shaped entirely by ruthless competition. He suggested that science and morality must be united in the "revolutionary project." Education should be global and humanistic and should empower everyone equally. Children should learn not only in the classroom, but also in nature and in living communities. To him, education and science should be based upon mutual aid and serve as a revolutionary activism with which to transform the entire world. This was not only morally correct, but the only life worth living.

Evolution is influenced and shaped by adaptation to a changing environment and adverse circumstances. Among many animal societies, competition between individuals, though important, is secondary to intraspecies cooperation in the survival of the species. Adaptation to the environment and the struggle against adverse conditions lead to an evolutionary theme, resulting in individuals working in partnership to protect their offspring.

In the animal world, most animals live in societies. Kropotkin felt that the survival strategy of safety was a concept that needed closer examination. This was not just a struggle for existence but a protection from all natural conditions that any species may face. Each individual increases its chances by being a member of a group. Mutual protection allows certain individuals to attain old age and experience. Among humans, these collective groups allowed for the evolution of culture. In the earliest band societies, social institutions were highly developed. In later evolution of clans and tribes, these institutions were expanded to include larger groups. Chiefdoms and state societies shared mutual identities in groups so large that an individual did not know all members. The idea of common defense of a territory and the shared character of nationalism appeared in the growth of the group sharing a collective distinctiveness.

Solidarity gives the species as a whole a better opportunity to survive. Thus, supportive attention for the well-being of relationships of the group is selected for. The manipulative and sly individuals are cleansed from the pool of ancestors, and those most supportive of mutual social life are selected to survive. Along with this, safety in numbers allows for increased chances of survival. Cooperation increases chances of an intelligent response to a threat to the group or the offspring by a coordinated effort. Be it hunters in a pack or herbivores cooperating, these efforts develop social skills and an awareness of comrades. The needs of the progeny and for continued existence bring together groups for reproduction and protection of the young. Because of this, security of all individuals is enhanced through mutual aid.

Ethics are thus a part of natural evolution. The strongest section of social companionship, which is the attraction of all major religions, is learned through the observation of nature. As animal behavior becomes more complex, association becomes less instinctual and more learned. Conscious awareness of the needs of others becomes increasingly important to the survival of the group and all its members. Communication becomes central to sociability. Vocal communication, exchange of ideas, and replication all help to teach collected knowledge to other individuals. Being companionable is an adaptation to the environment, and struggle and friendliness are the main foundations of evolution.

Through cooperation, less energy is expended for gathering food or fighting off danger. Cooperation, observed Kropotkin, favors the evolution of intelligence. Moreover, social feelings are central to development of societies, justice is part of the natural world, and ethics have a biological origin. The struggle for survival most often has a collective origin.

Carrying capacity determines population density, not by the most favorable circumstances but by the most server-limiting factors. Competition between individuals adds little to the survival of the species. Species become extinct not because they kill each other off but because they fail to adapt to a changing environment. Intraspecies competition is secondary.

According to Kropotkin, peace and reciprocal support are the rule within the group. Because societies or bands were the first social organizations in human evolution, they are the origin of consciousness, the source of social conscience, the innovators of ethics, the originators of the best of religion, gods, and our humanity. The sharing of resources necessary for life precedes all other systems of distribution. Reciprocity is the foundation of our common identity; the community precedes the individual. The life of the community becomes the validation for the life of the individual. Self-sacrifice in all major truth-seeking or sacred systems is the source of the greatest joy for the individual.

Sympathy and self-sacrifice are positively vital to human shared advantage for improvement. Sense of suitability versus hard-heartedness is the starting point of human unity. Mutual aid everywhere can be seen as the dawn of the human spirit and the soul of our humanity. The quest for power is also part of the human condition. With intelligence, conscience needs to be learned. The will to power and the quest for wealth by individuals everywhere undermines community and solidarity. Democratic communism is replaced by a stratified society based upon coercion, exploitation, and oppression. Popular democratic uprisings are as old as class society.

Social instincts are based on the pleasure of companionship; the collaboration of others is the primary basis of ethics. Compassion is the starting point of public service. The public good is expressed in the dialogue of mutual aid. The guide to action is always moral self-control and reciprocal support.

Kropotkin begins by asking the origin and meaning of social ethics. To him, exploitation is caused by unacceptable wealth based upon the poverty of others and is intolerable. Poverty is the direct result of wealth. It is the poor who support the rich through their hard work. This planet has the capacity to feed, clothe, and house every human comfortably. But, the problem must be attacked. It is important to know what is possible and to understand the right thing to do. Where science and ethics come together is the realm of sociology (anthropology).

Freedom and necessity join, and agency becomes action founded upon information. Liberty, based upon knowledge of the essential principles of nature, is the source of sovereignty. Needs and determinism are the sources of free will; people have true choices only if they have the proper knowledge of how to act to lessen unexpected consequences.

In Kropotkin's view, ethics ultimately does lead to fulfillment, for satisfaction comes from the abandonment of exploitation and oppression. Harmony between the individual and the community is this instinct of sociality. Through imagination, we are able to feel what we have never experienced and identify with the joys and sorrows of others. This strengthens our individual identity by morally connecting us with others. Individual initiative grows out of belonging to a community. Each unique individual works together as part of a group to develop strategies for the welfare of all. This is the starting place for the expansion of the individual personality. Moral courage is the first step to overcome passivity—breaking with the narrow philosophies and religions of the past. Fulfillment comes through mutual aid and egalitarian self-restraint. Conversely, economic individualism and personal salvation are the bedrock of narcissism and existential isolation.

K-T Boundary

The Cretaceous-Paleogene (K-Pg) boundary, dated about 65 million years ago, marks the base of the Paleogene period and consequently of the Cenozoic era. ("K" is traditionally used as an abbreviation for the Cretaceous period (from the German term *Kreide*) in order to avoid confusion with the abbreviation "C" of the Cenomanian epoch and the abbreviation "C-T" of the Cenomanian-Turonian boundary.) It is more popularly known as Cretaceous-Tertiary (K-T) boundary, but the term *Tertiary* has become informal and is not used in the geologic timescale. From the chronostratigraphic point of view, the K-T (or K-Pg) boundary was formally defined at the base of a dark clay bed at the El Kef stratotypic section (Tunisia). This bed is commonly called the *K-T boundary clay,* and its basal part is characterized by a millimeter-thick reddish layer, called *K-T airfall layer,* containing meteoritic impact evidence such as anomalous-concentrated iridium, siderophile trace elements in chondritic proportions, microdiamonds, nickel-rich spinels, shocked quartz, and altered microtektites.

The K-Pg or K-T boundary is widely known, because it represents one of the five major mass extinction events recorded in the earth's history, which affected the most famous paleontological group, the dinosaurs. However, the dinosaurs were not the only victims of this biotic catastrophe. It is considered that 75% to 80% of then extant species were extinguished; this included the total extinction of dinosaurs (*Tyrannosaurus, Triceratops,* and *Ankylosaurus* among others), plesiosaurs, mosasaurs, ichthyosaurs, primitive birds (*Enantiornithes, Hesperornithiformes*), ammonites, belemnites, rudists, and orbitoid foraminifers. Many other groups were severely affected, such as mammals (~80% extinguished), osteichthian fishes (~96%), nautiloids (~50%), gastropods (~80%), bivalves (~60%), brachiopods (~70%), scleractinian corals (~80%), thermospheric ostracods (~75%), planktic foraminifers (~96%), radiolarians (~85%) and calcareous nannofossils (~75%). Marsupial mammals became extinct except for those in Australia and South America. Remarkably, insects, amphibians, lepidosaurs (lizards, snakes, etc.), crocodilians, turtles, and insectivore mammals and birds were not very affected by the K-T extinction. Moreover, although their populations were initially decimated, many species of terrestrial plants and of marine phytoplankton (diatoms or dinoflagellates) also tended to survive, due surely to their capacity to form resistant cysts, spores, or seeds.

The K-T extinction was therefore selective, with a species' survival depending on its position in the food chains. In the open ocean, the food chain is and was based on the microscopic phytoplankton (unicellular algae), such as coccolitophorids (calcareous nannoplankton), dinoflagellates, or diatoms. The marine protozoons and animals at successively higher levels in this food chain (phytoplanktivorous and carnivorous) were very strongly affected (planktic foraminifers, ammonites, carnivorous fishes, and marine reptiles such as plesiosaurs, mosasaurs, and ichthyosaurs). However, those animals whose diet was suspensivorous or detritivorous—or those who lived on these—tended to survive, at least partially (e.g., benthic foraminifers and many bivalves, bryozoans, brachiopods, and fishes). In the terrestrial environment, the food chain is and was based on plants, so the herbivorous and carnivorous animals directly or indirectly dependent on this vegetation—all dinosaurs and many birds and mammals—became extinct. On the contrary, those terrestrial animals whose diet was detritivorous (e.g., insects), who were potentially scavengers (e.g., cocodilians, turtles) or insectivorous (ancestral mammals and many birds, amphibians and lepidosaurs) tended to survive.

The most widely accepted theory for explaining the K-T mass extinction event is the meteoritic impact theory proposed by Luis Alvarez (1968 Nobel Prize winner in physics), Walter Alvarez, Frank Asaro, and Helen Michels in 1980. They discovered a reddish-greenish sedimentary layer at Gubbio (Italy) that marked the boundary between Cretaceous and Tertiary sediments, and it contained an anomalous concentration of iridium—hundreds of times grater than normal. Iridium is extremely rare in the earth's crust but abundant in chondritic and iron meteorites. For this reason, Alvarez's team proposed that a collision with a large asteroid (about 10 kilometers in diameter) caused the K-T extinction event 65 million years ago and the deposition of the reddish-greenish layer or airfall layer at Gubbio. Almost at the same time that Alvarez's team proposed this collision, Jan Smit suggested the same theory after studying the Caravaca section (Spain), which was a more expanded and continuous section than that at Gubbio. He proved that the airfall layer coincides with the largest, most sudden planktic foraminiferal mass extinction in evolutionary history, suggesting a clear relation of cause and effect between the impact event and the K-T catastrophic mass extinction. Since then similar airfall layers have been found at sections worldwide, such as the El Kef section, suggesting the totality of the K-T event.

The discovery of the ~180-kilometer-diameter Chicxulub crater on the northern Yucatan Peninsula (Mexico) supported strongly the Alvarez group's theory, because such a crater was coincident in age with the K-T boundary and has just the size to have been formed by the predicted 10-kilometer-diameter meteorite. In addition, strange and thick K-T clastic sediments were discovered around the entire Gulf of Mexico, suggesting the destabilization of continental margins in the region as result of giant tsunamis and earthquakes generated from the impact point at Yucatan.

Most geologists and paleontologists agree with Alvarez's impact theory, although alternative scenarios have been suggested for explaining the K-T extinction. They include sea-level regressions, increases of the volcanic activity linked to the Deccan Traps (an extensive basalt province in India), or multiple causes, that is, all the aforementioned causes operating at the same time. However, these hypotheses have not been accepted by the geologic and paleontologic communities, because they would be more compatible with uncorroborated gradual extinction patterns occurring hundreds of thousands of years before and after the K-T boundary.

According to Alvarez's theory, the impact raised a vast dust cloud of fine ejecta in the atmosphere and triggered global firestorms due to the fall of incandescent melted fragments worldwide (tektites and microtektites). The dust and soot cloud generated a global atmospheric darkening, sudden climatic cooling and acid rain, a phenomenon known as "impact winter" (similar to a nuclear winter). The blockout of sunlight caused the cessation of all photosynthesis and the severe disruption of food chains, initiating the catastrophic mass extinction event at the K-T boundary. The dust and fine ejecta that covered the atmosphere after the Chicxulub impact were deposited slowly, probably over months or a few years, forming the K-T airfall layer worldwide.

Atmospheric carbon dioxide content increased rapidly as result of the emissions from the impact site and the widespread fires as well as the temporary cessation of photosynthesis and primary productivity. After the dust cloud settled, the high concentration of carbon dioxide initiated a greenhouse effect period that lasted about 10,000 or 15,000 years. The K-T boundary clay was deposited during this period of global decrease in primary productivity and of increased greenhouse effect after the impact winter. All postimpact paleoenvironmental aftermaths of longer term (decrease in primary productivity, low biodiversity, greenhouse effect, disruption in the water column stratification, etc.) have been recorded in the K-T boundary clay worldwide. Only the most cosmopolitan, generalist, and opportunistic species were able to survive the environmental damage of both the impact winter and greenhouse effect periods.

Terrestrial plants and marine phytoplankton, and consequently primary productivity, recovered progressively over thousands of years, reestablishing the food chains and decreasing the concentration of carbon dioxide in the atmosphere. Many niches remained vacant after the K-T mass extinction, so the opportunistic surviving species began to occupy them. Small and new marine and land species appeared in the earliest Tertiary, following a model of "explosive" adaptive radiation. For instance, mammals diversified, evolving from the small insectivorous mammals that had survived the K-T event and becoming dominant on land. Similar adaptive radiations occurred in other marine and terrestrial groups. Thanks to the K-T extinction of the dinosaurs, the mammal groups could diversify during the Tertiary, including those that formed the evolutionary lineage of the primates that culminated with the appearance of the species *Homo sapiens*.

Kuhn, Thomas S. (1922–1996)

Thomas S. Kuhn is recognized as one of the foremost historians of science to have emerged in the 20th century. He is credited with a controversial approach to understanding scientific development, one that emphasizes rare but significant revolutions that challenge and even overthrow traditional ways of observing the world. Such revolutions, he claimed, change our views so profoundly that it may be unreasonable to compare theories that originated in different times. It is unfair, for example, to judge the writings of Aristotle (384–322 BCE) according to the standards of proof required today, not only because Aristotle could not have been aware of the scientific discoveries since his time, but also because the ancient Greeks understood worldly phenomena according to a different set of guiding principles. The scientific revolutions of more than 2000 years have rendered our perspectives beyond comparison; Kuhn calls this the "incommensurability thesis."

Paradigm Shifts

Kuhn studied physics at Harvard before teaching the philosophy of science at a variety of schools (most recently Princeton and MIT). His book *The Structure of Scientific Revolutions* (1962) inspired intense controversy by calling attention to the limitations of accepted scientific methodology. Kuhn wrote that science, or rather scientists, proceed through time operating according to a collection of accepted theories. There are few challenges to these theories, because they are assumed to reveal truths about the world. Because the scientific method has already exhaustively tested such explanations, any new work by scientists is expected to conform to accepted laws and principles. Occasionally, however, the conventional knowledge base is unable to answer a particular problem, or worse, it is at odds with a new theory or observation. When a solution emerges that resolves such a crisis by overthrowing previously accepted elements of scientific knowledge, then what Kuhn calls a *revolution* has occurred.

The term *paradigm shift* originated with Kuhn's vision of a scientific revolution that interrupts the normal thought paradigm. The traditional view of science presumes continual progress as advancements contribute to an ever-growing base of knowledge. When theories are revised and formerly held principles abandoned, then science simply has witnessed a correction that brings us closer to an underlying truth. Kuhn rejected this traditional view. Instead, he claimed that there are long periods with negligible progress, what he called *normal science* (operating within conventional knowledge) that are occasionally punctuated by revolutions. There *is* monumental progress in science, Kuhn would claim, but only through the process of alternating eras: convention, revolution, convention, revolution, etc.

Scientists might pursue monumental innovations (e.g., inventions, discoveries, cures for diseases), but they are held back, Kuhn claimed, by the prevailing wisdom of the time. In other words, the tendency is to think *inside* the box. This urge for innovation, restrained by conventional thinking, Kuhn referred to as *the essential tension.* In his view, revolutions are not actively sought. Instead, changes in thinking occur as a matter of necessity when accepted principles are replaced by the new paradigm. Advancement has less to do with individual accomplishments than with new modes of thinking that are so profound that they render obsolete some aspect of the former status quo. If science consists of games or puzzles, then there are familiar rules under which we attempt to solve problems. A true paradigm shift introduces not just a new puzzle to be solved, but new directions for answering old questions. The new theory not only resolves some inadequacies of past thinking, but also launches a new set of problems and guidelines for proceeding. Kuhn was not suggesting that individuals strive to overthrow established consensus. Rather, he was describing a cycle of convention, crisis, revolution, and new convention.

Evolutionary Science

To Kuhn, this theory was not just for the history and evolution of frameworks in science; science itself is evolutionary. When science meets with the hostile environment of an unsolvable problem, adjustments are made to address the challenge. In the traditional view of science, competing theories battle against one another; through the trial and error of the scientific method, the strongest theory emerges victorious and progress is claimed. For Kuhn, however, the competition pits the existing body of scientific knowledge against conflicting ideas; challenges to the standard way of thinking are discredited by conventional scientists, because their operating principles are regarded as truths. If a sufficient number of scientists present the same new idea over time, or especially if a new idea successfully resolves a major problem that has plagued science for a very long time, then that new idea might be paradigm shifting.

In embracing the revolution, the evolutionary change is dramatic. Where traditional science would (reluctantly) accept new information as an addition to the growing body of knowledge, however, Kuhn emphasized that some old theories, instead, are discarded to make way for the new. In organic evolution, fins are replaced with limbs, not augmented by them; it is absurd to imagine a creature that collects and maintains every feature its ancestors have ever possessed (the platypus notwithstanding). To continue the analogy, Kuhn saw revolutionary science as changing significantly enough that appendages are no longer recognizable. Traditional science, like Darwin's original conception of evolution, envisioned a series of continual changes over time. To recognize biological evolution as a series of periodic responses to catastrophes, however, is more akin to Kuhn's vision: Scientific revolutions are reactions to intellectual crisis, but they are rare.

The conventional view of science, according to Kuhn, is mistakenly teleological; it presumes that scientific inquiry is progressing toward a particular goal. The principles originally developed through the observation of patterns in nature have been elevated to such esteem that they are taken as truths about the world or, in any case, as steps toward eventually knowing an objective and unchanging Truth. Just as evolutionary adjustments might be arbitrary, though, responding as they do to challenges posed by the external environment, in Kuhn's view scientific advancement is vulnerable to sociological influence. History has shown that political bias sometimes keeps science at bay: Followers of Copernicus were convicted of heresy for daring to support his theory of heliocentrism (e.g., Giordano Bruno was burned at the stake; Galileo Galilei was placed under house arrest). Indian astronomers as early as the 7th century BCE (and ancient Greeks 300 years later) had believed the earth to rotate around the sun, yet religious influence prevented acceptance for centuries. Like the Connecticut Yankee, regarded as a magician for his demonstrations in King Arthur's court, scientific knowledge is contingent upon a particular era in time.

Kuhn's view of the history of science recognizes that what passes for "knowledge" is subject to revision and conventional science restricted by its own parameters. The scientific timeline is neither static nor perpetually expanding as we endlessly acquire new knowledge. Paradigm shifts are so radical it is inappropriate to hold theories from one era to the standards of another. According to Kuhn, true scientific advancement replaces obsolete principles with new ways of thinking that revolutionize our view of the world.

L

La Brea Tar Pits

The La Brea Tar Pits, or Rancho La Brea, are a famous group of tar pits located in Hancock Park in the heart of downtown Los Angeles, California. This location contains one of the richest and best preserved assemblages of fossilized Pleistocene life in the world. The plant and animal remains found represent hundreds of species that populated southern California from almost 40,000 to 10,000 years ago. Rancho La Brea provides a wealth of information on life during the most recent ice age.

Tar pits form in places where crude oil seeps to the surface of the earth through cracks in the bedrock. A portion of the oil evaporates, leaving thick, viscous pools of asphalt behind. Local natives used this resource for thousands of years to waterproof baskets and canoes. As Caucasian settlers moved into the area, the tar was collected and used for roofing in the nearby town of Pueblo de Nuestra Señora la Reina de los Angeles.

A family named Hancock owned and worked a 4,400-acre ranch that encompassed the tar pits in the late 1800s and continued to mine the pits for tar to use as a sealant. Occasional bones unearthed were assumed to be those of cattle that strayed, got stuck in the tar, and perished. Eventually paleontologists heard about the bones and performed the first scientific excavation in 1901. Work intensified as the number of finds increased. From 1913 to 1915, digging at over 100 pits produced more than 1 million bones. In 1924, businessman G. Allan Hancock donated the 23-acre plot containing most of the tar pits to Los Angeles County. Early excavators tended to keep only the large, complete bones for museum display. When digging resumed in 1969, more care was taken in cleaning and analyzing over 40,000 additional specimens retrieved.

Tallying and cataloging the bone and plant remains provided insight into the activity around the tar pits so long ago. Wood, plant, and pollen remnants illustrate a cooler and wetter environment than exists today. The park is best known for the large mammals found in the pits, including mammoths, camels, sabertooth cats, dire wolves, and giant ground sloths, but many other species have been revealed. Since excavations at Rancho La Brea began, evidence of more than 650 species has been recovered: 231 vertebrates, 159 plants, and 234 invertebrates. More than 95% of the mammal bones found belong to only seven species. Four were carnivores: the dire wolf, the sabertooth cat, the coyote, and the North American lion, and three were herbivores: the ground sloth, the bison, and the western horse. The most common bones found are those of the dire wolves, with over 2,000 sabertooth cat specimens ranking second. Of the mammals found, 80% were predators, and 60% of the birds were birds of prey. These percentages reflect the exact opposite of what you would expect to find in the wild.

In a stable ecosystem, herbivores always outnumber carnivores by about 10 to 1. The leading theory to explain this discrepancy is called *entrapment.* Asphalt is very sticky, especially when it is warm. Only one inch of this tar can hold a horse or cow until it dies of starvation or exposure. In dry weather, dust can blow across the surface, making the ground appear solid. A trapped animal thrashing around trying to escape would attract the attention of many predators. In attacking the prey, some of the attackers would also get stuck, providing additional food for other carnivores. This cycle repeated for 30,000 years to create the accumulation seen at Rancho La Brea today. Although the collection seems to represent a huge number of animals, it averages out to one herbivore being trapped every decade, and several scavengers attempting to retrieve the meat and joining their prey.

Although thousands of individual animals have been found in La Brea, only one human skeleton has been discovered. The skull and partial skeleton of a Native American woman was recovered in 1914. She was in her early 20s when she appears to have been killed by a blow to the head. Her bones have been dated to about 9,000 years ago.

The La Brea Tar Pits provide a treasure trove of information about life during the late Pleistocene. While studying the bone collection reveals information about ancient food chains, the sophisticated chemical tests available today reveal a surprising amount of detail about how animals became trapped in the tar pits and what happened to them in their final hours of life. The Page Museum in Hancock Park opened in 1977 to house the heritage of over 1 million specimens recovered from the tar. The museum features more than 30 exhibits of reconstructed skeletons and robotic sculptures, a glass-walled working laboratory where visitors can watch the curators work, hands-on displays, films, and many wall murals. Rancho La Brea sheds light on a fascinating time period when glaciers last covered much of the hemisphere.

Laetoli Footprints

In 1976, a trail of fossilized hominid tracks was found in Laetoli, Tanzania. These footprints were determined to be at least 3.6 million years old, and some of the earliest evidence ever found to illustrate upright, bipedal walking in early hominids. Thanks to a chance series of events including a volcanic eruption, a light rainfall, and a second deposit of ash, scientists today can observe firsthand the preservation of a specific moment in prehistoric time.

Laetoli was first surveyed by anthropologists in 1935, when Louis S. B. Leakey and his wife Mary D. Leakey evaluated the area. They were excavating at Olduvai Gorge 2 days to the north when Maasai tribesmen told them there were many bones at Laetoli. The team investigated when the Olduvai season ended. After making a few scattered, fragmented finds, they left. Later, during the 1938–1939 season, a German team surveyed the Laetoli area. The Leakeys returned a couple of more times, with few results. In 1974, Mary Leakey found better preserved hominid remains, resulting in a more systematic evaluation of the area. One night in 1976, team member Andrew Hill was joking around with colleagues, throwing dried elephant dung in a mock battle. As Hill ducked to avoid a hit, he noted what appeared to be animal prints preserved in the exposed volcanic tuff. Further investigation revealed a trail of hominid footprints.

The majority of the Laetoli footprint site was excavated in 1978. The exposed trail is about 80 feet long. The prints are distinctively different in size and in two parallel tracks. Despite the size disparity, the strides are the same length, indicating that the two hominids were walking together and compensating to match their strides. Scientists have disagreed as to whether the tracks represent two or three individuals. The smaller prints in the westernmost trail have sharp, clear impressions. The larger prints are blurred and more indistinct. Some argue that a third hominid was walking in the prints made by the larger individual, while others claim the larger, heavier hominid was simply sliding more in the wet ash. The footprints are almost indistinguishable from those of modern humans except for their small size. They have a deep heel impression, a distinct arch, and push off from the toes at the end of the stride. The big toe is in line with the other toes like the toes of a modern human, rather than being an opposing toe like that of a chimpanzee.

Regardless of whether the prints were made by two or three hominids, the importance of this find cannot be overstated. It is, literally, rock-solid proof that early hominids were bipedal long before large brains evolved and stone tools were used. The only hominid fossils found at Laetoli belong to *Australopithecus afarensis,* indicating that individuals of this species made the trail. Despite years of searching, no stone tools have been found in the Laetoli beds, indicating for now that hominids had not yet developed into the toolmaking stage.

Study and debate about the Laetoli footprints is ongoing, but no one can deny the uniqueness of this find. Approximately 3.6 million years ago, the Laetoli area was savanna that supported a varied animal population. At the beginning of a rainy season, Sadiman, a volcano to the east, erupted. The shower of ash was not severe enough to drive the animals away. The season brought intermittent showers, turning the ash to a fine mud that the local fauna continued to walk through. Several times over the course of a few weeks additional light layers of ash covered the area. The scattered rains continued to make a mud that left distinct impressions. Finally a heavy ash fall buried the area deeply, protecting the Footprint Tuff from erosion. Over time, the ash cemented and became rock. Weathering eventually brought the Footprint Tuff layer to the surface again, giving modern man a unique view of a specific event in the life of early hominids. A brief moment in prehistoric time has been preserved.

Lamarck, Jean-Baptiste de (1744–1829)

During the latter half of the 18th century, a handful of science-oriented enlightened thinkers took time and change seriously; they saw history in terms of process and progress. Jean-Baptiste de Lamarck extended this perspective to become the first serious evolutionist. He argued for the mutability of animal species over vast periods of time, in an age when most other naturalists still maintained the fixity of life forms on a planet held to be only several thousand years old. As an invertebrate paleontologist, he took the fossil record in the geological column as empirical evidence demonstrating the evolution of species, into life forms of increasing complexity and greater perfection, as seen in their preservation up through the rock strata. Lamarck presented this controversial view of organic history in his major work, *Zoological Philosophy* (1809).

Lamarck's evolutionary interpretation of life was in sharp contrast to the one offered by the contemporary vertebrate paleontologist Georges Cuvier, who held that the fossil record (with its gaps) represented a history of periodic creations and extinctions. Cuvier's vision suggested a series of divine creations, each special creation eventually followed by worldwide extinction due to a planetwide catastrophe. Thus, Cuvier was not an evolutionist. However, Lamarck saw the biological continuity of species (without any extinctions) throughout organic history. Because evolution challenged the entrenched beliefs in the biblical story of Creation in the Book of Genesis, with its 6 days of Creation, religious naturalists were not open to Lamarck's new worldview, despite those ongoing discoveries in geology and paleontology that clearly supported an ancient earth and the mutability of species on it, respectively.

Lamarck held that spontaneous generation would explain the sudden appearance of the first forms of life on earth. But, the fossil evidence to the contrary, he needed to account for the evolution of species over considerable time. Lamarck offered two explanatory mechanisms: the inheritance of acquired characteristics through use and disuse, and a form of vitalism that manifested itself only in complex animals. Lamarck's famous but now notorious example to demonstrate his first explanation involves the evolutionary history of the giraffe. He held that, eons ago, short-necked giraffes fed on the leaves of eye-level trees. Over time, these trees continuously became taller. Consequently, in order to reach and eat the ever-higher leaves, the giraffes needed to constantly stretch their necks. This acquired characteristic of a longer neck (due to continuous stretching) was inherited by the offspring over numerous generations. The ongoing accumulation of this useful and specific characteristic has resulted in the long-necked giraffe of modern times.

Furthermore, Lamarck speculated that complex animals with consciousness could actually will those characteristics (structures and functions) that they needed or desired in order to adapt to, and survive in, changing environments; he even thought that, through willing, new organs and behavior patterns could emerge over time. Not surprisingly, because of a lack of convincing experimental evidence, naturalists have not accepted as true Lamarck's two explanatory mechanisms for the evolution of life on this planet.

Concerning the origin of our own species, Lamarck boldly claimed that the human animal had emerged from an orangutan-like primate somewhere in Asia. Through slow evolution, he maintained, our human species gradually acquired those mental faculties and biological characteristics it has today. Moreover, Lamarck argued that humans differ from the living apes and monkeys merely in degree rather than in kind; the superiority of human reason is grounded in the larger and more complex brain of our species. However, the present fossil record points to Africa as the cradle of humankind. Even so, modern primatology does clearly demonstrate the striking similarities between the human animal and the great apes.

Lamarck died blind and poor, unaccepted and unappreciated by most of the naturalists of his time. Nevertheless, he was a significant link between the ideas of earlier natural philosophers, who held to the fixity of species, and those pivotal scientific writings of Charles Darwin that presented the mutability of life forms in terms of organic evolution by natural selection. In fact, Darwin's *On the Origin of Species* (1859) appeared exactly 50 years after the publication of Lamarck's *Philosophy of Zoology* (1809).

Language

> We look back at the thoughts of our predecessors, and find we can see only as far as language lets us see. We look forward in time, and find we can plan only through language. We look outward in space, and send symbols of communication along with our spacecraft, to explain who we are, in case there is anyone who wants to know. (David Crystal)

Among the most popular areas of study that involve explorations to characterize humankind is the study of language. Throughout history, individuals have been fascinated about how language works and even more by the unique characteristics of each language as well as the common ones among the languages of the world. The phonology of different languages is especially interesting to some researchers; others are intrigued by grammar and morphology that show similarities in structure among languages. Some find great satisfaction in studying expressions of idiom, metaphor, and humor; others look to how societies function and get along as they adjust their language use for communicating in specific environments (e.g., formal or casual). Whatever the intentions or goals of those who study language, that this field of endeavor has endured for thousands of years attests to the changing nature of language over time, wherein there is always something new on the horizon to try to understand.

Definitions of Language

Although there are some distinct characteristics that are used to identify languages (e.g., phonology, grammar), definitions of *language* and *languages* vary among scholars depending upon their particular curiosity and the questions for which they want to find answers. Joel Davis comments that there is somewhat of a dilemma for linguists to capture all of the characteristics into one definition. How does one describe language incorporating the terms of the language he or she uses? It is like defining a word by using that word in the definition. Thus, many researchers attempt to compare human languages in order to find common components and to identify differences, hoping such pursuits will add to the specificity of the term. Language definition is somewhat like trying to hit a slowly moving target, because there are many factors of language that gradually change as societies change. Abram de Swaan proposes that a language may be defined by the capacity of any two speakers to understand each other and incidentally notes that the variety and complexity of languages is such as to be comparable to that of life itself.

Studies about language can be separated from studies about the history of humankind only by an imaginary line that has to be crossed quite regularly. Definitions of language have to allow for distinctions that influence it from other areas of human evolution, such as the development of communities, trade, music, and art (in themselves kinds of language).

The Generative Nature of Language

If one were to converse with thoughtful individuals about their native tongues, one would probably find out that they agree that their own language is not static but rather is creative and permits new and adapted forms of words and expressions as the times require them. As societies and communities progress and as educational opportunities grow, so does the mother tongue. But, in some cases where there is little progress, languages become endangered and sometimes extinct. Technological terms, for example, not occurring in the first few decades of the 20th century are now part of many languages of the world: the word *computer,* for example, appears in French as *l'ordinateur,* in Japanese as *keisanki,* and in Maori as *rorohiko*. Contrastively, languages among hunter-gatherer tribes in Africa, as explained by Lenore Grenoble and Lindsay Whaley, are more threatened by extinction than those spoken by groups that are involved in socioeconomic reorganization and growth.

Spoken Language Over Time

Linguists recognize that amidst the intricate web of factors involved in language change, modifications in sounds and vocabulary seem to lead the other stages, particularly grammar, even though the total process may be extremely slow, occurring sometimes over centuries. John McWhorter discusses how the "erosion" of sounds over time leads to the development of new words, or even of new languages. Consider, for example, McWhorter's description of the movement from the Latin word for woman, *femina* (FEH-mee-nah) to *femme* (FAHM) in French. The accented syllable in the Latin word for woman remained, while the other two weak syllables eventually disappeared. Latin evolved into several new languages, including French, and although it is no longer a spoken language, Latin endures in written form.

Throughout human history, individuals have modified their indigenous languages and have created new words and expressions. For example, William Shakespeare (1564–1616) left an enduring influence on the English language with hundreds of words commonly used today that he created by using nouns as verbs, using verbs as adjectives, and adding prefixes and suffixes (e.g., *countless, bet, laughable, excitement, torture)*. Words are also coined or invented when there is a need for new ones. Among his many malapropisms, U.S. President Warren G. Harding's *normalcy* (for *normality*) continues in common American English usage today. Some novel words endure, and others disappear (e.g., *defidate,* to pollute, circa 1669; *yuppie,* attributed to Bob Greene of the *Chicago Tribune; guillotine,* renamed for Dr. Guillotine who urged the machine's use in the French Revolution).

Language Mixtures

Although the grammars of spoken languages are rather stable, bound by rules, and slow to change, they may be affected by the incorporation of new expressions, especially in those societies whose members may have come from nations with different mother tongues. Such is the case in the United States, considering the large waves of immigration from the mid-1800s to the 1920s. As first and second generation children of immigrants from Western Europe and Asia learned English, they adopted accommodation behaviors, or *interlanguage* for communicating appropriately in places in their communities when their English was not yet fluent (e.g., at the store, in mixed ethnic neighborhoods). An interlanguage is defined in one of two ways. It may be the way that one individual, still learning the language of a society different from one's own, creates novel terms or mixes terms between one's language and the target language. A Polish immigrant might say something like, "*Ja będę iść do marku*" ("I will go to the market"), substituting the English word, *market,* for the Polish word, *rynku,* but retaining the final letters from the Polish word.

A second characterization of interlanguage regards the reciprocal relationship in communication between two individuals with distinct mother tongues. In this case, each individual accommodates the other in clever verbal manipulations. The use of interlanguage may continue among speakers for considerable time, or it may eventually lose its utility once the speakers become fluent in a single new language. Larry Selinker provides an example of an Israeli who continued to produce English sentences of the type, *I bought downtown the postcard,* even as a fluent bilingual in Hebrew and English.

Quite often, when individuals become bilingual, they switch between the two languages in their attempts not only to be understood but also to clarify for themselves what they mean. This behavior, called *code switching,* has been studied extensively by sociolinguists for spoken language as well as written language where it also might occur. Over time, accommodations such as interlanguage and code switching influence the development of new words and expressions in the main target language.

A special case where factors such as code switching and interlanguage are especially helpful for understanding language growth is manual language, particularly sign language that is used by deaf communities. Of over 100 such sign languages used throughout the world, the most studied is American Sign Language (ASL). Because of the efforts of William C. Stokoe in the 1960s, ASL gained recognition as a true language. Researchers have since explored all facets of the language to support its identity. Sociolinguistic research into ASL continues into the 21st century to identify characteristics that are equivalent to those found in spoken languages. Besides the areas that concern formal linguistics (i.e., phonology, grammar, semantics, pragmatics), research is now replete with studies regarding code switching and pidginization. Research about social interactions within deaf communities and between deaf individuals and hearing individuals has been most fruitful.

Code switching and interlanguage are relatives to a language dynamic known as *diglossia.* This occurs when members of a community recognize that there are varieties of their mother tongue that have to be selected for particular situations, such as a more formal variety for the business world, or for worship or governmental meetings. These varieties may differ in grammar as well as word usage. Joshua Fishman explains that diglossia can also involve two distinct languages (e.g., Latin in some Roman Catholic Church services, but a native language outside of church).

Language varieties are special forms of language that endure within speech communities, and they may have taken a long time to establish (e.g., formal French and vernacular French). Often, a more formal variety is one that is used in written literature, while the less formal variety will never be used in writing. What is interesting about diglossia is the existence of two or more varieties of a language, side by side, that do not eventually mix. This is not the case, however, with pidgins and creoles.

Pidgins and Creoles

Pidgins are formed when individuals who speak two different languages create a means for immediate communication that involves the integration of characteristics of each of their languages. Most pidgins endure only as long as they are needed for a particular purpose, but some, such as *Tok Pisin* of Papua New Guinea, remain as a common vernacular. Historically, pidgins have developed throughout the world, with many used predominantly in areas where trade necessitated communication between European traders or colonizers and native people. These "half-languages," as John McWhorter calls them, can occur any time when conditions warrant it between speakers. Although pidgins do have limited rule systems, they do not qualify as natural languages even though some pidgins endure and are expanded over time so that they have all the typical characteristics of a true language.

In some societies, pidgin languages have undergone a process of change from one generation of speakers to the next so that they become the mother tongue, or more appropriately, a vernacular. These new languages are called *creoles,* taken from a Portuguese term that describes persons of European descent who were born and have lived in a colonial territory. The process by which a pidgin becomes a creole is known as *creolization.* It involves the stabilization of grammatical rules and vocabulary that allows for language generativity and novel use, similar to that in natural languages. McWhorter explains that that there can be varieties of a creole language, somewhat as on a continuum. Individuals may show flexibility for using a creole language in more than one variety depending upon the circumstances and needs of a particular communication.

More Evidence of Language Change

Another set of characteristics that are evidence of language change include dialects, jargon, slang, and colloquial expressions.

Dialects are forms of language that involve pronunciation, vocabulary, and grammar that differs from what is designated as the standard form of a language. The origins of dialects vary. The language, Icelandic, for example, began as a dialect branching from Proto-Germanic, the precursor of the Germanic line of languages in the Indo-European language tree. Sometimes dialects have developed within groups of individuals that live apart from a larger society; sometimes they have developed over time in a geographic region that has been influenced by the merging of linguistic elements from two or more varieties of languages. People of the Appalachian Mountains speak a dialect that was influenced by varieties of English from Scotland as well as England.

The term *dialect* may also be used as an equivalent term to describe a language. Many Chinese languages are called dialects (e.g., Oirat dialect, a Mongolian language), as are some creoles.

Dialects are many times erroneously identified solely by speech patterns. They are likewise mistaken in many instances as having to do with one's social status. Historically, Americans in the northern states have judged individuals from the south with significant bias due to their dialects. As access to communication media becomes more common, bringing people of all walks of life together on a daily basis, these biases are weakened in America.

Slang and jargon provide evidence that languages can change with the influence of individuals who might be assumed to have little or no effect upon how the majority will continue to speak (e.g., adolescents). Robert MacNeil and William Cran, recounting what they learned about Californian *surfer dude* speech from the writer George Plomarity, explain that it is not actually uncommon for slang expressions to take on formal use over time. For example, someone who works in a law office might comment that he is *caught inside,* meaning in a situation that cannot be avoided where a great amount of information and interactions are coming in all at once (just like waves of the ocean).

Language Adaptations and Language Continuance

Because one of the main goals of humans is to interact with other humans, it might seem obvious that language adaptation would be relatively common. And, individuals frequently do adapt their language to facilitate communication, sometimes creating pidgins or using interlanguage, for example. Over time, what started out as an adaptation may show novel and somewhat permanent changes within existing natural languages, or new languages such as creoles might evolve. Yet, considering the tendency of societies to grow and change, access to certain language forms might also be limited to specific groups of people within a community. Sociolinguists have documented barriers to communication in thriving as well as developing nations and societies in the world.

Abram de Swaan, a political sociologist of language, envisions the world as a complex language system, a galaxy constituted of a global constellation in which there are major star patterns determined by factors identified in social science theories (e.g., trade, economics). As do many sociolinguists, de Swaan points out that language can be used as a tool for isolation and for insulation of groups of people. It can be manipulated to keep individuals from participating in specific areas within a society as well as enabling individuals to bond with others. For example, literacy continues to be prohibited to women in certain societies. Contrastively, interlanguage or pidgins can open up communication between peoples with different indigenous languages for the sake of commerce.

In some nations it may take a concerted act of the leaders within a society to establish venues that will help to keep a native language viable and to generate new words and expressions that are necessary for communication in subjects and categories that may influence a nation's growth. It may be a matter of pride among the people themselves to try to maintain their native tongue. Fearful of the demise of their lingua franca, Ewe, the people of the small country of Togo took measures to develop terms such as those needed for technology and new forms of commerce. Once a French colony, the Togolese Republic uses French as an official language, but it strives deliberately to keep its indigenous tongue, Ewe, alive. There is also a considerable body of literature written in Ewe, and this is helpful for sustaining the language.

Written Language and Literacy Over Time

The provision of a written form of a spoken language tends to support the viability of that language. Although this is so, forms of written language and literacy have not always been available to all classes or groups of people in societies from the time of their invention. Literacy was used as a tool for economic and political power in ancient civilizations, and this continues even to the present. Fishman describes the nature of literacy as "a sociocultural phenomenon in its own right, thus subject to many of the same political and self-interest concerns which come into play when making a language/dialect decision."

Alice Joan Metge documents this situation in her history of the Maori of New Zealand. Up until the mid-1800s, most of the Maori had maintained their native tongue and had established a base of literature. Those in power at that time, however, developed language-planning goals insisting upon the use of English in the community and as the only language in schools. Children were punished for using the Maori language even into the 1960s. At the beginning of the 20th century, some 90% of Maori children knew their indigenous language, but by 1953–1958, this number had dropped to 26%. Families also contributed to this loss. They recognized opportunities for their children if they used English. Thus, instead of creating terminology for industry and commerce in the Maori language, communities used English words and spoke for the most part in English. In the early 1970s, the Maori Youth Movement was successful in convincing the government to support efforts to revive the Maori language. The Ministry of Education adjusted the school curricula for children, and courses were offered in Maori up through the university level. Maori became integrated in many venues in society. Now, Maori terms and expressions necessary for daily life have increased in number and are not treated as novel. In the 21st century, New Zealand continues to celebrate Maori Language Day and has week-long activities to encourage pride in the native tongue. Literature is thriving and programming in Maori is available on the Internet as well as on local television.

The situation of the Maori is not unique. Fishman explains that as communities strive to modernize, the development of literacy involves their statement of economic, political, social, and cultural power. The leadership elite who may have had exclusive command of literacy will not necessarily be satisfied to permit the common person the capability to acquire it and join them in acts of literacy. Yet, literacy, just like spoken language, is growing relatively rapidly in developing as well as established nations.

Considering literacy in Europe, Fishman cites research that indicates there were only six languages of literacy by the year 950 (i.e., Latin, Greek, Hebrew, Old Church Slavonic, Arabic, and Anglo-Saxon). At the beginning of the 20th century, there were 31; by 1937, 56. By the late 1980s in Western Europe only, there were 67 different languages used in schools and adult education to teach literacy. In all Europe by 1989 there were at least some 200 languages. Fishman estimates that in the 20th century alone, the languages of literacy in Europe increased sixfold. As of 2003, he sees the same kind of dramatic growth in countries in Africa and Asia.

It appears to make sense that a spoken language will survive if its speakers have access to that language in writing. As in the case of Maori, that may be true. There is another direction, however, that some languages take where they appear to be on the verge of extinction in spoken form. A literary tradition of the language may develop and survive beyond its conversational utility.

One language that falls into this group is Picard, a language recognized by Belgium as an indigenous language and acknowledged as a language by the European Bureau for Lesser Used Languages. Although it is very similar to French in many respects, France considers it separate from French, and as with other minority languages, does not particularly care to recognize Picard as a "good" language. Picard is spoken in an area near the English Channel, in a northern region of France and in southern Belgium. Linguist Julie Auger explains that by all appearances spoken Picard should be dying, because most of the speakers in larger towns are older individuals, and they do not seem to see the necessity for concerted transmission of the language to the young. In actuality, the French government has given very little support to groups such as the Picards.

On the other hand, Auger has observed that written Picard is, in her words, "varied and dynamic." There were hints of a literary tradition as far back as the 16th century, but it was in the latter half of the 19th century that there were significant numbers of written works in Picard. By the year 2000, literature and a new magazine were thriving, and these works were being read in print as well as on the Internet. In the final analysis, Auger is hopeful that the expanded literary tradition will continue to get readers more involved in Picard and that the French government may enable it to thrive as a spoken language by giving it recognition and support.

Human Languages and Artificial Languages

Early in the 20th century, with the growth of cognitive psychology, the idea of the generative nature of human language aroused the curiosity of scientists regarding the possibility of creating languages with computers that might mimic human languages. If this were possible, then perhaps the computer could act as a bridge among peoples with different spoken languages. The challenge was particularly provocative for individuals such as Marvin Minsky, who, in an important work titled *A Framework for Representing Knowledge,* proposed structures that stimulated thought regarding the duplication of human language in machines.

In order to function as human languages, artificial ones would have to have grammatical rules that a machine could apply at the level of a sentence, and the machine would have to be able to apply inferential reasoning to capture the real, singular meaning of ideas or the multiple meanings of ideas, expressions, and words. For example, how might a computer interpret words for emotions and feelings and distinguish between them as well as indicate variations by degree (e.g., love of a friend versus love of a picture)? How might it deal with the ambiguity that is so prevalent in human spoken languages (e.g., *Bill told John that he loved Mary)?* In other spoken languages, including English, how might a computer distinguish among polysemous words?

Since the 1970s, the field of artificial intelligence has provided several powerful paradigms that in the 21st century are often taken for granted. Minsky's ideas and those of others like himself regarding frames of knowledge have been translated in such schema and models as that of Vinton Cerf's Arpanet, a precursor of the Internet, as well as in scientific applications such as those of Ray Kurzweil, considered a second Albert Einstein by many. Among his myriad accomplishments, Kurzweil has become well known for his print-to-speech reading machine for the blind as well as for his work with voice activated word processing. Cerf, the vice president of Google since 2005, has been called the father of the Internet. He has had a special interest in the field of communication and deafness because he himself is hard of hearing and his wife, Sigrid, is deaf.

Developments in artificial intelligence have enabled mutual understandings among humans beyond that of their distinct spoken languages. These new means for communication are realized in the scientific world as well as in commerce and even in music, another area studied by Kurzweil. Such developments point to the potential for humans to use "invented" forms of language in ways that can add to the growth of civilization and to enable a convergence of knowledge and sharing of cultures among diverse societies around the world.

Language, Evolution of

The study of the origin and evolution of human language is an essential one to characterize what distinguishes humans from other species on earth. Yet this noble and challenging endeavor has been a source of much speculation as well as research as far back as 3,000 years ago. The search for answers to such questions as why language began and how it evolved has provided researchers with a particularly grand puzzle. In spite of recurring fascination about the topic, without sources of direct evidence it has been virtually impossible to verify many theories, to know precisely when language originated and what the first spoken language was like. At some points in modern history there has been great frustration about the directions of the search, and this even led to a moratorium on scientific investigations in 1866 that slowed down research until the late 20th century.

Shortly after the publication of Darwin's *On the Origin of Species,* ideas and speculations about language evolution were so rampant and frequently quite strange that the primary authority regarding language study, the Société de Linguistique de Paris, put a ban on all discussions about the origins of language. It was not until the last decade of the 20th century that renewed vigorous study emerged. Many believe that the presentation in 1990 of a research paper, *Natural Language and Natural Selection* by Steven Pinker and Paul Bloom, inspired the rapid spread of study into the 21st century.

Although one might assume that researchers in subfields aligned with linguistics would have long been in the forefront of the study of language origins and development, this has not necessarily been the case. Many of the most curious have been in fields such as psychology, anthropology, biology, neuroscience, computer science, and archaeology. At the beginning of the 21st century, a number of researchers, including Marc Hauser, Noam Chomsky, Morten Christensen, and Simon Kirby, called for interdisciplinary research to help define the faculty of language and subsequently posit some answers regarding its evolution. The complexity of the subject requires collaborative efforts among specialists from distinct fields who can deal with the important questions together that otherwise in isolation lead these specialists down a narrow tunnel, so to speak, where there appears to be little light at the end.

Defining Language

The term *language* may refer to one of several constructs (e.g., language of music, language of love, computer language, spoken language, body language). Language is a major component in the larger category of communication among humans as well as among nonhuman primates, birds, insects, and water mammals. Characterizing human language, Noam Chomsky wrote,

> The human faculty of language seems to be a true "species property," varying little among humans and without significant analogue elsewhere. . . . Furthermore, the faculty of language enters crucially into every aspect of human life, thought, and interaction. It is largely responsible for the fact that alone in the biological world, humans have a history, cultural evolution and diversity of any complexity and richness, even biological success in the technical sense that their numbers are huge. (Chomsky, 2000)

Studies of communication among species other than *Homo sapiens* have helped to develop a clearer understanding of the unique nature of human language. For example, scientists studying the dance of the bees have identified two characteristics of this signaling system—distance and direction—that help other bees find a source of nectar. In their dance, bees map distance and direction into particular angles and speeds, some greater and smaller, more or less. There is no variation, no modification, of this behavior otherwise.

Joseph Greenberg notes that language systems such as the dance of the bees are iconic. In other words, there is always a one-to-one correspondence between the purpose of alerting for nectar and the specific movements in the dance. Human language, by comparison, is a complex symbolic system with infinite possibilities for generating meaning. Grammar and syntax distinguish human language from the languages of other creatures. Thus, trying to identify the steps through which human language evolved is much more challenging than researching the dance of bees. The search for the origins of human language is a search for a generative and growing system of human exchange between minds and external events, as James Hurford puts it.

Origins and Evolution

The question of where and when the earliest language occurred requires studying the evolution of modern humans from their ancestors, the first hominids (i.e., beings within the taxonomic family, Hominidae). For explorations of human language evolution, it is necessary to consider two realizations of language, gestural language and spoken language.

Gesture

The majority of study regarding the evolution of language focuses upon verbal communication, but a second area of research provides many answers about human language, that is, gestural language. In the latter case, scientists may be concerned with the communicative function of gestures in themselves, or they may be concerned, as is Michael Corballis, with the evolutionary processes of gestural language to speech. He proposes that language emerged from manual gestures rather than from vocalization.

Although there is no documented evidence that early hominids used gestural language, Corballis provides a set of arguments supporting the practicality and effectiveness of gestural communication that may have been used as far back as 25 to 30 million years ago. For example, as an essentially spatial mode of communication, gesturing would provide a silent visual means to alert others about predators or to support the hunting of game.

Somewhere around 6 to 7 million years ago (mya), hominids and apes diverged into distinct groups. At that time, archeological findings indicate, both groups were assumed to have used simple gestures, and both probably vocalized for emotional needs. Hand signals for purposes other than just emotional release are believed to have been used by hominids designated as the genus *Australopithecus,* who are identified by two important characteristics: nonprojecting canine teeth and bipedal locomotion. Because they lacked dental defenses, they needed to develop some way of surviving. Thus, C. Loring Brace postulates that they must have created primitive cultures. This idea is backed up by the discovery of rudimentary stone tools from around 2.5 million years ago. Scientist Ralph Holloway, among others, comments that the early bases for language may have had roots at the time of tool creation and use. Hominids at this time would have had a reason to establish groups for hunting, scavenging, and cooperative living and thus have had a need to develop forms of communication within these groups. Because the hands were no longer needed for locomotion, they could be used for gestures and making tools. These activities could have stimulated the evolution of the brain and especially those parts of the brain necessary for speech.

It seems logical that the early *Homo erectus* would use hand signals and body gestures to communicate. Corballis notes that, given the fossil evidence, by 2 mya the gestures would have been fully syntactic and vocalizations would have been progressively increasing. By 100,000 years ago, early *Homo sapiens* would have used more speech than gestures, but gestures would still have been a characteristic of communication.

Theories about early communication gestures have been most affirmed by those who study manual languages such as American Sign (ASL) or any of the other modern sign languages used by deaf persons in countries other than the United States. Just as research about language evolution and gestures has been slow in developing, it was not until the 1960s that sign language research began to build with studies of the grammar of ASL. The growth of research was due to the work of William C. Stokoe, who provided the foundation for identifying sign languages as true, formally structured languages and not merely cryptic means for communication. Since his time, sign language research has included study within several areas of linguistics, including sociolinguistics and neurolinguistics.

In the field of sociolinguistics, researchers such as James Woodward have established a large body of knowledge of interlanguage communication, studying areas of the world where deaf persons use sign language within their own established communities and/or with hearing individuals. This research is similar to that regarding the development of pidgins and creoles in spoken languages.

What of gestural language among hearing, speaking individuals? Gestures supply visual–spatial support to conversations, enabling a speaker to use emphasis or to demonstrate information that otherwise might take a longer period of time to describe verbally. When there is little or no opportunity to speak, gestures can take on a form of syntax designating meaning. For example, individuals who try to communicate with someone who speaks a language other than their own use hand gestures accompanied by facial expressions and body language in an orderly fashion that parallels their spoken language.

Considering neurolinguistics, much has been learned from the last decade of the 20th century into the 21st regarding language function areas in the brain and sign language. For example, just as do hearing listeners of spoken language, deaf persons show increased activity in the left side of the brain for receptive communication in sign language. Both of the language-mediating areas of the brain, Broca's area and Wernicke's area, are activated when deaf signers watch sentences presented in ASL. Even so, deaf persons show more activity in the right side of the brain than do hearing persons. This has frequently been attributed to the fact that ASL has a distinct spatial component where facial, head, and body movements complement the hand signs.

Philip Lieberman explains that the hominid brain and hand evolved in a precise way that facilitated manual dexterity. He notes that studies in the 20th century comparing the brains of normal individuals to aphasics and those with mental retardation show that there is a link between speech and syntax and motor activity. If that is true, then it makes sense that as the human brain developed, and as the skull and throat developed in the earliest hominids, so too would the use of gestures have developed as well as the growth of spoken language.

Spoken Language

Scientists document that during the Late Pleistocene period that began around 130,000 years ago, brain size in hominids, classified as archaic *Homo sapiens,* had reached modern levels. The increased expansion of the brain is taken as a sign of brain reorganization for language. At the same time, another major indicator of the evolution of humans, the manufacture of tools, shows multiple traditions of stylistic differences across specific regions of the world to which these hominids had migrated. C. Loring Brace explains that these geographic areas are coincidental with the areas of the world that have been mapped for major language families. Thus, he posits that there may be a connection between the development of tools and the development of verbal communication in these geographic areas.

Fossils show that the necessary mouth and throat anatomy for speech were in place even 150,000 years ago. The structure of the human brain and the larynx have evolved so that humans are the only ones who have a low larynx that facilitates speech but that can also interfere with swallowing and be obstructed by food. With this kind of physical structure, it would seem that hominids of the middle Paleolithic era would necessarily cultivate vocalization. Yet, this is a quandary, because other evidence (e.g., hints from unearthed art, burial and living sites, and jewelry) would signal that verbal language did not appear until about 40,000 years ago. This time of social organization and growth is known as the Upper Paleolithic explosion. Most archaeologists would agree that at that time there must have been liberal use of language.

Some scientists believe that there was a sudden cultural shift; others believe the development of speech use was gradual. Just because the hominid anatomy was available for speech, the evolution of the neural pathways may not yet have been ready earlier in time, that is, before 50,000 to 40,000 years ago. Another missing piece of the puzzle is the fact that it is hard to infer without fossil evidence the ways that soft tissue was connected to the anatomy of the vocal tract.

Lieberman believes that speech should have been possible between 150,000 and 100,000 years ago, because there is evidence that the African hominid living during that time had a cranial structure identical to that of modern humans. The tongue was rooted in the throat and not restricted to the vocal cavity, and the larynx had descended. This kind of structure is necessary for rapid and complex speech, and there would be little reason to think that speech might not exist among these hominids. However, their vocal tracts were not completely formed, nor were their abdominal and thoracic muscles that, among modern humans, receive stimulation for speech through the thoracic region of the spinal cord.

Many scientists indicate that there is little evidence about the development of human culture that would support the argument for the necessity of speech before 50,000 years ago. Alternatively, some scientists, such as John Yellen and his colleagues, have discovered signs of a kind of trading network among the Katanda people of Africa, as well as barbed bone, obsidian, and stone used for spear points, and the use of pigments such as red ochre that can be dated between 80,000 and 90,000 years ago. Yellen and his colleagues explain that these archaeological traces may indicate the existence of early societies whose members had modern behavioral potential and hominids with anatomies that resembled those of modern humans. Thus, there may have to be a change regarding the target year estimate of 40,000 years ago for the emergence of speech.

Clues From Written Language

Observations of written language provide clues regarding the existence of grammar and syntax of spoken language as well as changes in these components that signal the difference between human language and that of other species.

Formal Written Language

There is some agreement among scholars that the oldest known formal written language was in use about 5,000 years ago and was probably Sumerian, an extinct isolate language that shows few characteristics common to any of the other spoken language families. There are over 30,000 preserved cuneiform writings in this language as well as evidence from remnants of Sumerian monuments. These show accounts of commerce and politics, culture, poetry, myths, and epics about the origins of civilization in the Fertile Crescent. As a spoken language, Sumerian must have existed prior to being put down in writing. It was spoken in Mesopotamia, in part of what is now modern Iraq, until 2,000 BCE and was supplanted by Akkadian, a Semitic language that like Sumerian is now extinct. The Akkadians, a nomadic people, lived peacefully among the Sumerians until the conquest by Sargon of Akkad, who insisted upon language assimilation. The geographic region continued to use Semitic languages through the time of the Babylonian empire, whose people spoke a dialect of Akkadian. Subsequently, another Semitic language, Aramaic, predominated in the region.

Informal Written Languages

Writing systems that are characterized as representations of informal language lack the consistent use of grammar or syntax. Informal written languages existed as far back as 30,000 years ago. Evidence is seen in cave and other drawings and engravings at burial sites and in artifacts such as jewelry. These forms are found in several key archaeological sites around the world. Although explorations have been made predominantly on the African continent and in the Near and Middle East, one land that has been a source of curiosity about language evolution is Australia. The Aborigines, living in Australia for perhaps 40,000 years or longer, are one people whose ancestors have left a pictorial record across the continent in carvings and paintings representing symbols of life around them, some of these over 23,000 years old. Many of the Aboriginal drawings are in geometric shapes, and they appear to be accounts of numbers of people and events within designated time frames.

It has been estimated that at one time there may have been over 500 spoken languages among 200 distinct groups of Aborigines. These languages show no clear connection to any of the other language families of the world and have been classified by anthropological linguists into 28 of their own families. Currently, in a population of some 400,000, there are fewer than 30,000 who speak one of the remaining 263 original languages. And, it has only been a little over 100 years since outsiders have helped the Aborigines establish a formal written language based upon the visual material that has survived and developed over the centuries. However, there is still much to be learned about these people to put one more piece in place in the puzzle of language evolution.

Language and Future Changes

Recent research in anthropological linguistics as well as genetic linguistics has supported our understandings of the origins, evolution, and current status of languages around the world. Coupled with studies by allied and growing fields such as computer science, biology, and neuroscience, the horizon appears bright, revealing ever more information about language change over time. Linguist Salikoko Mufwene remarks that there is a need for researchers to be open to a variety of alternative assumptions that might advance and enrich current and future thought about language evolution. He states,

> A language is more like a bacterial, Lamarckian species than like an organism. A subset of innovations/deviations in the communicative acts of individual speakers cumulate into the "invisible ecological hand" that produces evolution. . . . There are internal and external factors that bear on language evolution, but they apply concurrently in all cases of language evolution.

Given what is already known about the development of language in humans, it is highly probable that scientific explorations, especially by researchers of several fields collaborating, will continue to reveal subtle as well as vivid evolutionary processes that enable creative and distinct language use among all persons across the earth.

Languages, Tree of

It is estimated that there are between 6,000 and 10,000 living languages in the world. Not all of these languages have been identified and not all have names; not all of these languages will survive in the 21st century. The languages that prevail have done so because of evolutionary processes over vast periods of time. These processes have been characterized and documented by scholars, and all identified languages have been represented using the metaphor of *language families* in schematics known as *language trees*.

Among human languages, there are spoken languages that are indigenous to a geographic area, those that are spoken in places other than the area of origin, and those that are called *official* languages as designated by an official body within a geographic community. There are creole and pidgin languages that developed from contact between two particularly different language-speaking groups, typically a result of trade between Europeans and peoples on other continents, such as Africa. There are language dialects that are sometimes designated as languages, as occurs in China. There are also gestural languages, such as sign languages used by deaf persons. Each sign language has a distinct grammar, syntax, and phonology according to the country in which it is used. It is estimated that there are at least 112 sign languages in the world.

There are many reasons for knowing about the organization and life of human languages. One reason is to support understanding of the history, the current dynamic, and the future of specific cultures and nations. Another is to assist in understanding the role that diversity plays among peoples in the world.

In 1993, the United Nations Educational, Scientific, and Cultural Organization (UNESCO) embarked on a project to find out which languages were viable, endangered, close to extinction, and extinct. As a result of this process, classification schemes for the world's languages were modified, and maps were collected into an atlas that was in its second edition in 2001.

Besides the UNESCO project, the study of the origins of human languages has been especially fruitful from the last decade of the 20th century up

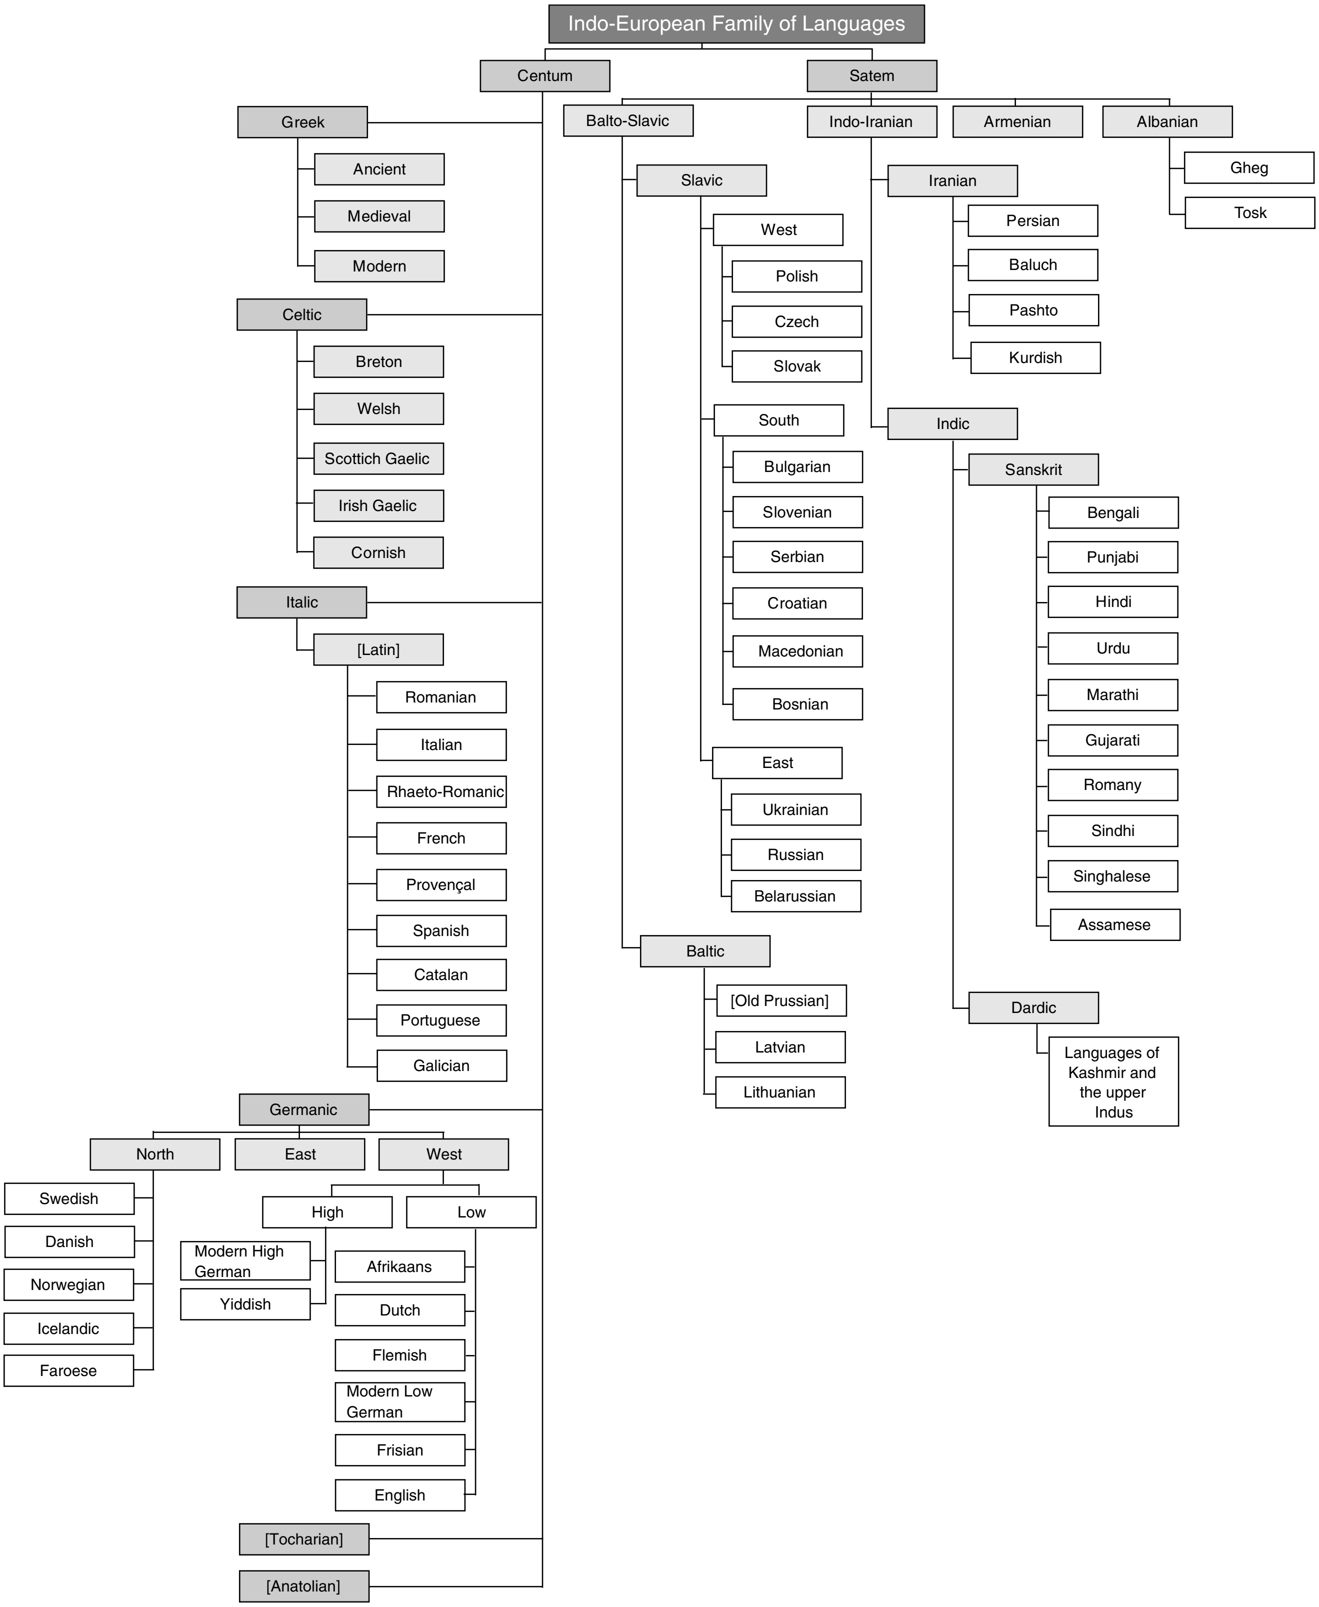

Figure 1 The Indo-European family of languages

to the present, and this research has helped to create schematics for the classification of languages into their particular families. Currently there are 94 different language families in the world whose member languages have been identified by a process called *genetic classification,* where linguists and philologists looked for similarities that showed descent from the same parent language.

Lyovin explains that languages are compared to one another especially for recurring sound correspondences between and among the words of languages that have roughly the same meaning and belong to the basic vocabulary. Each language can be further characterized in relation to other families, constituting distinct *language trees.* The schematic for these trees is usually reversed in a hierarchical format with the main, central family name at the top and the branches extending out systematically below it. For example, there are over 2.5 billion speakers of languages in the Indo-European family, the most studied of language families. This number constitutes 44.78% of the world's people. The Indo-European family tree is divided into two major components, the Centum languages (Western European) and the Satum (Eastern European and Asian). Subsequently, there are branches, such as West Slavic, that then are subdivided into the actual spoken languages of each branch.

Although the Indo-European language family predominates for number of speakers in the world, there are only 430 living languages in this tree. The Niger-Congo tree, however, is constituted of 1,495 living languages that are spoken by 6.26% of all the world's people. Six of the 94 language families account for about five-sixths of the world's population. Among the other 88 language families, there are *isolates:* individual languages with no known connections to any other group of languages. Gilyak, for example, is an isolate language spoken by about 1,000 people on Sakhalin Island and along the Amur River in East Asian Russia. Not every language that is spoken by few individuals is an isolate. Yukhagir is a separate language family of East Asian Russia that is spoken by only 120 people, mostly the elderly, and it is expected to become extinct once these speakers die.

As stated above, each language tree is composed of several subcategories, or *branches* of languages that share certain common characteristics. Languages in the same branch may or may not share commonalities of grammar and syntax, vocabulary and phonology. Some may use the same scripts and alphabets, while others show no similarity in this regard. For example, French and English have comparable alphabets, although French has diacritical marks not used in English. Russian uses a Cyrillic alphabet that has little resemblance to the variation of the Roman alphabet used for Polish. There are, however, words that sound quite similar in Russian and Polish, such as the word for *opportunity* (in Polish, *okazja [oh kahzh'yah];* in Russian, transliterated from Russian Cyrillic to English, *okaziya [oh kah zy'yah]*). Russian is an East Slavic language in the Indo-European family tree; Polish is a West Slavic language.

Some languages have an exact one-to-one correspondence between each letter of their alphabets and each sound in words; others have several sounds that are associated with the same letter or combination of letters. For example, in English /g/ can be "hard" or "soft" as in the words, *gorilla* and *cage.*

Languages vary in the number of consonants and vowels and how they are produced. There are tonal languages such as Chinese where words are pronounced with obligatory changes in pitch, or tones, to each stressed syllable. In Mandarin Chinese, the national language, a syllable might look like this example from Lyovin:

(C)(G)V (N or G) + Tone

where C represents a consonant, G a glide (nonsyllabic vowel), V a full vowel, and N a nasal consonant. There are 235 living languages in the Republic of China. Chinese is in the Sino-Tibetan language family; the languages of Myanmar and Thailand are also members of this family.

One of the oldest language families in Africa is the Khoisan. There are estimates that languages in this family existed some 60,000 years ago, which might place them beyond the commonly proposed time for the appearance of speech at 40,000 years ago. Khoisan languages are recognized by the incorporation of clicks in speaking; the grammars of the 22 languages are rather distinct. Most speakers are found in southwestern Africa around the Kalahari Desert regions, particularly in Botswana and Namibia. Some language scientists, such as Abram de Swaan, are concerned that the neglected study of such small language families as Khoisan might mean the eventual loss of information about the origins of language and the development of cultures prior to colonization by the Western world.

Laplace, Marquis Pierre-Simon de (1749–1827)

Marquis Pierre-Simon de Laplace, French mathematician and cosmologist, sought to explain the origin of the universe in terms of mathematics, physics, and philosophy. Although his conceptual reference for the temporal framework of the universe is not evident, other than under the general heading of orbital computations, Laplace's speculation within the nebular hypothesis poses a unique and interesting account for the origin of our solar system. Laplace was well known for his publications, *Systems of the World* (1796) and *Celestial Mechanics* (1825).

The existence of the solar system, with all the stars, planets, and comets, retains the appearance of regularity and stability. Laplace, with observations and mathematical computations, understood the governing factors and influence of both gravitation and motion among celestial objects. The vastness of our solar system, as evident by cometary orbits, was suggested as going beyond the then-known limits of our system. It was postulated that the solar system was a product of the expansion and contraction of a superheated sun whose atmosphere existed beyond the known planets. These newly formed planets possess similarities in directional rotation (including satellites), plane, and projection. Such commonalities were evidence of a common origin, albeit only a probable origin.

As for temporal facets of the known solar system, Laplace's concepts of time are held within the mechanical operations of a solar system in particular and the universe in general. The totality of time or age of the solar system or universe became secondary to operational understanding. Perhaps in Laplace's view, time measured within human consciousness becomes irrelevant when compared with the vastness and mechanistic system of the universe. Essentially, the birth of our solar system, like that of the universe, is indifferent to humankind's existence or to life in general.

It is rather interesting to note that before modern science and evolutionary theory, Laplace had mentioned, though briefly, that life may exist on other planets, or in his words, this is extremely probable. This assumption concerning the probability of the existence of life on other planets can be seen as a logical outcrop of the commonalities that are shared among the planets. This novel idea of extraterrestrial life is devoid of both human and divine interaction. Should life forms exist elsewhere in the universe, their existence becomes as irrelevant to our species as the universe is to human existence. The mechanistic nature of the universe, both in implementation and adjustments, becomes a set of interconnected subsystems in which individual life, assuming the existence of life on other planets, becomes insulated. Within Laplace's cosmology, there is no need for a divine essence that permeates the universe. Probability and mechanics replace the deity or force in both planetary and human existence.

In Laplace's substantial contributions, inferences regarding time become subtle statements without regard for theology and philosophy. The replacement of the Son with the Sun, as it were, has remarkable connotations for human existence and placement within nature. Laplace advised extreme caution to readers regarding his conjectures. Nevertheless, the materialistic explanation and justification seems to support this view. It is unknown if he held any theistic views before his death in 1827. However, the contradiction between science and traditional religious beliefs would surely become problematic. The concept of time as supported by science would be greater than human experience would allow. Timelessness or eternity would only be inferred as applying to the planets and the mechanical operations of solar systems and the universe.

Lascaux Cave

Lascaux Cave, like many archaeological sites, was discovered by chance. Four young boys stumbled across the cave in 1940 in southern France near the town of Montignac. Inside, these adventurers encountered what later researchers further explored and analyzed: a cavern filled with paintings and engravings on limestone walls depicting an array of images, which were determined to have been created millennia before. Today, Lascaux Cave's contents provide a glimpse of a people and a time in prehistory of which little else is known.

Lascaux is a multichambered cave extending approximately 250 meters in total length when considering all its areas. Chamber widths vary considerably so that the height of Lascaux's ceiling is equally diverse in size, going from less than one meter to several meters high, with variations in dimensions sometimes happening within a single chamber. As for when the cave was occupied, researchers conducted the dating of Lascaux's occupations through the use of multiple techniques including carbon-14 dating and the observance of animal species depicted in the wall art. The results of these tests have generated a range of corresponding dates, particularly between 18,000 and 16,000 years ago.

The actual paintings and engravings within the Lascaux Cave include a myriad of designs ranging from realistic and abstract images of animals to images and designs whose meaning remains undetermined. The images include horses, aurochs, bison, and felines. In addition to the wall art discovered in the Lascaux Cave, researchers discovered tools such as projectile points, miscellaneous flint tools used for engraving, and pottery sherds. As with other caves discovered in Europe with similar artwork, the paintings and engravings within the Lascaux Cave demonstrate the use of multiple techniques to generate images on stone. The materials used to generate colors for the wall art at Lascaux were predominately iron and manganese oxides.

Questions remain as to the importance and function of these images to their creators. Some researchers have postulated that the images were to serve as magical aids in hunting, perhaps in rituals; others have argued that the images were created as a form of decorative art. While answers to these questions remain elusive, interest in the images of Lascaux Cave remains strong. However, further investigation of the cave and its contents has been suspended and access has been restricted. This was considered necessary to protect the cave and its contents from continued deterioration caused by multiple contaminants that were destroying Lascaux's art. When and if access will be granted to researchers in the future remains to be seen. Fortunately, researchers have at least acquired a glimpse into the lives and activities of those who occupied and decorated Lascaux Cave, thereby providing us with some understanding of an era that remains relatively unknown.

Last Judgment

The Last Judgment refers to an event that, according to religious tradition, will occur after the world has ended and God pronounces his final verdict on the human race. For Christians, the Last Judgment is the stage in which all people are judged according to their behavior when they were still alive. The righteous will receive their reward and will spend an eternity in fellowship with God; however, the evil will spend an eternity in hell, acknowledging they had the opportunity for heaven but chose otherwise.

Some Christians believe that there will be only one judgment, because one's soul is asleep or unconscious between its demise and the Last Judgment (a view held by the religious reformer Martin Luther and others). Most Christians believe, however, that souls are not asleep and that they receive their punishment or reward after death. This first judgment is called the *particular judgment,* and it is different from the Last Judgment, where individuals are sentenced for their belief or lack thereof. This acceptance regarding one's final judgment is considered dogma by Roman Catholic believers, but the Church feels that the Last Judgment is not an actual trial, because the individuals already deceased are either residing in heaven or hell or working off their sins in purgatory—all resulting from their particular judgment at the moment of their death. Protestant believers in millennialism regard the two judgments as describing separate events, one at the moment of death and one after the end of the world.

According to this belief, the Last Judgment will take place after the deceased have been resurrected and undergone a complete reunion of the body and soul, where their evil acts are judged and their eternal sentence will be known to all before their fate before the resurrection is continued. At that specific moment, the joys of heaven and the sorrows of hell will be evident, because everyone present will be able to feel both pleasure and pain. This scenario appears most directly in "the sheep and the goats" section in the Book of Matthew. This belief regarding the afterlife can also be found in the books of Daniel, Isaiah, and Revelation.

Christianity is not the only religion that deals with the end-times. In Islam, there is *Yawm al-Qīyāmah* (the day of the resurrection). At a time preordained by Allah but unknown to humanity (at a time when people least expect it), Allah will consent for the Qiyâmah to commence. The archangel Israfel, named "the caller" in the Qur'an, will puff mightily into his horn, and out will come a "blast of truth." This specific occasion can also be seen in Jewish eschatology, where it is called "the day of the blowing of the shofar," found in Ezekiel 33:6. The Qur'an states that the Qiyâmah will last 50,000 years. Some Islamic scholars believe that this period refers to the vastness of man's spiritual advancement (one day is equal to 50,000 years), or that the day may signify the final triumph of Truth in the world, from the time when revelation was first granted to man.

In the Qiyâmah as envisioned, *Alameen* (humanity, the jinn, and all other living beings) are gathered upon a vast, white plain under a blistering sun. Each is completely unclothed, uncircumcised, and standing so close together that some are submerged in their own sweat. The depth of one's submergence in sweat depends upon how good or pious one was. Those that practiced good *adab* (following good etiquette) by following the Five Pillars of Islam daily are considered *nadirah* (shining and radiant). However, the expressions of the disbelievers are called *basirah* (miserable and grimacing). Although they are all nude, anxiety and fear are so great that no one thinks to look at another's nakedness. The creatures wait to be brought before Allah for their judgment, but they are terrified. The prophets plea to Allah with the phrase "sallim, sallim," translated as, "Spare your followers, Oh God." Those that followed Muhammad while he was alive, but then left

Islam after his demise, are apostates and are engulfed in fire. The angels are afraid, as state several *hadiths* (actions and utterances the prophet made while on earth), because Allah is livid with anger, more so than before or after.

In the Hindu religion, *pralay* is the specific time when the earth will be completely annihilated. Garuda Purana is one of the *puranas* (means "belonging to ancient time" and is a genre in Sanskrit literature) that are part of the Hindu body of texts known as the *smriti*. This sacred text discusses in vivid detail precisely what to expect after someone dies, specifying the different torments one can expect for the evil committed while alive, including being scorched in hot, boiling oil and given to bloodsuckers as prey. Some Western theologians see this scenario as being comparable to the Christian idea of Judgment Day.

Garuda Purana are directions given by Lord Maha Vishnu to Sri Garuda (also known as the king of birds—a *vahana* of Lord Vishnu). This specific purana looks at a wide range of subjects, including cosmology, various remedies for sickness, language syntax, and information regarding jewelry. The Garuda Purana is deemed the most respected Vedic book discussing the Nine Pearls (the nine sacred gemstones), and the second half of the tome deals with life after death. The Hindus residing in northern India customarily read this purana as they cremate the bodies of their loved ones.

Latitude

For the purpose of finding an relative location on the earth's surface with precision, geographers have drawn certain circles to which the position of any point may be referred. The art of navigation may have begun approximately 6,000 to 8,000 years ago; eventually it became a science of vast importance, particularly during Europe's age of discovery, when knowing one's exact position at sea saved both ships and the lives of sailors. With longitude being determined by time, and latitude by the angle of the sun at noon, mariners were able to find their exact position.

The earth, not a perfect orb, is an oblate spheroid, as discovered by A. R. Clarke in 1866. It is known that the earth rotates on its polar axis, or a line between the north and south poles. From this axis great circles can be contrived, such as the equator or 0° latitude, which has a 90° angle to the axis, and divides the earth in half, making the equator the largest or great circle. With the equator at 0°, the north and south poles are at 90° north and south latitude, respectively, with various angles from the axis in between. Latitude, then, is a line or parallel on the earth's surface that runs east and west at various angles from the axis and measures distance north and south on the earth's surface. Thus, the only latitude being a great circle is the equator with all other latitudes being smaller circles.

But, a number of great circles can be drawn on the earth depending on the angle from the axis, such as longitude. Longitude is a line or meridian that runs north and south but measures distance east and west (see the entry on John Harrison in this encyclopedia). Using an accurate timepiece such as a ship's chronometer, longitude can be calculated, and using a sextant the latitude can be found so that an exact position on the earth's surface can be plotted. Depending upon the accuracy required, latitude and longitude are measured by degrees, minutes, and seconds of an angle. The distance between lines of longitude decreases as one proceeds from the equator to the poles or as latitude increases.

It was Pythagoras, around 529 BCE, who first advanced the concept of the earth being a sphere with a moon evolving around the sun along with five known planets at that time. Later, Eratosthenes, around 300 BCE, was the first to place parallels on a sphere, but he named them after places. He also calculated the earth's circumference very accurately for that time, using the distance between two latitudes in Egypt. It was Ptolemy who first wrote about latitude and longitude in his *Geographia,* about the time that Alexander the Great was expanding Greek civilization.

The tools of navigation are a chart, a chronometer, a compass, and a sextant. Probably the first tool was the chart. The first charts, perhaps appearing as early as 2,700 BCE, were quite inaccurate. But, as time passed and technology improved, charts have become very accurate, so that contemporary charts actually a margin of error of less than one tenth of 1%. For measuring latitudinal position, the common quadrant was invented. From this crude instrument the astrolabe developed, first appearing about the 3rd century BCE. The astrolabe, like the common quadrant, was a device to measure the angle of the sun and various stars from the zenith. It was a cumbersome procedure involving several mariners. Later, the cross-staff was developed, with which the visible horizon was used rather than the zenith. Then, the back-staff or sea quadrant was invented by John Davis in 1590. Finally, in 1730, John Hadley perfected the sextant that is still in use today, commonly to measure latitude at noon using the angle between the horizon and the sun.

Another important tool is the compass. Crude though it may have been at first, it certainly decreased the chance of being lost at sea or in the desert. Perhaps the first compasses came into use about around the 11th century and were used by Norsemen. But, it wasn't until almost the 20th century that an acceptable compass was developed by Lord Kelvin for the British Admiralty. An accurate timepiece for use at sea, the chronometer, was developed by John Harrison in the 18th century for measuring longitude; this was the last tool to be developed for accurate navigation at sea. Today, the global positioning system (GPS) is used to find accurate location or position.

Latitudes of significance, besides the equator and the poles, include the Arctic and Antarctic Circles at 67.5° north latitude and 67.5° south latitude, respectively, and the Tropic of Cancer and the Tropic of Capricorn at 23.5° north latitude and 23.5° south latitude, respectively. These smaller circles represent the relationship of the sun's illumination at the summer and winter solstices. During the vernal equinox and the autumnal equinox, the sun's rays are directly on the equator, but during the solstices the sun's direct rays are over the tropics of Cancer and Capricorn, while the poles are in either total darkness or sunshine. These relationships between the earth and the sun are directly related to our weather patterns, seasons, and climate.

LAW

Law is a cultural achievement of humankind. It is subject to an evolutionary process in which a sense of right and wrong is developed, and the legal system as the end of this evolution is connected and continuously adapted to the conditions of human existence within a complex framework of social interaction. Essentially the main function of law consists in judging and sanctioning human behavior according to the judicial code of legal/illegal. It is possible to differentiate systems of law from an historical point of view depending on whether this function is intended to uphold and continue past customs or to steer the future.

Ancient and medieval systems of law are structurally characterized by a strong connection between law, politics, and morals; a case in point is the historical trial against Socrates (469–399 BCE). The law of those eras is deeply rooted in social customs and traditions. It is not so much the will of the lawmaker that determines what is right. What is right is primarily established by the authority of the judge, often personified by rulers themselves, who legitimize the law through their decisions. His point of view is principally directed toward the past as a time when conditions were right. And their verdict must uphold this continuity—old law is good law.

According to Georg Wilhelm Friedrich Hegel (1770–1831), legal thinking changed with the "invention" of subjectivity during the eras of the Renaissance and the Reformation. Individuals came to be seen as subjects who make themselves the persons they are. No longer did the demands of the past determine the life of an individual. Instead, individuals came to be defined by the tasks they choose themselves and their dedication to fulfilling them. But the joy of being the creative sculptor of one's own biography, the "plastes et factor," as Pico della Mirandola (1463–1494) fittingly calls it in his *Oratio de Dignitate Hominis,* is joined by worries about the future, a future that is essentially open and uncertain. Consequently, even today, the main task of law is to steer the future.

Temporality of Law

It has been obvious since the Enlightenment, or beginning of the Modern Era, that differentiations are made between law, politics, and morals. Living an upright life has increasingly become a question of outwardly obeying laws with no particular regard to moral considerations. The difference between making and enforcing laws has been institutionally reinforced. In general, the judge's verdict has been given a legal framework and thus become much less dependent on the center of political power—due in part to the condition that decisions must be made promptly. Law will always be power oriented, but, thanks to its own normative nature, it also establishes a bond with the future in that general expectations of an individual's behavior are stabilized—even though these expectations may be disappointed in individual cases. An essential factor that fosters this function of law is the construction of its own temporality.

Self-reflexivity is a prerequisite for this construction of law's inherent time: Law exists, because it is valid—specifically as long as it is valid. Differentiating between natural and legal time is therefore relevant for the validity of law. For example, as long as law is carried out under the auspices of a particular ruler, the validity of the regulations is bound to the "lifetime" of that ruler. As a result, the effectiveness of a legal system decisively depends on whether it is possible to create and change norms according to its own legal rules, in other words, to separate them from a specific time period. This process is particularly evident, because there is usually no mention made about when the validity of legal norms ends. They are, in a certain sense, "timeless." In some cases possible changes are even explicitly excluded, for instance by rhetorical expressions, such as human rights are "inalienable," human dignity is "inviolable," and the core of a constitution is valid "forever." These examples make it clear how the normative nature of law tries to immunize itself against social changes, especially in the field of politics. From a legal perspective, it may not be possible to prevent rulers from violating human rights; but by no means should they claim to act in accordance with the law when violations are committed.

Positivity of Law

The construction of a legal time provides for law's ability to structure its relationship to natural time: Legal validity means the present, which is differentiated from life's unchangeable past but also from the open (and, in that sense, more or less uncertain) future. In this corridor of the present, legal norms can develop their own "history" but are also latently subject to becoming history by a stroke of the legislator's pen as a result of their positive nature (i.e., by being recorded in a fixed, written form). Yet, seeing as their "time" is left to the will of the legislature, their history must be differentiated from the historical course of events. In effect, legal norms represent a particular moment in history that is highlighted in the course of time and conserved. Their changeability takes place in accordance with the given rules of law, in other words, in accordance with those norms that are higher and that determine the changeability of the individual legal norms. If that were not the case, norms could be changed at any time and would never develop a "timeless" effect.

The positivity of legal norms structurally guarantees a somewhat anachronistic character by welding past, present, and future under the conditions of law and creating a context that detaches itself from natural time. That is immediately obvious in the power of legal norms to call forth a specific future. They determine which behavior will be right and which will be wrong in the future. Of course, it is neither possible to know what the future will bring nor how individuals will behave, but it has already been established how their behavior will be judged legally. Following Immanuel Kant (1724–1804), this does not relieve individuals of their freedom to select their own goals and determine how they want to behave, but it requires everyone to respond to the law. Only with this common reference, which can be taken into consideration by evaluating the consequences of one's own behavior, is it possible to establish a common present.

Law also reacts in a similarly selective way in regard to the past; for all that remains, from a legal point of view, is what the legal norms specifically deal with. Everything else is nothing but the preface to a case that plays no role in determining the actual verdict. On the one hand, the past is permitted only in accordance with legal proceedings and admissible evidence. On the other hand, the unchangeable nature of the historical past does not touch the legal past, because legislation can changed retrospectively.

Legal Time

Legal time is expressed in a number of regulations. The calendar, for example, can be of individual nature in creating time divisions or in differentiating between standard time and daylight savings time. Typically, law leaves the measurement of time up to the laws of time, but it also connects it with value judgments about the quality of legal persons (e.g., being of legal age) or legal relationships (e.g., obtaining possession by prescription). Furthermore, appointments or deadlines are also objects of legal value judgments, for instance, when "immediacy" is mentioned, meaning that the person in question is required to act without culpable delay.

A perfect example of an individual construction of legal time measurement is the "legal second," a second that has no counterpart in natural time. It is purely an invention of law. Nevertheless, legal time is not completely unrelated to natural time, especially in regard to the omnipresent social problems of time. If law is to do justice to its function of binding and steering the future, it should always keep the conditional possibilities of legal behavior in mind: Things should be done on time. And that requires a worldly adaptation, a synchronization of law in connection with worldly situations, so that the rules can be followed within an appropriate period of time. Law itself should be "just in time."

Leap Years

The calendrical convention of the leap year is important to how we keep track of time. In the Gregorian calendar, adopted in 1582, a leap year is a year to which an extra day (February 29) is added. This extra day occurs in every year evenly divisible by 4. There is one exception to this rule.

For years marking the turn of a century (e.g., 2000, 2100), if the year can be divided evenly by 400, it is considered a leap year. The year 2000 was a leap year, whereas 2100 will not be.

Leap years correct for the difference between a solar year and our calendar year. A solar year is the time (approximately 365.25 days) it takes the earth to complete a single orbit around the sun. Counting 365 days from January 1 to December 31 means that in four Earth orbits around the sun, the calendar difference (4 times .25) would have the New Year starting on January 2.

Early in history, the Egyptians, with sophisticated astronomical skills, realized the calendar would get out of date with the solar year. They therefore began adding a day every 4th year. Later, the Romans used a calendar with alternating months of 30 and 29 days. This produced a calendar year of 354 days, which came up short by 11.25 days a year, meaning in just 3 years the calendar became out of synchronization by more than a month. Their imperfect solution was to add a month every 2 or 3 years, thereby causing more confusion.

The emperor Julius Caesar solved the problem in 45 BCE by establishing a calendar of 365 days and adding 1 day every 4 years. In order to bring the calendar into alignment with the solar year, he added extra months to 1 year. This worked for a while, but the remaining inaccuracy led to a difference between the calendar beginning of spring and the vernal equinox, which defines spring.

The first day of spring occurs when the sun is directly above the equator while moving from south to north. This day, when the lengths of day and night are equal, is the vernal equinox. Similarly, in fall, the autumnal equinox occurs when the sun is again directly overhead but moving from north to south. The slow changes in calendar year versus the solar year meant that by the 16th century CE, the beginning of spring had moved from March 23 to March 11. Pope Gregory XIII ordained the change the calendar in 1582 to move the 1st day of spring to March 21. To do this, 10 days were eliminated, so the day after October 4 was October 15. Non-Catholic countries changed as well but not until 1752 or later. Other cultures use leap years but with different methods to calculate when to insert days or even months.

Even with the new adjustments, there is still a very small difference in the length of a calendar day and a solar day. However, it will take about 8,000 years before the difference will amount to a full day.

adequate metaphysical system to answer the fundamental question, "Why is there something rather than nothing?" and examine the worldview resulting from his answer. After all, he observed, nothing is simpler and easier than something. But there *is* something, so why is that so? This entry discusses Leibniz's core ideas on metaphysics, including his concepts of space and time.

Two of Leibniz's guiding basic principles were the principle of contradiction (whatever implies a contradiction is false; thus, every true proposition is a tautology—always true) and the principle of sufficient reason (nothing exists without a sufficient reason why it is so and not otherwise). In an argument analogous to one of Saint Thomas Aquinas's five ways to prove the existence of God, he argued that the reason for the existence of the world cannot lie in the contingent things (they might have all gone out of existence at the same time, and then what?); it must lie in a necessary being—God. God is the metaphysically perfect substance, containing all perfections, such as omniscience and omnipotence. Leibniz's idea of God seems to be like a kind of supermathematician; God examined all the infinite number of possible worlds and chose the best, that one that is "simplest in hypotheses and richest in phenomena." In an effort similar to work done by Johannes Kepler in determining the optimum dimensions of a wine cask to contain the most liquid with the least material required, Leibniz's God might have applied a kind of minimax procedure to come up with the optimum combination of characteristics for the world. If there had been no best combination, there would not have been a sufficient reason for God to create a world, and there would be none; thus this must be the best possible world. When God *thought* the best possible world, his thoughts *became* the world. (Leibniz argued that thoughts require signs, and the world is the sign of God's thoughts.)

René Descartes (1596–1650) had thought that the essence of (physical) substance was extension (as contrasted with mental substance, whose essence was thinking), and so a geometrical account could explain all properties of bodies. Leibniz saw that this was inadequate, that a geometrical account of motion failed to take inertia and momentum into account. Thus Leibniz concluded that the essence of substance is *action,* it has a force (*conatus*), a striving to change (for the better). The basic building block of the world, thought Leibniz, must be indivisible, a formal atom—a *monad.* Leibniz's monads are like little minds; it is as if bodies are a byproduct of these minds (he sometimes refers to a body as a momentary mind). These monads are "windowless," unaffected by anything other than their own programs. It is as if each monad is driven by its own program (something like a computer program), its internal tendency to move from one state to the next. This "program" has existed as long as the monad and determines its current state and what state it will be in next. It is like a finite-state automaton, with its initial state and the function that describes how it changes; these totally define it. Its principle of change Leibniz calls "appetition"—it is a striving for perfection. The world itself cannot *be* perfect, for then it would be God, and there could not be two Gods (there is not a sufficient reason for *any* two identical things, according to Leibniz); but the world strives toward perfection, and it is this striving that underlies change. Each monad, since its program totally defines it, contains its future and the traces of its past: "The present is big with the future, the future might be read in the past, the distant is expressed in the near."

Each monad has perceptions, which are its perspective on the universe, and Leibniz says that each monad reflects the whole (universe), though imperfectly. Thus it may contain the whole, but not be aware of all its aspects, or some of them may be less "in focus" than the nearer ones. A monad's perceptions are its properties; thus the monads form a plenum, because otherwise a monad could perceive nothingness, but nothingness cannot be one of its properties. A monad is a "concentration and a living mirror of the whole universe, according to its point of view." Thus monads make up the world and perceive the world at the same time; they are all part of the world harmony created by God's thought. Thus there is hope for knowledge of the truth regarding objective reality (of that world). The dominant monad of the aggregation of monads that gives rise to a body is its *soul* monad, which is dominant over the others. It has memory and reason and is farther up the hierarchy of monads. A rational soul, in discovering truth through science (or mathematics or logic), imitates what God does in the world as a whole; it is a kind of image of God. It tries to know God, but since God is infinite, it can never achieve full knowledge, but it can continue striving in "perpetual progress" (and never get bored!).

Leibniz argues that there are two realms: the realm of Nature and the realm of Grace. Because perceptions (and feelings) cannot be explained by mechanical causes (like trying to find your perception/idea of red by surgically examining your brain), there must be another realm (of final causes) that governs the soul monads (in their striving toward the best, to maximize good over evil). In the realm of nature, bodies follow the laws of efficient causes; these two realms will, according to Leibniz, always be in harmony, as God thought them. There will be two possible explanations, one following final causes, the other following efficient causes in the realm of nature, for every event; Leibniz says they are "equally good" explanations. Thus the mental and the physical realms are in sync because of God's preestablished harmony; they are like two clocks created and started off by the same watchmaker that continue to tell the same time even though there is never any interaction between them, or like members of a chorus who sing the same music even though they never touch each other or directly interact. They run in perfect parallel (which is his explanation to Descartes' problem of how mind and body affect each other, without Descartes' desperate solution that they interact in the pineal gland).

Leibniz views space and time as relative (see the entry on Newton and Leibniz). Space is created by the positioning of bodies, bodies are not placed in an absolute preexisting container space, and time is the succession of states (physical or mental) of bodies or minds. Without bodies, there is no space; without change, no time. Space and time are thus, for Leibniz, relations; they are ideal (based in ideas), phenomenal. Time is the more fundamental, because monads have their internal programs to move from one state (condition) to another, in their striving toward perfection. The difference between one state and another state creates their temporal relation (first one state, then the next, creates the temporal relation of earlier and later time, of past and present, or present and future). This would be time in the realm of grace, from one perceived state to another. Monads that congregate together as a body guided by a soul monad act and change in the realm of nature, so time in that realm would measure the difference between different bodily states. Derivatively, physical space would be defined by the relative position of bodily monadic aggregates.

Lemaître, Georges Édouard (1894–1966)

Georges Édouard Lemaître, a Belgian engineer, astrophysicist, and Catholic priest, was known for his theoretical contributions to the understanding of the origin of the universe. Theologically unorthodox and based on available scientific evidence, Lemaître's theories postulated that the universe was expanding from an unknown point of origin. This expansion, as evidence suggested, would entail that the origin of the universe would require vast differences in space and time from the condition of the universe today. In what is now commonly referred to as the big bang theory, Lemaître speculated that the universe was a product in the breakdown of the primeval atom, whereby the stars, planets, and nebula exist in an expanding universe. Furthermore, he attempted to bridge the gap between science and religion by suggesting that there are two distinct metaphysics, one for science and another for religion. Lemaître was known for his publications *Discussion on the Evolution of the Universe* (1933) and *Hypothesis of the Primeval Atom* (1946).

Contrary to previous concepts of the universe as being both infinite and static, scientific contributions from Edwin Hubble (1889–1953) and Albert Einstein (1879–1955) suggested that the universe was not static but expanding and relative. This would have serious consequences for both the traditional concepts of time and space. Although Lemaître held that the mass within the universe is constant and distributed in a nonuniform manner, the expansion of the universe would indicate that the velocity of expansion will change in time and space. Insofar as the origin of the universe, Lemaître suggested, was based on quantum theory, the quanta would decrease in number and increase in the amount of energy. When reduced to a few quanta or a single quantum whose atomic weight would reflect the total mass of the universe, the concepts of both time and space would be devoid of meaning. This primeval atom would contain the undetermined nature of the present universe; whereas spatiotemporal reality did not begin until the disintegration of this primeval atom.

Lemaître's theory, though speculative, had a profound impact on traditional cosmology. Philosophically and theologically, the beginning of the universe would call into question previous human ontology and teleology. The existence of God, the concept of the void, the stability of the universe, and humankind's place in nature would conflict with traditional perspectives. Lemaître, a proponent of dissonance, never acknowledged this conflict between science and religion, for he held that science and religion were two separate and different types of knowledge. However, an exact epistemological synthesis—understanding and blending the temporal nature depicted by science and what is stated in scripture—was never stated, and thus the two accounts remain irreconcilable.

Although problematic, Lemaître's contribution to science and cosmology remains as important as it is controversial. According to Lemaître, the universe, like the planets, had a definite beginning. Time and space, in relation to the newly "created" universe, would provide the unwritten basis for the development of preexisting matter in the universe. Humankind, a minute part in this cosmological unfolding of time and space, would not only ponder the evolution of our species but also the evolution of the universe.

LENIN, VLADIMIR ILICH (1870–1924)

The Russian revolutionary Vladimir Ilich Ulyanov, who later adopted the name V. I. Lenin, was born to Mariya Blank, a doctor's daughter, on April 10, 1870, in Simbirsk, where his father was an educator, schoolmaster, and inspector of primary schools. He was one of six siblings.

The second child and oldest son, Alexander (Sasha), went to St. Petersburg University in the fall of 1882, where he majored in natural science. While there, he joined an organization known as Narodnaya Volya, or the People's Will. This terrorist wing believed in a socialist party led by the working class. Socialism was the logical extension of democracy, but czarists did not allow for peaceful development of democracy. Legal opposition was not allowed. The only option for purging the official hatred of any popular movement toward socialist democracy was terrorism. In February 1887, the People's Will planned the assassination of Alexander II, czar of Russia. The police discovered the plot, and as a result, Alexander Ulyanov was executed in 1887 for being a part of the group that attempted to kill Alexander II.

Because of this experience, young Vladimir was propelled into revolutionary activity. As such, Vladimir would become a leader in the Russian Revolution. A diligent scholar, Lenin attained a mastery of social theory and a sound understanding of the history of social movements and historical trends. As a leading activist, Lenin wrote a series of articles that would not only serve as a guide for revolution in Russia but also lay the intellectual foundation for what would become Marxism-Leninism. These articles included *The Development of Capitalism in Russia.* In this work, Lenin tried to prove that that by 1900, Russia had already been incorporated into the world capitalist system. As a result, the peasants were rapidly being divided into capitalist farmers and the rural proletariat. Russian industry was divided between traditional handicrafts, backward manufacturing, and a modern machine industry in which a great deal of foreign capital was invested.

In 1902, Lenin wrote the pamphlet, *What Is to Be Done?* "Without revolutionary theory there can be no revolutionary movement," Lenin stated. He wrote that unions by themselves would only lead to struggles over wages and working conditions; a socialist consciousness needed to be introduced from outside the working class. This would require an organization of professional revolutionaries. The organization would need to be disciplined, conspiratorial, and centralized. The "party of a new type" would become the vanguard of the working class and would lead, but remain separate from, the broader democratic workers' movement.

In 1904, Lenin wrote *One Step Forward, Two Steps Back*. At this time, Lenin's writing was based upon the assumption that the workers' party needed to be taken over by those workers who were educated with a socialist awareness. The intellectuals were undependable, obsessed with eccentricity, anarchism, and egoism, and had an intense horror of discipline.

Materialism and Empiriocriticism was written in 1908 as a rebuttal to the physicist Ernst Mach, who had stated that reality was only the actuality of our experience, and therefore science could record only our subjective experiences. In *Materialism and Empiriocriticism,* Lenin affirmed that science is the observation of the material universe, existing independently of the observer. Physical sensations are the direct connection to the external world. Every ideology is conditioned by its historical setting. Science is no different, yet science is valid. It is independent of the observer to the degree it corresponds externally to tangible nature.

Sensations, wrote Lenin, are our obvious link between our consciousness and the external world. Energy affects our bodies, which are excited by stimuli and provoked by the external world. This in turn excites a chemical response in our nervous system and is transformed into consciousness by the mental activity of our brains. The energy of the exterior excitation changes physical and chemical corporeal activities and is transformed into sensations. Sensations are changed into consciousness. Consciousness is cast and grows. Consciousness interprets sensations. This implies a dynamic and interactive process in mental development. We learn through actively interacting with both the social and physical environment.

Physical and social realities, Lenin noted, are constantly changing. There is an eternal process of conflict and fusion of conflicting parts leading to the death of the old and the birth of the new. This simple logic is basic to anything that can be studied. It is more than a part of mental processes, or the way that the world is studied and understood. This logic is broadly similar to the way the universe is constantly evolving. The opposition and combination of components forming ever-greater wholes is an approximation of what is really happening to the universe outside the mind. When these opposing and interacting parts are fused, there is something basically different being formed that will replace what went before. The new thing soon develops its own tensions as it begins to break down. These new tensions not only lead to the extinction of this entity but also give birth to its replacement.

Science, according to Lenin, is a specialized form of logical practice, founded upon the certainty that there is an external reality that is independent of our consciousness. Through careful observation and the use of specific scientific method to analyze observations, this external reality is more closely revealed than by any other technique of understanding. Because all scientific observations are approximations, science is a constantly growing discipline. Every generation will get progressively closer to this external reality. The limitations of the categories used are always qualified, modest, changeable, provisional, and approximate. Each scientific breakthrough is built on earlier breakthroughs. Because every ideology is historically conditioned, science itself occurs in a specific historical setting. This is the basis of materialism; the fact that political states are a reality can be understood in terms of matter in motion.

In 1908, Lenin wrote *The Agrarian Program of Social Democracy in the First Revolution.* Most peasants in Russia were downgraded to farm workers and tenant farmers. Only a small number of peasants had enough land to endure as farmers. A minority of the farmers were rapidly becoming more like American capitalist farmers. The large feudal *latifundium* (large estates) remained. The *latifundiums* slowly developed into large farms modeled on the German Junker type. With the breaking down of feudalism, capitalism developed. The market economy merely meant that the state was becoming a major landowner.

Lenin contributed to the Marxist theory of imperialism with his text called *Imperialism: The Highest Stage of Capitalism.* According to Lenin, imperialism was "the final stage of capitalism," a sign of the breakdown of capitalism and the transition to socialism. Competitive capitalism of the early 19th century had become increasingly centralized, with fewer competitive firms surviving the increasingly intense competition. As a result, capital became concentrated in larger firms. In this way, "monopoly capitalism" was able to create ever-larger surpluses by limiting competition. Markets at home became glutted, and investment opportunities in the industrialized nations declined. This meant that corporate capitalists were forced to export capital to ensure future profits. This became, for Lenin, a major distinction between the earlier competitive capitalism and its later descendent, monopoly capitalism. Competitive capitalism exported finished goods in exchange for raw materials produced in the poor areas of the world. Monopoly capitalism exported its capital to these areas. Capital was invested to create modern ways of extracting those same raw materials. Instead of mines being owned by the local traditional elite, capitalists in the rich industrial nations owned them. This caused an increase in overall capital on a world scale while arresting development in the main capitalist countries.

The principal feature of modern capitalism was the domination of monopolist consolidations by giant capitalist firms. The monopoly control was most firmly established when all sources of raw materials were jointly controlled by several large surviving firms. Monopoly capitalism, with a few highly centralized firms effectively dominating the economy, created imperialism out of its own needs. In order to find continued profits in an already overdeveloped economy at home, investments flowed to less developed areas of the world, where the capitalist economy had not reached a saturation point, therefore making profits much higher. Export of capital was the fundamental principle of imperialism. The export of capital greatly influenced and hastened the growth of capitalism in those countries to which it was exported.

The next two most important of Lenin's works, which outlined his sense of history, were *State and Revolution* and *"Left-Wing" Communism: An Infantile Disorder.* Both were models for the direction revolution would take. In *State and Revolution,* Lenin maintained that the workers could not merely take over control of the existing state; they needed to smash it. Then, when the returning bourgeoisie was overthrown, the state would wither away. In *"Left-Wing" Communism: An Infantile Disorder,* Lenin disapproved of leftists in the West for disregarding parliamentary tactics and legal opportunities to create their own socialist revolution. Lenin also summarized the significance of all communist parties that had become centralized and disciplined and were following the lead of the Russian party.

Libraries

A library is a repository for recorded information. The concept of a library has evolved but has existed in some form for thousands of years. The ability to record information in a format more permanent than oral tradition added another dimension to human communication time. Information that has been transcribed into a solid, visual format can be accurately remembered over generations. While libraries have physically changed over the course of history, their cultural role has not. Libraries and librarians are responsible for acquiring, maintaining, and providing access to information. They keep business, legal, historical, and literary records of a civilization. Libraries could be considered the memory of a society.

The word *library* is derived from the Latin *liber,* meaning "book." Traditionally, library refers to a collection of books, or a room in which such a collection is kept. In the earliest days of recorded information, however, there was no distinction made between a record room (archive) and a library, so it could be said that the concept of a library has existed for as long as writing.

The Ancient World

The emergence of large, complex civilizations in Egypt and Mesopotamia 6,000 years ago necessitated the development of writing to provide the record keeping needed to maintain a stable and orderly society. Ancient civilizations in East Asia indicate similar development, with collections of official records dating to as early as the 12th century BCE in China.

Hieroglyphs emerged from the artistic history of Egypt, starting a tradition of literacy and recorded knowledge. This writing system used pictures to reflect words and ideas. As writing became more widespread and vital in Egyptian society, simplified glyphs were developed, resulting in hieratic (priestly) and demotic (common) scripts. These cursive writing forms were better suited to writing texts on papyrus, greatly increasing the speed in which scribes could write business or literary texts.

In Mesopotamia, the most abundant material for information storage was clay. Cuneiform writing, done with a wedge-shaped tool, was impressed into tablets of damp clay. After the tablets dried, they were permanent. A temple dating to the 3rd millennium BCE in Nippur had several rooms filled with tablets, indicating the existence of a well-developed archive. Large collections of tablets also appear to have been deliberately organized with a catalog listing the contents of the collection.

In East Asia, records were first inscribed on bone, stone, bronze, or tortoise shell and date to the Shang dynasty (approximately 1200 BCE). By the 8th century BCE, less durable materials such as bamboo or wooden slats were used. Lengths of silk appear in the historical record during the 4th century BCE. Paper was invented in China in the 1st century CE, but it would take several centuries for it to completely replace the cumbersome bamboo or the expensive silk. In China, records were often destroyed during war or purged when new rulers assumed the throne, so history would appear to begin during their reigns. The Han dynasty, which succeeded in 206 BCE, ended the repression. They recovered earlier works that were hidden, encouraged writing and record keeping, and developed formal methods to classify information.

In the Western world, libraries had their origins in classical Greece and Rome. Most of the larger Greek temples appear to have had libraries and record rooms. As early as the 6th century BCE, Greek leaders were constructing large public libraries, and a sophisticated book trade existed in Athens by the 5th century BCE. Many large book collections were owned by wealthy citizens. One of the finest private collections of ancient times was owned by Aristotle. His collection was seized and taken to Rome by Sulla in 86 BCE as war booty. From there, copies of his texts became the basis of the greatest library in antiquity at Alexandria.

The Alexandrian library was planned by Ptolemy I in the 3rd century BCE and established by his son Ptolemy II. The founders of this library intended to collect the finest copies available of every piece of Greek literature and arrange it systematically to facilitate research. It was staffed by many famous Greek writers and scholars and was estimated to contain 700,000 scrolls of parchment and the first use of vellum.

Private libraries were common in classical Rome. It was considered fashionable to have a library in your home. Interestingly, imperial Rome is known for military skill, not intellectual life, but Romans revered books and transported hundreds of collections virtually intact back to Rome when plundering foreign lands. Most of the captured libraries were incorporated into the private libraries in officers' homes. Eventually, Romans decided that placing these collections in large public buildings would display the glory of Rome. Julius Caesar is credited with actually planning the first public library facility, but he died before the plans could be completed. Tiberius, Vespasian, Trajan, and many later emperors created libraries throughout the city.

The Middle Ages

Books were thought to be essential to spiritual life. As monastic communities were established in the 2nd century, monasteries included a library for reading and study. They also incorporated a *scriptorium,* a room where manuscripts were copied. Strict rules existed for the use of the books, but at the same time, monasteries often lent materials to other monasteries or to the public. The contents of these libraries included scriptures, religious histories, philosophical writings, and some secular literature. Unknown scribes copied texts repeatedly for generations, preserving cultural transmission through the Middle Ages. Important developments during this time include the codex, or book, and the use of vellum (animal skin) for the pages of books. This new format for recording information was far more durable than papyrus. After universities were founded in the 11th century, students who were also monks returned to their monasteries and deposited their lecture notes in the monastery collection, expanding its contents. The libraries of newly founded universities and monasteries were the main places to study until late in the Middle Ages. Books were very expensive, and only the wealthiest individuals could purchase copies.

The Renaissance

Private book collections developed again through the 13th to 15th centuries. The growth of commerce, widespread education and literacy, the new learning of the Renaissance, and the invention of the printing press by Johannes Gutenberg widened the circle of book collectors. Paper also became the preferred writing surface in the 15th century. Paper and the printing press made books far cheaper, faster, and easier to produce for the rapidly growing reading market. Along with a sophisticated book trade, many fine public libraries opened in Italy and throughout Europe.

17th and 18th Centuries

In the 17th and 18th centuries, book collecting everywhere continued to expand. In Europe and North America, many fine private collections were formed that eventually became the core of national and university collections. National libraries today receive one free copy of every book and periodical produced in that country and are maintained with national resources. They attempt to collect and preserve the nation's literature while keeping an international scope. A new form of library also developed at this time, the circulating library for popular literature. Circulating libraries were operated by booksellers for profit, but they made a large body of literature available to the general public for a nominal cost.

20th Century

The look and feel of libraries has changed drastically since the 19th century. A leading figure in transforming library service was Antonio Panizzi, an Italian refugee who began working for the British Museum in 1831 and was its principal librarian from 1856 to 1866. He revolutionized library administration and developed a code of rules for catalogers. He also recognized the potential of libraries being open to all for research and reflected this notion in his planning of the British Museum reading room. With the emergence of a large reading public and an enormously expanding stock of books and periodicals, libraries had to expand their organization and storage capacities.

The paradigm for libraries shifted again in the 20th century with the advent of new information technologies. An information explosion after World War II created a need for new methods to store information. Compact movable shelving, microfilming, and remote storage evolved to address this need. Today, the vast quantity of information available through databases and other online resources requires computers and highly qualified professional librarians to help the public navigate through the overwhelming amount of information freely available to everyone. Many types of libraries and services are available today. There are great national libraries, university and research libraries, and public libraries that are generally open to everyone. In addition, there are special libraries founded to meet the research needs of a specific group, school libraries for the students of that institution, and private libraries that reflect the interests of the collector. Archives exist as separate entities today and are generally collections of papers, documents, and photographs preserved for historical reasons.

The Future of Libraries

Libraries have always been driven by the needs of their users. That will not change. Today, most libraries open to the public are fairly neutral in their collections—they have something for everyone. This may have to change given the exponential growth of information available. To be able to manage diverse subjects and formats, while also preserving existing collections with limited funds, is becoming increasingly difficult. Libraries of the future will likely have to specialize and tailor their collections to specific groups of users. Resource sharing between libraries will continue to grow in importance.

While the appearance of libraries and the methods of doing research will continue to change, the main purpose for their existence is unchanging. Libraries and librarians will continue to be responsible for acquiring, maintaining, and providing access to the collective knowledge of a civilization, no matter what form that knowledge may take in the future.

Life, Origin of

The origin of life remains today one of the most challenging puzzles to science. The challenge is twofold: (1) qualify the essence of life and (2) explain its appearance on Earth. Although both aspects have been subject to much scientific investigation, no satisfactory explanation has been formulated so far.

Life is often defined as the distinctive property of particular physical systems: living organisms. One way of defining life is to say that a physical system is alive if and only if it can replicate with variation and therefore be submitted to natural evolution. From a temporal perspective, the origin of life can therefore be defined as the point in time when, for the first time on Earth, a particular physical system simultaneously displayed a set of given properties, namely replication and variation.

How life is defined has a strong impact on the question of its origin: Taking a more restrictive definition of life, one that would for instance require that such replicating systems with variation be able to complete at least one thermodynamic cycle, would move forward the point in time when the origin of life might be traced back to. In addition, defining life as a collective set of properties of living organisms also raises the question of the temporal order of appearance of each of these properties: For instance, which appeared first, replication or variation?

Roughly speaking, life most likely appeared on Earth some 3.8 billion years ago. This dating is framed, on the one hand, by the formation of the planet some 4.5 billion years ago, with still some heavy meteoritic bombardment until about 4 billion years ago; and, on the other, by the oldest cellular fossils dated 3.6 or potentially even 3.8 billion years ago. As such, the time frame available for life to appear is about 200 to 400 million years.

The first modern hypotheses of the origin of life were formulated in the 1920s by Alexander Oparin and John B. S. Haldane, separately: The first living systems would have appeared in a primitive ocean of organic molecules, all of them resulting from prebiotic chemical processes, that is, chemical processes compatible with the physicochemical conditions believed to be those of the primitive Earth, before the appearance of life. The first scientific experiments supporting these hypotheses are those of Stanley Miller in 1953, who demonstrated the possibility of synthesizing certain organic molecules—amino acids—under prebiotic conditions. Since then, the prebiotic synthesis and chemical behavior of numerous other organic molecules in prebiotic conditions have been investigated, including those of proteins, lipids, and nucleic acids. Today, the scientific field of research on the origin of life draws upon a large number of disciplines: molecular biology, biochemistry, prebiotic chemistry, and theoretical biology but also planetology, geology, or even astronomy, in order to define the environmental conditions of the primitive Earth or to search for primitive life forms on alternative planets.

Far from having occurred at a particular moment or point in time, as a sudden event, the origin of life is likely to have been the result of a long and gradual process. The question remains whether this gradual process is truly continuous or might otherwise display some sorts of sudden steps akin to phase transitions, for instance. In the latter case, such steps could be used as particular landmarks for defining the origin of life, even if these are still speculative today. Due to this specific time frame of several hundred million years during which life is thought to have appeared on Earth, experimental research on the origin of life has to consider a broader scope of physicochemical possibilities than usual, for instance chemical reactions with longer characteristic times than in usual laboratory experiments, or environmental conditions that would be much different from current ones (temperature, pressure, pH, etc.). Over such long periods, the role of chance also might come to play an important role, enabling unlikely molecular encounters to happen or precellular components to assemble and disassemble in many different ways as in a "tinkering" process. Therefore, life as we know it on Earth would somehow also keep the trace of numerous specific events or "frozen accidents," all of them highlighting the very historical nature of life.

Life as we know it on Earth might be one particular instance of a more generic phenomenon, the characterization of which is among the goals of artificial life research. What is more, not only could life appear under different forms, but it might also appear in different places in the universe. Exobiology research focuses in particular on the quest for extraterrestrial signs of life. Such a discovery would not only be an astounding discovery, but it would also shift the question of the origin of life and raise the question of its potential perennial existence over the known history of the universe, an old theory known as panspermia. In addition, life as we know it today might not be life as it has been in past, or, as a matter of fact, life as it will be in the future. Life as we know it today might not be life wherever nor forever.

Could there be, as well, multiple parallel pathways leading to the origin of life? If life is defined as a set of collective properties of particular physical systems, its origin might thereby be traced back to the chains of events that led to the appearance of each property separately and, as such, of those specific components enabling the physical systems to display such properties. Hence, for instance, the origin of life on Earth might be traced back to the origin of prebiotic proteins, prebiotic nucleic acids, or even prebiotic lipidic compounds, all of them being basic components of current living systems. In such a case, the origin of life could dissolve into as many origins as there are components necessary to build a living system.

Could life still be originating on Earth as we speak? This would make the origin of life a continuously recurring event, continuously generating new origins, so to speak. Such a hypothesis appears unlikely: It would require not only abiotic chemical processes, that is, chemical processes able to produce organic molecules without appealing to compounds of existing living organisms, but also physicochemical processes that could lead to the organization of these molecules into living systems. However, it appears extremely likely that most abiotically synthesized organic molecules today would end up being immediately assimilated by existing living organisms, without any possibility to further assemble themselves into new living systems, life thereby preventing any new origination of itself.

Life Cycle

All living organisms have a life cycle beginning with the initiation of life and continuing until death. Scientists generally consider a life cycle to encompass the changes that an organism experiences from the beginning of a specific developmental stage until inception of the initial developmental stage in the next generation. The stages an organism will experience and the length of the life cycle varies widely across species. Species survive only when sufficient offspring complete the life cycle to continue the species. Such cycles vary from minutes to multiple years.

The time to complete a life cycle is generally correlated to the size of the organism. Bacteria complete their life cycle in 30 minutes by dividing to form another generation. Higher organisms take much longer. The giant sequoia, for example, produces its first fertile seeds after 60 years. Some plants and animals die after reproducing, with reproduction symbolizing the end of the life cycle. Other animals, notably humans, live for many years after their reproductive cycle is complete.

Most simple organisms complete their life cycle in one generation with an initial splitting in two of an adult, the growth of the new organisms, and upon reaching maturity, the division of each one into two new individuals. Higher animals can also have a single generation with the fusion of male and female sex cells to create the embryo and the growth of the offspring to reproductive maturity when they produce sex cells that create new offspring. Plant life cycles, however, are usually multigenerational. A spore will germinate and grow into a gametophyte. At maturity, the gametophyte forms gametes. With fertilization, the gametes develop into sporophytes. Once reproductive maturity is reached, the sporophytes produce spores and a new life cycle begins. This process is frequently referred to as “alternation of generations” and occurs in some fungi and protists as well.

The time the young animals spend developing prior to being born (the gestation period) or hatched varies across species. Small marine animals frequently produce large numbers of tiny eggs that hatch at a very early developmental stage, while others produce fewer, larger eggs with the young exiting at a more advanced developmental stage. The smaller young will need longer to develop before becoming adults, while the more fully developed young move quickly into adulthood. This effect is common in higher organisms as well. Generally the more developed the young, the fewer produced in one reproductive cycle, as there is more chance of the young surviving. Larger animals take longer to bear their young, as the young must be ready for the hardships of life. Elephants have the longest pregnancy period of any mammal at 22 months. Smaller animals have shorter gestation periods. For example, the domestic cat has a pregnancy term of approximately 9 weeks.

Hibernation

Hibernation is a state of dormancy that some animals enter into during cold months of the year. Bears are well known for this; however many other animals hibernate, including rodents. Hibernation allows the animal to exist during times of food shortage and unfavorable conditions. In the spring, the animal rises and is generally ready to reproduce. Plants and seeds also experience dormant periods until conditions improve to allow them to continue their life cycle.

Metamorphosis

A number of animal species include metamorphism in their life cycle. Metamorphosis is a process of great change between stages in the cycle. The stages provide a way for the organisms to live separately from other stages in order not to compete for food or habitat. For example, frogs lay eggs in the water. The embryo quickly grows and hatches into a tadpole. The tadpole lives in the water and breathes through gills. As the tadpole grows, its tail shrivels, and legs and lungs develop. When the gills disappear, the tadpole comes to the surface and is now considered to be an adult frog. Most species of frogs grow into adults within one season and reach reproductive maturity within a year. Thus, mature frogs and tadpoles live in very different habitats, lessening the competition for food and enhancing other aspects of survival.

Butterflies also use metamorphosis in their life cycle. Each one moves quickly from a caterpillar (larval) stage to a pupal or chrysalis stage, when the larva is dormant, and then emerges from the pupa as a full adult ready to reproduce, with one cycle normally taking a year to complete. Fruit flies also undergo metamorphosis, changing from one form to another completely different form, moving from an egg to larva to pupa to adult. Each phase is a natural phase of the life cycle. The whole process normally takes about a week. Other animals that use metamorphosis are amphibians (toads, newts, etc.) and a wide variety of insects.

Invertebrate animals have a variety of life cycles. Metamorphosis, a series of rapid physical changes, is common. Most insects lay eggs. Incomplete metamorphosis, or simple development, involves the eggs hatching into nymphs and moving to the adult stage. Complete metamorphosis, or complex development, includes a pupal stage between the larval and adult stages. As immature larvae and nymphs grow, they shed their exoskeleton, which is a tough exterior skin. Each time the exoskeleton is shed, the new stage is called an *instar.* The final instar develops into a pupa in complex life cycles or into an adult in simple life cycles. Most common insects generally have three to six instar stages; thus a complete insect life cycle includes the egg, larval, three to six instar, and adult stages. Ladybugs provide a good example of complex development. The adults lay eggs that hatch into wormlike larvae, which go through several instar stages, and the final instar covers itself in a hard pupa and emerges as a new adult. The life cycle takes 4 to 7 weeks. Most insects have a 1 year life cycle. However, wide differences exist. For example, the life cycle of a fruit fly is 1 week, while one species of cicada has a life cycle of 17 years.

Reptiles

Most reptiles are egg laying (oviparous). There is great variety in reptile mothers. Some eggs are laid and left on their own, although usually in well-protected and hidden nests. Sea turtles lay their eggs on sandy beaches and return to the water, leaving the young to fend for themselves. Other species stay with the eggs and aggressively defend the nests. Examples of these include crocodiles and pythons. Some reptiles are ovoviviparous, including many species of snakes and lizards, with very thin shelled eggs remaining in the mother's body. These species appear to have live births, but in reality the eggs hatch just before the young are born, making it seem that the young are born rather than hatched.

Reptiles produce hatchlings that are exact replicas of the parents. The hatchlings must quickly grow and learn to defend themselves. Many reptiles grow through a process of molting, where the outer layer of their skin is shed to allow for physical growth. The molting times will vary. Most reptiles will molt shortly after hatching. During periods of rapid growth, molting can occur four or more times a year. Adults still molt but more infrequently, generally one or two times a year.

Fish

Fish are primarily egg laying. Many species lay the eggs and leave them alone to survive. Most eggs are soft shelled. Some species of sharks lay eggs with a tough outer coat to help protect the eggs. A few species protect the eggs through burying them in the sand or by being "mouth brooders," where one parent will hold the eggs in his or her mouth until they hatch. Male seahorses have a special pouch where they hold the eggs. Baby fish are called "fry." The young are generally able to reproduce within a year after birth.

Birds

Birds lay eggs on land even if, like ducks and loons, they spend more time on the water. Most birds stay with the nests (brood) to keep the eggs warm and safe from predators. Eggs vary in size, from the very small robin egg, approximately 1 inch around, to the large ostrich egg, which is 5 to 6 inches around. Hatching time is 12 to 14 days for robins and 35 to 45 days for ostriches. Ostriches will reproduce at 2 to 4 years of age, while robins reproduce within a year. Comparing the robin and the ostrich provides further evidence that the size of the organism affects the time taken for each stage of the life cycle.

Humans

Humans are generally considered to have four stages in their life cycle: infancy, childhood, adolescence, and adulthood. The gestation period is 9 months. Infancy is the stage between newborn and 2 years of age. Many changes occur in this stage, and the infant learns to walk and talk. Childhood occurs between 2 years of age and puberty (adolescence). Many physical changes occur in childhood, such as the rapid development of teeth and bones. The time of puberty varies but usually starts at 8 to 12 years of age. Adolescence is a period of many changes, including the sexual maturing of the human body. Males continue to grow physically until they are 21 years old, while females usually reach peak physical growth by 18 years of age. During adulthood, considered to be 18 years of age and over, the body begins to slow down. Changes occur, including thinning hair and body shape modifications. Sometimes old age is added to the life cycle stages. In developed countries the average life expectancy is 77 to 80 years. A few people live for more than 100 years. Life cycles are thus complex and show immense variation across species.

Light, Speed of

The physical qualities of light have always been important, but its speed has been difficult to measure. Light is the fastest known physical phenomenon, so it took the development of modern timing equipment to be able to measure it. The early civilizations, such as that of the ancient Greeks, tried to quantify light but found its qualities elusive. It was only in 1973 that the speed of light in a vacuum was accepted at the current value of 299,792,458 meters per second (m/s).

One of the first observed facts about light was that it was faster than sound. When something produced both a loud sound and a bright light, such as a cannon firing, the light always reached the observer before the sound. The difficulty trying to quantify this difference was the huge difference in the speed of the two phenomena and the lack of good clocks. Sound has a speed of 331.3 m/s (at 0^0 C, 0% humidity, and 1 atmosphere of pressure) while light goes at 299,792,458 m/s. To early observers light seemed to travel instantaneously. For many centuries the speed of light was a philosophical concept, and there were debates between those who believed it had an infinite speed and those who felt it had to be finite.

It was the invention of more accurate clocks that help generate the first realistic calculation of the speed of light. One of the first experiments to yield a rough estimate was made by Ole Christensen Roemer in 1676, who used the orbital motion of Jupiter's moon Io to make his measurement. By recording the exact moment Io entered Jupiter's shadow when Jupiter was closest to Earth and comparing that time to the time many months later when Jupiter was a known distance farther from Earth, he calculated a speed of 220,000,000 m/s for light. In 1728, this observed estimate was improved by James Bradley, who measured the apparent motion of stars at different times as compared to the speed of Earth in its orbit. His calculation of 298,000,000 m/s was accepted as the more accurate value.

As clocks and clockwork mechanisms improved, it became possible to divide time into smaller and smaller segments. The first earthbound measure of the speed of light came in 1849, when Hippolyte Fizeau used a mechanical apparatus to measure the speed of light. He used a beam of light focused on a mirror several thousand meters away. By forcing the light to pass through a rotating cogwheel, he found that at a certain rotation, light would pass through the cogwheel on both its forward and return journeys. A calculation based on a combination of distance of the light source from the cogwheel, the number of teeth on the cogwheel, and the rotational speed of the cogwheel yielded a speed of 313,000,000 m/s. This type of experiment was later refined using rotating mirrors and prisms to estimate a speed of 299,796,000 m/s in 1926. It took the development of oscilloscopes with time resolution in the subnanosecond range to further refine this number by measuring the delay of a light pulse from a laser or LED.

One of the interesting behaviors of light is that its observed speed lowers when it passes though media other than a vacuum. The refraction of light as it passes from air to water is a visible manifestation of the slowing of light as it moves into a denser medium. This has led scientists to explore the concept of "slow light" by increasing the index of refraction of various media. It is possible to increase the path that photons must take through a medium by using specialized conditions such as a Bose-Einstein condensate. Scientists have succeeded in slowing the measurable apparent speed of light to less than 1 m/s.

Since 1983 the speed of light has been treated as a defined constant, with refinement of its present value by further experimentation not needed. As a constant it functions as an absolute measure of distance (1 meter = the path traveled by light in 1/299,792,458 of a second), which has allowed for finer and finer descriptions of the velocity of objects as time measurement tools have improved.

Logical Depth

The time necessary to generate an object, given a concise description of it, is a factor that intuitively plays an important role when we assess the value of this object. We are inclined to consider an object valuable if we believe that a long sequence of rather difficult actions has led to its existence. It is, thus, a promising idea to use the length of the process in which an object has been generated as an indicator of its complexity, on which indication we then base our assessment of its value. The measure of logical (or algorithmic) depth brings this reasoning into a mathematical form. It was introduced, in the 1980s, by Charles H. Bennett, a physicist and computer scientist doing research at IBM. Along with being one of the founders of quantum computing, Bennett is also among the most important contributors to the structural science of complexity.

Bennett's definition of logical depth is based on central ideas of algorithmic information theory. The algorithmic information content of a string of binary digits (bits) is, broadly speaking, equal to the bit length of the shortest computer program that, if run on a certain type of computing machine (a universal Turing machine), outputs this string and then halts. Such a program is the most concise algorithmic description of the bit string. If this string can, again, be interpreted as the digital representation of an object (e.g., as containing a detailed account of parameters of a physical system at a certain time), then the shortest program outputting the string encodes the algorithmically most economical hypothesis about the causal history of the digitally represented object.

Bennett defines, in its simplest version, the logical depth of an object represented by a binary string as the run time of the shortest program that outputs the binary string and then stops; this run time is measured in execution steps of the program on a universal Turing machine. A long time that elapsed in the real-world generation of an object does not correspond necessarily to a logically deep time: If, in a long period of real time, there did not occur many events that contribute to the generation of the object, this stretch can be summarized by a few steps in the simulated causal history of the object. Thus, a logically deep object is one whose simulation on a computer proceeds slowly when the shortest program outputting its digital representation is run. In contrast, logically shallow objects are either very regular objects that can be simulated by short and fast programs or very irregular objects that can be simulated by incompressibly long and fast programs. Under the general constraint, stated by the second law of thermodynamics, on the possible growth of order in physical systems, a fast increase of order, measured by logical depth, is very improbable.

From an information-theoretical perspective, the logical depth of an object is not equal to the Shannon entropy of its digital representation, given a probability distribution of the binary digits. It is equal to the number of operations necessary to generate an object starting from its most concise description. These operations can, at least principally, be reconstructed if we know the digital representation of the object and search for the most concise program that outputs this representation and then halts. Logical depth is, thus, correlated with the redundancy in the causal history of the object, that is, with the difference in the number of bits between an explicit digital representation of the generation of the object and the shortest program that outputs the digital representation of this object and then stops.

The simple definition of logical depth given above is, however, not robust enough. If, for example, a program that generates the digital representation of an object much faster than the shortest program is just a few bits longer than the latter, the exclusive focus of logical depth on the minimum length program leads astray. The simplest solution to this problem is to define a mean logical depth of an object on the base of a rate of exchange between run time and program size. Such a rate of exchange must guarantee that, whereas short and fast programs outputting the digital representation of the object contribute most to its logical depth, long and slow programs contribute least. In calculating the average run time of all programs that output the digital representation of an object, the shorter and the faster the program that generates the desired output, the higher its run time must be weighted.

Longevity

Longevity can be defined as either a duration or a life span. Although the term might bring to mind the time spent by a living being in a situation, such as a job or living, the term can also be seen as much more. The length of an occurrence, or its longevity, can be measured in various ways. It can be measured in clock time, which measures all occurrences according to the same scale, such as a 24-hour day, separated into durations of equal size; or it can be measured relatively, as compared with the longevity of another event. It can be accurate according to the clock, or it can be seen in terms of perceived duration, also known as social time.

Measuring longevity, or the duration of an event or occurrence, has changed as the methods of accurately depicting the passage of time have enabled its division into smaller and smaller intervals. Time was once measured by passages of the sun or recurrences of events, such as seasons or the appearance of a star in the sky. Time now can be measured in increments far shorter than a second.

Measuring time in relation to another occurrence, such as a natural event, enables one to better comprehend longevity. However, recording and communicating such a duration to others requires their awareness of the relative measuring stick. The advent of the calendar, whether cyclic or linear, solar or lunar, enabled the consistent measuring of longevity according to a predetermined scale. Once this became possible, one could accurately date to the year, as defined by that calendar, a person's life span or the duration of an event. However, because a variety of calendric measurements coexisted, the definition of a year could vary greatly, causing inaccuracies in comparing longevities over the eons based on the generic term *year.*

The advent of the clock, which first determined time by the hour (the shortest interval that could then be measured with reasonable accuracy), enabled one to define the longevity of shorter events, such as meetings or the time of prayers, with the result that events could be more closely defined. However, again there was the difference in the length of hour, whether it was solar or "of the clock." Therefore, the hour of the day would have to be defined as clock time when stating a time; this is the basis for the term *o'clock,* meaning "of the clock," as opposed to a time based on another measuring system of the hours.

When examining longevity, one must look not only at the number but also the measuring system used at the time the number was created. In Biblical times, for example, longevity of life, if considered by the same time spans used today, might seem extremely long. However, when examining the length of a year in the times written about, one might determine that a year's length was much shorter than that measured today by the Gregorian calendar.

Without a standard measure, duration is notoriously subjective. An hour spent, for example, at a baseball game can seem to be much briefer than an hour spent in a dentist chair, and thus the longevity of these events, while they appear the same when measured by the standard measurements, seem to differ greatly to those experiencing them

The ability, and desire, to measure longevity is an essentially human trait. By knowing how long it takes for a plant to grow, or the length of time a dog lives as compared to a fish or hamster, humans gain a degree of control over the environment. A growing dependence on clock and calendar time has led to increased desires to measure more by these standards. Although society has benefited from a standardized method of measuring longevity, the existence of the method has also led to more of a dependence on such measurements. Actual time is becoming more important than perceived or social time.

LONGITUDE

Longitude is a geographical measurement that describes the position east or west of the prime meridian for a given location. On maps, longitude is illustrated by vertical lines called meridians of longitude. Unlike parallel latitudinal lines, meridians of longitude all intersect at the north and south poles. Using longitude measurements for east and west along with latitude measurements for north and south, the location of any place on the earth can be precisely described. While the equator provided the logical starting point for latitudinal measurements, there was no such obvious place for measuring longitude. Eventually the Greenwich Meridian—on which the original British Royal Observatory was located—was internationally accepted as the prime meridian. In relation to time, longitude corresponds directly to the local time of any location and is the basis for time zone divisions.

The concept of longitude originated in ancient Greece, but the quest for accurate measurement of longitude continued until modern times. While many methods were proposed and attempted for calculating longitude, the most significant development came with the production of the first highly reliable mechanical clocks. These enabled travelers to compare the time of a known location with the observed local time in order to calculate their longitude on land or at sea. Modern satellite technology now enables precise latitude and longitude to be calculated using the global positioning system (GPS).

Longitude is closely related to time, because the local time of any place on the earth is directly relative to its longitude. Each of the earth's 24 time zones represents a section 15° wide in longitude, the distance over which local time changes by one hour (1/24th of 360°). The relationship is also historical; the need for an accurate way of finding longitude, especially while navigating at sea, was a primary driving force in the advancement of timekeeping technology.

Longitude was used at least as early as 300 BCE in ancient Greece. In the 2nd century CE, Claudius Ptolemy published *Geography,* one of the earliest developed mathematical works concerning latitude and longitude, in which he discussed an earlier theory of Hipparchus for figuring longitude. Recognizing that longitude could be calculated by observing the same event in two places and comparing the local time of each, Hipparchus proposed that lunar eclipses could be used for this purpose. The soundness of this theory was outweighed by the fact that sundials, the only available timekeeping devices, would not work well when observing something that occurs only at night.

After centuries with no scientific advancements, in 1514 Johann Werner surmised a new theory for finding longitude: the lunar distance method. Werner proposed that longitude could be found by precise comparisons of the moon's apparent position relative to the stars. This method had its problems, but with necessary observation data it had potential. Precisely for the gathering of such data, the Royal Observatory was founded in Greenwich, England, in 1676.

In an age that depended upon maritime travel, the need for more accurate navigation became urgent, prompting several European countries to offer generous rewards for anyone who made breakthrough discoveries toward calculating longitude. John Harrison received the largest of such rewards ever given by Great Britain in 1770 CE for his invention of a highly accurate portable timekeeper called a chronometer. The chronometer enabled mariners to use a simpler, more accurate method of finding longitude. A traveler could compare the observed local time at noon with the time of a known location kept on a chronometer; the difference in time told the difference in longitude between the two places. With so much data already available in the almanacs published by the Greenwich Observatory, it was the natural location to which chronometers were set, and the longitude at which it was located later became the prime meridian for the entire world. The chronometer method for identifying longitude remained standard until more advanced technology replaced it in the 20th century—first radio based systems, then GPS satellites.

LUCRETIUS (C. 99–55 BCE)

Titus Lucretius Carus was a Roman poet and philosopher who is best remembered for his comprehensive epic *On the Nature of Things.* This remarkable work offered a dynamic worldview that departed significantly from the Aristotelian interpretation of this universe, life forms on earth, and the place our human species occupies within nature. Because his ideas differed greatly from those of the Greek thinker, Lucretius was not taken seriously by his contemporaries. In fact, his provocative thoughts on time, change, and reality would not be appreciated by scholars until his lost manuscripts were revived from philosophical oblivion during the Renaissance.

Aristotle had presented a geostatic and geocentric model of the universe. He separated the ethereal heavens from our material planet and claimed that the finite but eternal spherical cosmos is enclosed by a fixed ceiling of stars, each star equidistant from the earth. For him, both terrestrial linear motion and celestial circular motion are caused by the existence of the Unmoved Mover beyond the stars; this perfect entity of reflecting thought is the ultimate object that all desiring things attempt to emulate in terms of their development from potentiality to actuality. Within his philosophical system, Aristotle taught that species are eternally fixed, with the human animal occupying the highest position in a static ladder of planetary organisms. Lucretius boldly challenged each of these basic Aristotelian assumptions.

Rejecting religious beliefs and ignorant superstitions, but indebted to the earlier thoughts of Epicurus, Lucretius presented a strictly naturalistic interpretation of and explanation for the existence of this eternal and infinite universe. He argued that endless reality consists only of material atoms and the void, there being no difference in makeup between celestial and terrestrial objects; thus, his natural philosophy taught the cosmic unity of all existence. Furthermore, Lucretius saw this dynamic universe as a creative process within which, over time, material atoms combine by chance to form an infinite number of stars, planets, and organisms. As a thoroughgoing naturalist, he taught that all objects and events are a part of an ongoing material reality that has no center, design, purpose, or goal.

For Lucretius, if there are immortal gods somewhere in this universe, then they have no interest in human existence. Nevertheless, with his powerful imagination, he speculated that life forms and intelligent beings (perhaps beings even superior to humans) exist elsewhere on other worlds throughout the cosmos. Within this dynamic worldview, Lucretius glimpsed the forthcoming evolutionary framework. He held that, over time, the material earth itself gave birth to those plants and animals that now inhabit this planet, including our own species. Furthermore, for him, organic history is full of both creativity and extinction.

With exceptional insight, Lucretius outlined the sociocultural development of the human animal. In their prehistoric state, our naked but robust ancestors lived in caves and subsisted on pears, acorns, and berries. They wandered through the forests and woodlands searching for wild beasts (e.g., boars, lions, and panthers) with clubs and stones. Later, our ancestors wore animal skins, learned to use fire, and lived in nomadic hunting/gathering societies that waged war. Over time, humans even developed the use of symbolic language as articulate speech. With the emergence of agriculture, they learned to cultivate plants and domesticate animals. Eventually, civilizations appeared and flourished, with people living in cities, using metals (first copper, then bronze, and later, iron), and developing art, law, and religion.

Lucretius offered penetrating insights into the nature of our universe and the history of life on earth that far surpassed the cosmology of Aristotle. He enlightened later thinkers with his bold speculations, influencing several recent major philosophers from Herbert Spencer and Henri Bergson to Alfred North Whitehead and Pierre Teilhard de

Chardin. This is an impressive testament to Lucretius, whose astounding vision was first presented over 2,000 years ago.

Luther, Martin (1483–1546)

Martin Luther, a German priest, monk, and theologian, was among the leading figures of the Reformation. As part of the exceptional role he played in the history of religion during his lifetime, Luther added some new thoughts to Christian thinking about time.

He was born to a burgher family. From approximately 1490 onward, Luther attended a variety of schools. In 1501, he began his basic philosophical studies at the University of Erfurt; these basic studies were required for further studies in theology, medicine, or law. In the spring, Luther decided to follow his father's wishes and began to study law. On July 2, 1505, he experienced a severe thunderstorm and, believing himself to be in mortal danger, vowed to become a monk if he survived. Fifteen days later, he joined an Augustinian monastery in Erfurt. In spring 1507, he received his ordination to the priesthood. In the same year, also in Erfurt, he began his studies of theology, which were to continue later in Wittenberg. From November 1509 to April 1510, he traveled to Rome on behalf of the brotherhood. In 1512, he received his doctorate in theology, was appointed as professor of theology at the University of Wittenberg, and became subprior of the monastery in Wittenberg.

On October 31, 1517, he sent 95 theses about indulgences to archbishop Albrecht of Mainz and other theologians with the demand to discuss them. In these theses, Luther proclaimed that the selling of indulgences as it was practiced at this time was not the right way to salvation. The theses were followed by turmoil in the church. Luther was asked to abjure his theses, but he insisted on having a disputation. In 1518, he wrote to Pope Leo X to inform him better of the situation. The answer was the issuing of a Papal Bull in 1520 in which 41 of Luther's theses were called heretical and which contained a warning that Luther risked excommunication.

In consequence of his refusal to recant, Luther was excommunicated from the church on January 3, 1521. In May 1521, he was ordered to the Reichstag zu Worms (Diet of Worms) with the promise of free passage on the way. Luther refused once again to deny his claims without their falsification by arguments from the Bible. On his way back to Wittenberg, Luther was kidnapped by men of his own sovereign and supporter, Frederick III of Saxony, and brought to the Wartburg in Eisenach to be kept there hidden in safety. In this exile, Luther translated the New Testament into German.

Luther stayed in Eisenach until March 1522, when he returned to Wittenberg to moderate the movement for religious reform, which was initiated by Andreas Karlstadt and which exceeded Luther's goals. In the following years, the reform movement quickly spread, first to Saxony and later to other parts of Europe. From 1524 to 1526, peasants whose discontent had been fueled by Luther's writings revolted. After attempting to pacify the peasants, he took a position on the side of the sovereigns in this evolving war. In 1525, he married Katharina von Bora, a former nun. Over the years, there were many debates, especially with Müntzer, Karlstadt, and Zwingli, on the right course of the reformation and its theological contents.

At the Reichstag zu Speyer (Diet of Speyer) in 1529, the Catholic members of the diet wanted to cancel the provisional acceptance of the reformed members of the diet. The protestation against this decision established the name "Protestants." During the Reichstag zu Augsburg, the reformed parties presented their confession, the so-called Confession of Augsburg (*Confessio Augustana*), which was composed by Luther's friend Philipp Melanchthon. In 1534, Luther's translation of the Old Testament was published.

During the following years Luther's state of health deteriorated, although he stayed head of the German reformation and was often called upon in case of conflicts in theological disputes as well as in worldly matters. In February 1546, he traveled (although seriously ill) from Wittenberg to Eisleben to mediate in a conflict threatening the livelihood of his siblings' families. He died there, after successfully settling the matter, on February 18, 1546.

Luther's view of time is always eschatological. Influenced by Pauline theology, two of the bases of his view of time are the virtues of *fides* (belief) and *spes* (hope). The difference between these two virtues is practically irrelevant for Luther's concept. The Christian hope and belief aim for a future in which the realm of God is present. The suffering in this world for the Christian has two parts: first, the suffering every human has to endure due to illness and misfortune, and second, the worry about life, because every real Christian knows himself to be a sinner. In Luther's view, the life of the Christian is justified because he endures the second suffering. In his view, Christ gives the promise that the realm of God is open for the people who are worrying about their sins.

But the object of Christian hope, the realm of God, cannot be perceived during one's lifetime but stays hidden from the physical world. According to Luther's belief, the exact design of the realm of God cannot be imagined by a human being. It will always stay hidden from the searcher's mind and eyes. But in his view, it is possible that hell and heaven are not worldly places in real time and space but exist only within the soul. According to this line of thinking, every believer's conscience might be the place of final judgment and hell. Therefore, resurrection might take place directly after every individual's death, because it would not be bound to the dimension of time as humanity understands it. Here, the influence of Saint Augustine of Hippo is obvious. For Augustine, time exists only within the soul, because neither past nor future exist in the present, while the present itself has no extent.

Luther does not subscribe to the idea, however, that to believe is a pure decision of the individual. Following the tradition of Paul and Augustine, he is convinced that God manifests the true belief in people. In this way, he pleads for a kind of predestination. Belief is to be understood as a gift given by God to humanity. This gives humankind also a kind of freedom of conscience and belief, because its belief is not made by itself. But in the end, rational thinking is not an adequate means to fully understand the working of God.

Lydgate, John (c. 1371–c. 1449)

John Lydgate was a poet and monk of the Benedictine abbey of Bury St. Edmunds in Suffolk, England. Adept at writing for a variety of patrons and purposes and in a wide range of styles, he penned short devotional lyrics as well as vast moralistic tomes running to tens of thousands of lines each. Although after the Protestant Reformation, his reputation waned, during the 15th century Lydgate was the most popular didactic poet in England. Some of his works survive in more late-medieval manuscript copies than even certain poems by Geoffrey Chaucer, whom modern readers generally consider to be Lydgate's superior as a poet. The longwinded didacticism of "the Monk of Bury" has left him open to the frequent charge of tediousness. This and the apparent irregularity of his meter (in comparison with Chaucer's) drew widespread critical disparagement from the 19th to well into the 20th century. In the context of discussions about time, however, Lydgate is interesting both because of his attitudes toward the history of civilizations and because of his place in the history of literature.

Born around 1371, the poet apparently followed customary practice among medieval monks by taking his surname from his place of birth, in this case what is now the modern village of Lidgate in the county of Suffolk. He entered St. Edmund's Abbey as a teenager and was sent to the University of Oxford for further training in theology. Although he was a Benedictine monk, he spent plenty of time in the world outside the cloister and, because of his skill as a moralistic versifier, garnered the patronage—essential to premodern poets—of some of the most illustrious figures of his day. These included Henry V (whom he evidently met at Oxford), Henry VI, and Humphrey, Duke of Gloucester, among others; they were either the recipients of or the guiding influences behind some of Lydgate's longest productions. For example, *The Troy Book* (c. 1420–1422) addresses Henry V's victory over the French at Agincourt, while *The Lives of Saints Edmund and Fremund* was written to commemorate Henry VI's Christmastide sojourn at St. Edmund's in 1433–1434. The immense *Fall of Princes* (c. 1431–1439), Lydgate's longest work at over 36,000 lines, was commissioned by Duke Humphrey.

Both in his so-called courtly works, written for royal or aristocratic patrons, and in his less ambitious poems, Lydgate was chiefly concerned to praise God and his saints and remind his readers of their own dependence upon them. As creatures living out their lives in earthly time, Lydgate's readers were expected to conform their wills to Christ's in eternity and to prepare their souls for final judgment at his hands.

Until late in the 20th century, literary critics dazzled by Chaucer and other contemporary poets like William Langland and the anonymous (presumed) author of *Pearl* and *Sir Gawain and the Green Knight* found little to commend in the writings of a derivative, digression-prone moralist. Since the 1980s, however, scholars have returned to literary history with a keen interest in the relationship between writers and the sociopolitical conditions of their times. Much has been done of late to salvage modern understanding of his importance by situating Lydgate in the contexts of contemporary court politics and religious devotion.

To broach the topic of Lydgate and time, however, is to return to older critical discussions that dismissed 15th-century English literature as little more than an artistically arid interim between the ages of Chaucer and Spenser (or, alternatively, Shakespeare). In some respects, Lydgate does indeed seem self-consciously traditional. He affirmed pious orthodoxy at a time when the church in 15th-century England sought to curtail speculation on religious matters. Moreover, he appears to confirm modern scholars' suspicion that medieval writers lacked a sense of historical change, a basic awareness that customs, religious rituals, and dress did not remain the same over the course of 2,000 years. Finally, Lydgate was seemingly unaware of, or hostile to, the advances in humanistic thought characteristic of the Renaissance taking place in the Italy of his day.

Even so, the Benedictine poet had clear notions about time and history, whether or not those notions were reactionary. His interest in classical antiquity was real. It is evident in his long historical romances, *The Siege of Thebes* (early 1420s) and *The Troy Book,* as well as in *The Fall of Princes,* a series of didactic vignettes about illustrious biblical, classical, and medieval personages who rose to great heights of prosperity only to suffer abrupt downfalls. Yet Lydgate was no archaeologist: He was not concerned to investigate the distant past as it "really" unfolded. On the contrary, in his work he often rails against those pagan customs that he judges to be irreconcilable with Christianity.

To say that he therefore lacked a historical sensibility, however, is to assume that he should have shared the modern historian's dispassionate interest in learning exactly what happened and where and why it did. His reasons for studying antiquity were very different. He used ancient narrative materials such as the Troy and Thebes legends partly because he had a bookish interest in old stories, partly to find evidence for what he believed were eternally valid moral principles, and partly for the purpose of addressing political concerns that were current in the England of his own day. In unfolding the tragedies of Thebes with unstinting attention to their violence, he may have wished, as some scholars have argued recently, not so much to condemn the "ancient" and the "pagan" out of hand as to warn English kings and princes against the recurrent perils of empire building in all times and places.

Admirable attempts were made in the 1950s (by Walter Schirmer) and 1960s (by Alain Renoir) to treat Lydgate as a harbinger of English Renaissance humanism. Derek Pearsall's landmark study of the poet (1970) instead argued, without apology, that the Monk of Bury was much the product of his time and place. Debate continues apace, with ever more energetic scholarship focusing on the very meaning of formerly unexamined terms like *medieval, conventional,* and *humanistic.* To this ongoing conversation scholars like Lee Patterson, David Lawton, Paul Strohm, James Simpson, and others have made valuable contributions. All agree that Lydgate was a more active thinker and a more purposeful commentator on history than earlier scholars suspected.

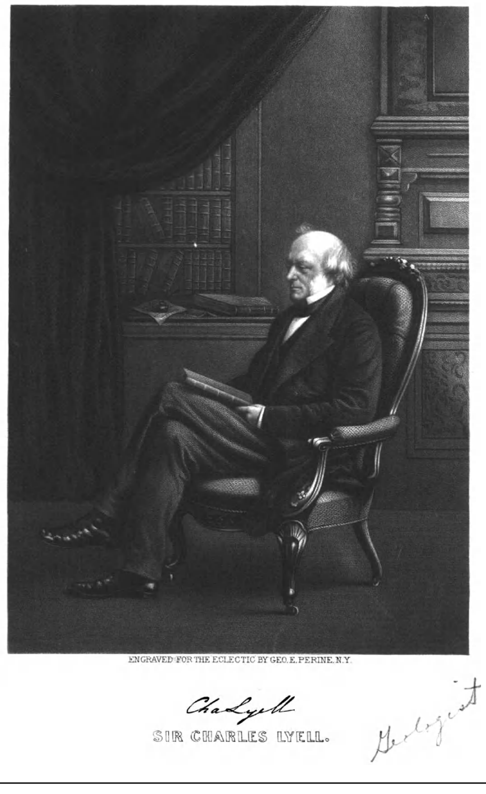
Lyell, Charles (1797–1875)

Charles Lyell is widely regarded as one of history's most notable and influential scientists. His work in historical geology helped cement our understanding of the earth's formation. Yet, for all Lyell's efforts to gain acceptance and recognition of geological theory and the emerging science of historical geology, it is his impact on Darwinian evolution and the understanding of humanity's place in time that is arguably his greatest achievement.

Born in Scotland in 1797, Lyell took an early interest in nature studies, eventually focusing on geology for his career path. Inspired by geologist James Hutton's idea of *uniformitarianism,* Lyell supported the idea that Earth's geological elements are continually affected by slow processes of change (erosion, uplift, etc.) and always have been. Between 1830 and 1833, he summarized many of his emerging ideas in his chief work, *Principles of Geology,* which ultimately influenced



Lyell's version of geology came to be known as uniformitarianism because of his insistence that the processes that alter the earth are uniform through time.

scientists not only in geology but also in the fields of archaeology and biology as well. Lyell continued to publish his findings, which were widely read and admired by his scientific peers. He was knighted in 1848 in recognition of his many contributions to science.

Charles Lyell's primary legacy revolves around uniformitarianism and the earth's age. Whereas Hutton formalized uniformitarianism, Lyell arguably became its most influential proponent. Lyell's research and argumentation helped cement the idea that the earth's landscapes took eons to form, a thought in stark contrast to Archbishop James Ussher's Bible-based estimate that the planet was formed approximately 6,000 years ago. The premise that billions of years instead of thousands were required to form Earth, the solar system, and the entire universe was radical in the extreme and challenged doctrines whose authority lay in religious scripture. Lyell helped revolutionize not only geological thought but scientific thought in general by helping scholars look beyond conventional ideas of time and change.

Lyell's *Principles of Geology* made an impression on countless scientists, including Charles Darwin. For Darwin, Lyell's arguments supported the idea that organisms, including humans, needed as much time to change as rivers needed to carve out canyons and mountains needed to rise and fall. Such a conceptualization made Darwin's evolutionary ideas appear all the more plausible. Consequently, Lyell, though initially hesitant to embrace the ideas of evolution of organisms, provided Darwin with direction. The ensuing shift in humanity's understanding of time, the pace at which events unfold in the natural world, and our own place in the natural order is due in part to Lyell's contribution, which cannot be overvalued.

Lysenko, Trofim D. (1898–1976)

A biologist and agronomist, Trofim Denisovich Lysenko was director of the Institute of Genetics in the Academy of Sciences in the Soviet Union under the regime of Joseph Stalin. To the public he was portrayed as a heroic example of the self-educated peasant. Although the theories he espoused were based largely on misunderstandings of genetics and scientific principles, the exercise of political influence and power enabled Lysenko to hold sway over biological research in the Soviet Union for decades. Lysenko's genetic theories rejected the theories of Gregor Mendel; they were the result of blending a superficial understanding of the theories of Jean Baptistede Lamarck with specific selections from Charles Darwin's theories that would support Lysenko's latest interpretations of inheritance.

Born near Poltava in the Ukraine, the son of a poor Russian farmer, Lysenko's first employment was as a gardener. In 1921, he studied at the Uman School of Horticulture. Shortly thereafter, he was chosen for the Belaya Tserkov Selection Station, and in 1925 he received a doctorate at the Kiev Agricultural Institute. Lysenko was highly interested in the theories of Ivan Vladimirovich Michurin, who taught that the environment is directly responsible for the development of hybrids that are very different from their parents. By controlling the environment, a breeder can select the type of hybrid to be developed. Individuals are highly plastic and not limited to the genetics of their parents. The results are then under the authority of the breeder. Although Michurin claimed many successful results, no one else seemed able to replicate his outcomes.

While working at an agricultural experimental station in Azerbaijan in 1927, Lysenko came up with the idea that fields could be fertilized by planting a winter crop of field peas. The field peas would then provide livestock with forage through the winter. Lysenko claimed that the use of chemical fertilizer did little to improve crop yield. Chemical fertilizers were successful the first year, but failed in succeeding years in areas of poor soil fertility.

This was the beginning of a career that would last until 1964. Each of Lysenko's failures would be rapidly followed by a new stunning success by the "peasant genius," as reported in the Soviet press.

In the Soviet Union, the long winters required that seeds survive long cold periods. Lysenko claimed that cooling the seeds before planting increased their strength and therefore the yield of the next crop. Lysenko selected spring wheat with a short "stage of vernalization" (exposure to cold) and a long "light stage," which he then crossed with wheat of a longer stage of vernalization and a short light stage. This led to increased yields and new varieties of grain. Largely as a result of the adulatory reports of this experiment by the Soviet press, Lysenko became editor in 1935 of his own agricultural journal, called *Vernalization*. His failures were not reported but led rather to new claims of success. His only real success, however, was his popularity among Soviet farmers, who were unenthusiastic about Soviet agriculture in the early 1930s. While most of his experiments ultimately hurt the Soviet farmer, because he was one of their own, his popularity remained intact. This served the needs of the Soviet government.

Lysenko was most noted for his criticism of the genetic theories of Mendel, Morgan, and Weisman, which he saw as antiscientific, decadent, and metaphysical. Lysenko set out to save science founded upon dialectical materialism from religious dogmatism masquerading as empirical science. His claim was that these genetic theories made the same errors as those of Thomas Malthus, who was exposed by both Karl Marx and Friedrich Engels for using deductive logic instead of empirical science.

Lysenko made the following argument: Intraspecies competition would only weaken the species in its adaptation to a changing environment. Morgan-Mendel genetics would be too slow to allow any species to survive in the real world; fixity of species was the core of the metaphysical superstition of the Morgan-Mendel school. Darwin proved that species do adapt to their environment and, in the process, species evolve into new species. Morgan-Mendel's ilk destroyed the insights of Darwin. According to them, genes and chromosomes that were fixed and passed on from generation to generation could not change fast enough to prevent extinction. This is why genetic theory would be metaphysical and not scientific. It created a dilemma that could only be avoided by introducing mutations or genes that would randomly make mistakes in the next generation. Furthermore, they said that most mutations were lethal, making all life on this planet impossible. Their only solution was divine intervention. Thus Morgan-Mendel genetics introduced religious dogmatism as a replacement for honest science. Lysenko claimed to merge Marx and Darwin; in fact he was closer to Lamarck than either Marx or Darwin.

By 1927, the Soviet Union had survived the First World War, revolution, civil war, invasion by 18 powerful nations, an economy in ruins, famine, isolation, and a desperate need for solutions. Simple remedies for complex problems were more attractive than more complicated solutions. The Soviet Union emerged from chaos with a political structure that was both rigid and bureaucratic. The Communist Party's tight control over all aspects of society led to fear of innovative ideas out of step with party directives among the top party leadership. The scientific community was particularly controlled in an inflexible and mechanical way. Science was defined as part of a larger global class struggle. There were two kinds of science: bourgeois capitalist science and revolutionary proletarian science guided by dialectical materialism.

The Communist Party used hero worship as a way to gain support for its policies. Lysenko, being a peasant himself, was a hero figure. When Russian farmers were resisting forced collectivization, both Stalin and the resisting peasants loved Lysenko. Lysenko was the son of a poor farmer who used commonsense arguments. His lack of understanding of genetics proved to most farmers that he had more connection to the land than most professors who had been "corrupted by Western ideas." With this support, he could make the case for genetics as part of an imperialist conspiracy to destroy true science.

Lysenko used anti-intellectual values and the support of a coercive government to secure his tight control over agricultural science and biology for many years. By early in the Cold War, his control was complete. The resolution in 1948 of the Lenin Academy of Agricultural Sciences of the USSR made any disagreement with Lysenko's findings illegal. Textbooks at all levels of education did not even mention Mendel's genetics. As a result, many serious biologists were exiled, tortured, imprisoned, murdered by the government, or committed suicide. With Stalin's death in 1953, there was a slight thaw in Soviet biology, and in 1956, more criticism of Lysenko's theories became possible. Nikita Khrushchev offered some protection. However, Lysenko resigned as president of the Academy of Agricultural Sciences in 1954, and in 1956 his resignation as president of the All-Union Academy of Agricultural Sciences was announced. In 1965 he was removed as director of the Institute of Genetics, and Lysenko was officially blamed for much of the failure of farms in the Soviet Union. Trofim Lysenko died in 1976.

M

Mach, Ernst (1838–1916)

Perhaps best known as a founder of the field of philosophy of science, in which he held a chair at the University of Vienna, the Austrian physicist, mathematician, philosopher, and science historian Ernst Mach also had a major influence on the emerging discipline of physiological psychology as well as on the development of physics itself. Albert Einstein would later credit Mach's critique of Newtonian concepts of absolute time and space as a decisive influence on the development of relativity theory.

A prominent element in Mach's thought is antimechanism, or the refusal to accept the doctrine that reality, including psychic phenomena, consists essentially of matter in motion. Along with naturalism, the principle that nothing exists beyond nature, it was largely Mach's embrace of Darwinian evolution that shaped his ideas. According to Mach, human culture, science, mind, and the senses have an evolutionary history, and indeed knowledge itself is a product of biological evolution. The earliest organisms responded to simple experience, thereby constructing an elementary picture of the primordial world; out of these first interactions, more complex understandings emerged, forming innate capacities in our remote ancestors that gradually developed through adaptation into increasingly elaborate constructions. The acquisition of memory permitted greater scope for awareness of spatiotemporal relations than what is given directly to the senses; much later on, memory was greatly extended by the capacity to communicate culturally. For Mach, scientific activity is not only the product of biological evolution; it also serves to advance the evolutionary process by giving rise to further adaptations as new data are confronted and understood. From among all available ideas, whether derived logically or from dreams or fantasy, scientists select those theories that best fit the data. In this way science proceeds, as does biological evolution, by a process of selection.

After earning a degree in physics, Mach undertook studies in anatomy, physiology, and chemistry at the medical school of the University of Vienna, where he later designed and taught a course in physics for medical students. From the pioneering work of Gustav Fechner, the founder of experimental psychology, Mach learned that there are quantifiable thresholds of perception, in other words, that sensations can be measured. Thus, a mathematical relationship exists between the psychological realm and the physical. Here lay the key to an experimental methodology that would produce, in studies by Mach and his contemporaries and up to the present day, significant advances in the psychology of perception, including color, sound, space, and time.

Today Mach's name is commonly associated with measurements of the velocity of sound. The development in the mid-19th century of more powerful guns and cannons had led to the production of bullets and shells that traveled at speeds greater than that of sound vibrations. Mach's research into supersonic motion, published in 1877, helped to establish the field of modern aerodynamics; the Mach number, still in constant use by engineers, is the ratio of the speed of a projectile to the speed of sound.

Mach's investigations into optical phenomena included the discovery of so-called Mach bands, an effect of contrast perception that creates the illusion of narrow light and dark bands at the boundaries of contrasting areas. Of greater significance is Mach's more fundamental insight that *perception itself is always relational;* that is, we perceive not the world itself, but relations between sensations. Our senses have evolved to perceive contrasts between stimuli. It is the interaction of a new experience with the residue of a previous experience, or the difference between successive sensations, that forms the basis of perception.

Machiavelli, Niccolò (1469–1527)

Niccolò Machiavelli was a Florentine diplomat, political theorist, historian, and poet. He was politically active in the courts of Louis XII of France, Cesare Borgia, Maximilian I, and Pope Julius II. After the return to power of the Medici in Florence in 1512, Machiavelli underwent banishment and withdrawal to Sant' Andrea, where he wrote his two major political works: *The Prince* (*Il Principe,* 1513), and *Discourses on the First Ten Books of Titus Livy* (*Discorsi sopra la prima deca di Tito Livio,* 1513–1522). These political writings present themselves as political counsel. They deal mainly with the possibilities for the lasting stabilization and self-preservation of polities. The theme of time emerges against the background of this practical problem. Machiavelli's analysis of history focuses on the way different factors are persistent or variable with time. He formulates advice for different time frames and deals with the correct handling of the opportunities and dangers of time as a factor of political action.

The Prince

Machiavelli's project can be understood as an answer to the then current political crisis of an Italy that was splintered into city-states. *The Prince* is his most influential work. Formally the work follows in the Middle Ages tradition of "mirrors for princes" that deal with the presentation of the kingly virtues. But Machiavelli breaks with the tradition in content. Instead of a normative orientation around Aristotelian virtue ethics and the Christian natural law tradition, he lays out a series of rules for political cunning. Not the ideal, but rather the actual determines Machiavelli's advice. Most of this advice relates in particular to the acquisition and maintenance of power by a new prince. Machiavelli's achievements in *The Prince* testify thereby to his efforts to recommend himself to the Medici for reinduction into the service of the state.

The virtues (*virtù*) Machiavelli recommends for princes should not be understood as classical virtues. These would even be harmful. The prince must appear to have those virtues that are considered good, but he must also have the ability to contravene mercy, humanity, and religion. For Machiavelli, justice and political success are not connected.

This counsel, directed to the achievement and preservation of the power of the autocrat, gave Machiavelli the reputation of a "teacher of wickedness." This emancipation of politics from morality was influential in the history of ideas. The directives, focused on the preservation of the prince, provided a basis for later thought on questions of national interest and are to this day a point of reference for political realism.

The *Discourses*

The *Discourses* are a commentary by Machiavelli on the Roman histories of Titus Livy. But at the same time, he unfolds a republican theory of the state. His analysis of the history of Rome has the goal of enabling a revival of Rome's political success. Since the basic structure of the world is invariable, history can serve as a teacher in current political questions. The imitation of ancient Rome could thus be the solution to the political crisis of contemporary Italy.

Machiavelli claimed that there are particular, necessary rules in history that hold for all time. These *necessità* are not interventions into history by a god (*providentia dei*) but rather regularities comparable to natural laws. Throughout time, political events follow necessarily from particular preconditions. This compulsion can result from natural circumstances or from the actions of humans.

For Machiavelli, human nature is a constant. Humans always tend to the bad rather than to the good, and they ceaselessly follow their appetites and ambitions (*ambizione*). They are not political beings by nature but must be domesticated and cultivated by institutions. Only in the well-ordered state can they develop the necessary powers for the preservation of the polity.

Politics, Government, and Time

The connection between *The Prince* and the *Discourses* has always created difficulties for interpreters. The techniques aimed at the retention of autocratic power and the reviving of republicanism are two different, situation-dependent proposals for solving the problem of the stabilization of a polity. A consistent reading presents itself against the background of Machiavelli's conception of political time.

Human nature imprints a determinate structure on the course of history. Following the ancient historian Polybius, Machiavelli formulates a cyclical model of the forms of government. States change from a condition of order to a condition of disorder. They thereby pass through various forms of administration, from autocracy to popular government. Monarchy degenerates to tyranny, aristocracy to oligarchy, and democracy to anarchy. For Machiavelli, all of these forms of government are to be rejected, the good ones because stability is ephemeral, the degenerate forms because of their badness.

According to Machiavelli, periods of political decline require an autocrat to bring new order to the polity, because the people are not in a position to do so. The advice in *The Prince* is directed in particular to this politically effective agent (*uomo virtuoso*). But the function of the *uomo virtuoso* seems to be temporally limited. If the polity is able to maintain itself after the establishment of laws and institutions, then the republican mixed constitution is for Machiavelli the better form of government. The considerations in the *Discourses* apply to such a government.

Republics are best able to maintain their inner stability and external capabilities of expansion. In them, the prince, the nobility, and the people can govern and oversee themselves together. Republican freedom is the result of orderly conflict between the nobility and the people.

Machiavelli makes temporal continuity the criterion of success in politics. The other goals of political action are subordinated to it. The key to defense against the permanent dangers of decay and corruption is *virtù*. In Machiavelli's usage, this denotes a category of accomplishments that lead to political success. *Virtù* can be found in individuals, in a people, or in the military.

Since *virtù* cannot be inherited, the competence of a people is better than that of an autocrat as the starting condition for a stable polity. The mere continuity of a republic over generations is grounds for its precedence as a form of government. Republican freedom can be a means of achieving enduring political stability.

Virtù represents power in the fight against *Fortuna*. Opposed to *necessità, Fortuna,* often personified as a female deity, stands for unpredictability in politics. She is the irrational moment in time. Her temper can help a polity to greatness or bring about its fall. She predestines the path of human action, but not absolutely. Machiavelli sees about half of the action as being left to human skill.

Even if the arrival of *Fortuna* is uncertain, there are ways to take precautions against her. Machiavelli compares her with a raging torrent that in its times of calm allows dams to be built. But the human tendency is to not think about changing times. This idleness is a sign of lacking *virtù* and offers *Fortuna* easy prey.

On the other hand, correct *virtù* can harness *Fortuna* for political success. The goddess of fortune can appear as the bringer of favorable opportunities (*occasione*). If they are recognized and exploited, then the agent has a share in luck. Machiavelli talks of the *occasione* as hurrying by, with the hair brushed forward covering the face so as not to be recognized. If the opportunity passes by, then one tries in vain to grab it by the bald back of its head.

The contest with *Fortuna* requires a deep sense of situation and adaptiveness to actual temporal circumstances (*qualità dei tempi*). Time, writes Machiavelli, drives everything before it, and it is able to bring with it good as well as evil. But time waits for no man, and only the one who adapts to it will have luck in the long run. Republics offer here the best conditions because of the diversity of their citizens; they are more flexible and adaptable than an autocracy. The *virtù* of one person fit for one time is not likely to change when circumstances change.

However, even the degeneration of a republic cannot be stopped, only slowed. Machiavelli calls time the father of truth. The enduring badness of humanity becomes manifest and in time spoils goodness. Thus, for Machiavelli, there is a natural limit to the life of all things in the world. Decay is inherent to time.

Magdalenian Bone Calendars

A number of authors (e.g., André Leroi-Gourhan) have examined the possibility that Paleolithic engravings may have constituted a form of notation—certainly this is the case with the Azilian painted pebbles, but the name most associated with Magdalenian bone calendars is that of Alexander Marshack of Harvard's Peabody Museum. Marshack determined that certain objects of art from the late Stone Age Magdalenian, Solutrean, and Aurignacian periods of the Upper Paleolithic may have been not simply *objets d'arts* or hunting tallies but may have served as lunar calendars. The Upper Paleolithic period stretched from roughly 30,000 years ago to 10,000 years ago, with some range of variation. This was during the height of the Würm glaciation, when much of the classic "cave art" is believed to have been produced.

Although polychromatic paintings of ice age animals found on cave walls (parietal art) in southwestern France and northern Spain, most notably those of Lascaux and Altamira, are the best-known examples of Upper Paleolithic art, portable art also exists from this time. Venus figurines often are displayed as examples of Upper Paleolithic portable art, but there also are objects of unknown use. Among these are pieces that Marshack claims represent calendars or seasonal notations. These are exemplified by a piece carved in the round on an antler. This carving, when rolled out on a flat matrix, represents reindeer, snakes, and salmon. The carvings show scratches that have been taken to be arrows. Marshack showed them to locals in the area where the piece was found, and they proclaimed the scratches to be *farin sauvage,* or wild wheat. Marshack determined that because of the antlers on the deer, the exposed genitalia on one of the snakes, the appearance of a hook on the jaw of a salmon on the carving, and the wild wheat in seed head, that the carving represented a short period of time in the spring when all of these factors co-occur.

Further, Marshack believed that he had found evidence of thousands of engraved and painted notational sequences from Spain to Russia and an actual lunar calendar showing phases of the moon carved into a piece of mammoth ivory from the Ukraine. For some, the most convincing evidence comes from a 10-centimeter-long ovaloid Aurignacian antler plaque from Blanchard, Dordogne. The Blanchard plaque shows 69 round and "paisley" pocks in a complex line that snakes back and forth across its flat surface. Marshack argues that when the pock-marks are microscopically examined, it is apparent that they were made over an extended time with multiple tool points and engraving pressures. The paisleys and circles correspond to the waxing, full, and waning moons over nearly two and a half months. The snakelike arrangement of the marks appeared to be the moon's rising and setting positions to an observer facing south. Some of Marshack's claims have been seconded in recent years by Francesco d'Errico by use of a scanning electron microscope. Although a number of people remain unconvinced by Marshack's discoveries, it is undeniable that he has made a significant contribution to our understanding of Upper Paleolithic observational abilities.

Magna Carta

The Magna Carta (Latin for "Great Charter") is considered one of the most significant documents in history. First issued by King John of England in 1215, it formalizes the covenant whereby the king was compelled by the barons and the authorities of the church to make a series of promises regarding rights and privileges, thus imposing constraints on the powers of a monarchy hitherto regarded as absolute. Over the following centuries, the Magna Carta has had a strong influence not only on British constitutional history but also on the democratic development of other nations.

The signing of the Magna Carta has long been lauded as a defining moment in human history and has been cited as a touchstone of English common law by those seeking the guarantee of rights and freedoms in nations throughout the world. It is important, however, to note that the charter did not grant rights and privileges to all people in 1215. The English barons, or noblemen, and the church drafted the Magna Carta to assert their own rights and thereby check the power of the monarchy. The common people of England initially gained little. The document's prestige increased over time with the development of parliamentary government. It became a symbol for liberty and individual rights against oppressive rule.

Earlier English kings had made agreements with their barons. The Magna Carta differs in that it is the first important example of the king's subjects demanding rights and forcing him to concede. John became king in 1199 and lost little time in angering his subjects. He waged war unsuccessfully in France, which required him to raise taxes and conscript more nobles for military service than had his predecessors. He broke with feudal tradition by failing to consult with his barons on important issues. John also clashed with Pope Innocent III over the appointment of the archbishop of Canterbury. This quarrel resulted in John's excommunication from the Roman Catholic Church in 1209. Reconciliation with the church was immediately followed by additional military defeats. In 1213, the disaffected barons and clergy met and outlined a list of articles. John dismissed these twice before the barons raised an army. The king then reluctantly arranged to meet with them at Runnymede, south of London, and agree to terms.

The Magna Carta was concluded on June 19, 1215, following much squabbling. Written in Latin, as was the custom during the age, it was essentially a peace treaty. It contained a preamble and 63 articles, which were for the most part reactionary rather than revolutionary. The articles were divided into separate groups dealing with issues such as law and justice, conduct of royal officials, trade, the independence of the church, and the royal forests. The concluding articles concerned King John's loyalty to the Magna Carta and the right of the barons to challenge the king should he ignore the charter. The Magna Carta was reissued and amended a number of times in subsequent years. The vague wording of many of the articles has left considerable room for interpretation over time. Later generations interpreted clauses 39 and 40 in particular as protections of habeus corpus and trial by jury, but the reasoning has been much debated.

The stature of the Magna Carta increased over time as English lawyers and members of parliament cited it in arguing the rule of law. In addition to English common law, the charter has influenced constitutions throughout the world, including that of the United States. Four of the original copies are known to remain.

Maha-Kala (Great Time)

In the tradition of India, the creation of the universe is the purpose and significance of Maha-Kala, or Great Time. The Great Time is personified by the god Siva and his alter-ego Maha-Kala. Siva is the artistic part of creation. Maha-Kala is the power (called Pralaya or the Great Dissolution) to dissolve the universe. Destruction is necessary for creation; reproduction requires both creation and destruction. This interaction is the reproduction of nature and the cycle of birth and death. Both male and female principles are at work: The female is destructive by dissolving what is ceasing to exist into herself; the male is creative by being the source of new existence continually being created in the universe; this interaction is represented by the concept of Sankara.

Siva Maha-Kala represents the continual rebirth of the universe, which is going on continuously. Also, it is the life cycle of the universe, which is born, matures, and dies. The universe is created by Siva and destroyed by Maha-Kala. New universes are created out of the destruction of the previous universe. This then brings about the Mahadaeva, who is the deity without comparison—the Great God who is Siva.

Unity is the restorer, which is symbolized by Linga the Phallus, or Global Oneness. The linga is the erect penis of Siva, which represents the respect and meaning of life. When combined with Yoni, the symbol for the female genitals, it becomes the reproduction of the universe. Yoni is the center of all that is spiritual. Through this union of the material and the spiritual, the universe is formed.

Maha-Kala is the destroyer essence of Siva; but she is more than that. She is the force that absorbs all of creation unto her. From this material, which Maha-Kala allocates into her womb, Siva can fashion the universe once more. The destroyer is the regenerator. Through destruction, rebirth and evolution are possible. Through understandings of the nature of destruction and creation, union with true enlightenment becomes possible.

Mahayogin is the knowledge of the secrets of the universe. Because of this, Maha-Kala is the destroyer of human passions. With the annihilation of all excitement, true enlightenment is possible. With illumination, it is possible to achieve ultimate understanding and tranquility in the endless shifting cosmos and escape from the affliction and suffering of life, existence, death, and fate.

Siva Maha-Kala is also the Nataraja, the lord of dancers and the dance of creation, destruction, embodiment, liberation, and maintenance. With the invention of the cosmos, the devastation of creation is realizable. The personification of the interaction of contrary forces brings release and preservation from stagnation. Nataraja is the artistic representation of Siva Maha-Kala through dance. The dance expresses the continuing creation and destruction of the universe as a single interactive and ongoing process. The dance makes clear that creation is a movement in which the universe creates itself out of its own destruction. This is why Nataraja is important in this vital understanding.

In different regions, people find different ways to express this insight. Different stories were developed to understand Siva Maha-Kala nature. In South India, in the woods of Maharashtra, lived a group of sages who had strayed from the Way. Siva and Vishnu tried to win the mystics back and restore rule over the area. Vishnu took the form of a beautiful woman, and the anger of the monks increased. Siva Maha-Kala danced to break down the priests' control over the region. The philosophers then created a tiger out of fire to pounce and kill Siva Maha-Kala. Siva Maha-Kala very gently removed the pelt of the tiger and covered himself with the fur of the tiger as if it were a robe. Then a venomous serpent was formed. Siva placed the snake around his neck, which became a most beautiful garland. The heretics then shaped together a giant who looked like an overgrown and deformed dwarf. Siva Maha-Kala broke this monster's back, returning substance to the earth. With song and dance, malevolence was overcome, and everything foul was recycled to create beauty.

Nataraja the dancer produces ecstasy, through which the divine embraces human life. Through the dance, life embraces the four directions. Siva Maha-Kala holds the hourglass drum, which is creation. The drum becomes the pulse of the universe. Sound is the first element created by the universe. From the sound and songs of the universe came the Sanskrit language—the second element and the carrier of wisdom.

Siva Maha-Kala then holds up the tongue of flames that is the next element. Fire is the destroyer. It is the element of destruction, annihilation, and extinction that generates the raw materials for creation to begin again. From this, Abahaya, or protection, is born. Protection is needed for life. Through this dance, Siva Maha-Kala gives birth to the son he sired. Ganesha, the son, removes obstacles to enlightenment, leading to the escape from birth and death.

Original beginnings and inspired strength are possible when slothfulness, apathy, and preoccupation with self are overcome. The soul of the universe rests within the spirit of each individual. Through wisdom, the understanding of this relationship can be appreciated.

Eternity and Time embrace each other. The mountain streams feed the oceans of the world. Siva is both Kala (fleeting time) and Maha-Kala (the Great Time or eternity). Mahayugas, or Great Eons, are but flashes of time. Eternity and Time stand in continual unity, conflict, disintegration, and reunity at every point from the eternal past to the eternal future. Time is the tension between destruction and reproduction.

Buddhism and Maha-Kala

With the rise of Buddhism, Maha-Kala became the realization of the eternity of ever-changing time. Ngawang Drakpa founded the Dhe-Tsang monastery. While traveling in the region of Eastern Tibet, a large crow flew down to the monk and pilfered his scarf. Days later and some distance away, the monk discovered his scarf draped over a juniper tree. This became the spot the monastery was built. To this day in Tibet, Maha-Kala means the "great black one."

The local Bonpo (the indigenous animistic masters) feared the coming of Buddhism. They used magic to prevent the building of the Buddhist monastery. What the Buddhists built during the day would collapse at night. When the crow, Maha-Kala, saw this, he carried a correspondence between Ngawang Drakpa in Dhe-Tsang and the Most Holy Master Tsongkhapa in Lhasa. From this communiqué, the solitary hero Bhairava Sadhana was gathered. This enhanced and intensified the decisive factors of Buddhism. Due to this improved Buddhism, the Bonpo monks became Buddhists.

With the construction of the monastery, it was agreed upon that there was a need for a guarding statue to protect the abbey. That very day, three black men from India showed up and offered their services. These sculptors were contracted to complete the sculpture. When work began on the figure, there was only one black man left. When the icon was only half-completed, a rite was planned and implemented to celebrate the holiness of the site. Tibetan dancers were asked to perform a dance of rejoicing for the ceremony that celebrated the founding of Buddhism in this region of Tibet. With dancing in progress, the black Indian began to dance. No human ever saw a dance more wild or beautiful. Everyone stopped what she or he was doing to watch the untamed magnificence. At the height of the performance, the sculptor disappeared and the image of Maha-Kala was completed. The same mysterious event occurred at the same time at other sites in which two other icons were constructed in exactly the same way. This was the work of none other than Maha-Kala, protector of the holy site and guardian to the Great Time.

Concluding Remarks

In the tradition of India, Maha-Kala represents time, eternity, destruction, and creation. This Great Time leads us to realize that our lives are transitory flashes in the eternal ocean of change. Because of this, our ignorance creates wisdom, pride becomes humility, desire leads to detachment, jealousy gives support to secure accomplishments, and anger gives way to inner peace. Eternity is forever and changes constantly, being destroyed and reborn. The universe also returns to its beginnings and starts over. What happens to every individual happens to the universe.

Malthus, Thomas Robert (1766–1834)

Thomas Robert Malthus was an English political economist of the classical school and a representative of utilitarianism as well as of early demographic science. He is best known for his *Essay on the Principle of Population* (1798), in which he assesses the problems of the growth of the human population in respect to their supply of food and other vital products. Malthus is considered an economic pessimist, an economist of crisis whose theories were of high impact despite their being partially erroneous.

Life and Writings

Thomas R. Malthus was born on February 13, 1766, in Surrey, southern England, as the sixth child of a prosperous family. His father, Daniel Malthus, is said to have known the philosophers David Hume, James Mill, and Jean-Jacques Rousseau personally. Little Thomas was educated by his father and private tutors; starting in 1784, Malthus attended Cambridge University's Jesus College, where he studied mathematics, classical languages, and literature. He obtained a master's degree in 1791 and became a fellow of Jesus College only two years later. In 1797 Malthus was ordained in the Anglican Church and decided to officiate as country clericalist in his home county.

In 1804, however, Malthus resigned from the priesthood to marry Harriet Eckersall, with whom he had three children. Soon after, in 1805, he became the first professor of political economy at the college of the East India Company at Haileybury, Hertfordshire. Already in 1798, *An Essay on the Principle of Population, as it Affects the Future Improvement of Society, With Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers* had been published anonymously. In this, Malthus's main work, which he revised continually until his death, he showed his deep economic and social pessimism, as he was convinced that any increase in productivity and wealth would inevitably be outrun by the evoked growth in the population's number. Consequently, he doubted the benefit of a high birth rate for an economy.

Around 1810 Malthus met one of the most important economists of the time, David Ricardo; an active correspondence and a close friendship developed. In 1819 Malthus obtained fellowship in the Royal Society; moreover he became a member of the Political Economy Club, and in 1834, he was one of the founders of the Statistical Society of London.

In his *Principles of Political Economy Considered With a View to Their Practical Application* (1820) Malthus wrote about the motivating parameters of individual economic decisions as individually rational cost/benefit considerations.

Population Theory

Following David Hume's empirically scientific attempt, Malthus generated his insights with respect to the constitution and the prospect of the society in a completely nonidealistic way, based solely on direct observation. He thereby formed one contradiction of significance to the French Revolution's idealists' and in parts even anarchists' (e.g., Rousseau, William Godwin, and M.-J.-A.-N. de Caritat marquis de Condorcet) theoretic idea of a perfect society.

Malthus did not believe in any kind of utopia. He instead came to the conviction that a steady state of a society's economic prosperity would be utterly impossible due to an inevitably geometrical growth of population combined with at best an arithmetical growth of production of food. In consequence, at any time, the population will be too numerous to live in comfort. War, diseases, and famine are considered natural regulators and necessary to constrain the excessive growth of population and following misery. This bad fate Malthus deemed divine destiny to keep morality and to evade profane idleness. However, later in his life Malthus came to regard self-imposed moral restraint as an alternative check on population-food equilibrium.

Malthus sometimes is criticized for his unfounded usage of statistical methods and subsequent generation of his arguments. On the basis of a sophisticated empiricism, Malthus unfortunately built somehow arbitrarily theoretical constructs of ideas.

Impact

So-called Malthusianism had a sudden and deep impact, especially on English social policy. Malthus thereby vigorously turned the balance against public generosity toward the poor. On the other hand, in stating public investments as a means to resolve economic slumps by stimulating the aggregate demand in his *Principles of Political Economy,* Malthus preceded or at least influenced John Maynard Keynes.

For decades, Malthus's economic doctrine was crucial to the economic and especially welfare-related politics of several European nations. Because of his influence on Ricardo and Keynes, for example, Malthus's thought remains, to some extent, still vivid today.

In evolutionary theory Malthus left his mark as well; Charles Darwin admired him all his life and followed Malthus's thoughts about the struggle of existence and the implication of the fitness of a species' individual representatives for the evolution of the species.

Despite their popularity, wider parts of Malthus's thoughts proved false. As one of numerous examples, he did not anticipate the technological advances leading to the agricultural revolution, which resulted in discharging growing parts of the population from the necessity of agricultural work, thereby paving the way for industrialization. Industrialization in turn finally led to a considerable increase in prosperity.

Mann, Thomas (1875–1955)

Thomas Mann was a highly regarded German novelist and social critic of the 20th century. He won the Nobel Prize for literature in 1929, and his works were considered classics by the end of his life. His novels and essays combined philosophy, psychology, and political insights with his literary craft. His themes often centered on dualism: the coexisting physical and spiritual human natures, the life of action and the life of thought.

Mann's writings detail the complexity of reality and time. *The Magic Mountain,* his novel published in 1924, most clearly explores the inner time-consciousness of the main character, Hans Castorp, as he seeks knowledge and adjustment to life in a tuberculosis sanatorium. This novel is full of references to understanding time. Mann insists that time cannot be narrated and is not linear. Hans remarks about time being a turning point in a circle. The daily routines and seasons circle around the characters' lives.

Thomas Mann was born Paul Thomas Mann into a prosperous middle-class family in Lübeck, Germany, on June 6, 1875. He was baptized as a Lutheran. He was one of five children of a prominent merchant and city councilman. When his father died, the family moved to Munich, where he received his early education. He began the daily habit of writing in his personal diary when he was a schoolboy in the 1890s. In 1905, he married Katia Pringsheim, an educated woman and the only daughter of a professor in Munich. She devoted herself to him, his career, and their six children. He traveled on the lecture circuit and vacationed around Europe. They had a life of culture, order, and comfort. He had many famous acquaintances in the fields of literature, music, psychology, and politics of the time.

In 1933, while Mann and his wife were vacationing in Switzerland, they were advised not to return to the political turmoil of Germany. Adolf Hitler's actions forced Mann into a reluctant exile. Mann was very concerned about getting his private diaries back. On July 7, 1935, Mann received Harvard University's honorary doctor of letters degree with Albert Einstein. In 1938, Mann and most of his family settled in the United States, where he continued his writings in the German language. His children grew up to succeed in a variety of literary and scholarly endeavors. In 1944, he became a U.S. citizen. Mann moved back to Switzerland and died there on August 12, 1952.

Major Novels and Essays

After writing several essays and journal articles, Mann published his first novel, *Buddenbrooks,* in 1901. This novel thoroughly detailed the story of three generations of a family as they declined physically but grew to include several failed artists. The values and attitudes of the middle class were in conflict with those of the artists. These internal conflicts of opposing forces leading to change are associated with the philosophy of dialectics. Mann read the classics, and his writings reflect his thinking about the nature of Western middle-class culture as well as his version of his own family.

His short novel *Death in Venice,* published in 1912, also is considered a mirror of his own life and his psychological issues. This novel details a writer's moral conflict and collapse through a humiliating, uncontrollable, and unfulfilled passion for a young boy.

During the period from 1914 to 1918, Thomas Mann supported Germany's slide in World War I. He wrote a lengthy essay published in 1918 as *Reflections of a Non-Political Man.* This was part of a disagreement with his older brother, Heinrich Mann, who was also a published author but who was very opposed to the military buildup in Germany. At this point, Thomas Mann praised Nietzsche for supporting the acceptance of ambiguity as a great personal strength. His essay claimed the romantic view that art would not surrender to the system but could remain isolated from politics. Later he realized that this position was political itself, and he finally reconciled with Heinrich in California in 1942.

The publishing of *The Magic Mountain* in 1924 marked the end of 12 years of work. Just as he had come to believe that there is no turning point in politics, this work incorporated the notion of time's circular nature in both the novel's form and its content. The reference to time not being linear seems to refer to Hegel's idea about bad infinity being linear but real infinity being circular and dialectical. The protagonist Hans Castorp notes that the longest day of the year, June 21st, is called the first day of summer, yet the days start getting shorter at that point, so it truly is the beginning of winter. Joy and melancholy can exist at the same time in a dualistic philosophy.

Mann used techniques of the composer Richard Wagner to tell this story: multiple themes with variations and the exploration of the characters' emotional lives. This novel is based on the setting of the Davos Sanatorium, where his wife spent 6 months in 1912 for a lung condition. *The Magic Mountain* is an allegory of Western civilization's sickness as well as a sympathetic telling of the story of individuals dealing with personal sickness, real or imagined. Man is the master of contradictions, and the human goal is not to decide but to reach harmony with the human condition.

Through the years Mann wrote essays on Freud, Goethe, Nietzsche, Tolstoy, and Wagner. These essays detail his intellectual struggles, which shaped his fiction writing. He wanted to understand people completely and took great interest in understanding himself and his world, as is minutely detailed in his diaries.

In 1943, Mann published a four-novel series on the biblical Joseph, *Joseph and His Brothers*. The project took him 10 years to complete. This epic begins in the timeless tribal existence of the desert and moves into the historical timeline of Egyptian civilization. Mann wanted to restore a belief in the power of humane reason. These novels show the individual as a reflection of his epoch as well as of his personal story.

Doctor Faustus, published in 1947, tells the tale of a great German composer who bargains with the devil and rejects love and moral responsibility in favor of artistic creativity. Mann connects the 12-tone musical system to totalitarianism. He writes that a chord has not one key but is all about relationships. This became a novel about commitment and the failure of accepting ambiguity. At the end of his career, he finally chastised the dialectic and recognized the importance of fighting evil. He aided the Allies through his writing and saw Franklin D. Roosevelt as saving the world. He chose to leave the United States when the anticommunists and Senator Eugene McCarthy held power and influence.

Maritain, Jacques (1882–1973)

Jacques Maritain, French Catholic philosopher, composed numerous influential works on topics including epistemology, metaphysics, moral philosophy, sociopolitical philosophy, philosophy of art, and mysticism. In Maritain's metaphysical philosophy he discussed the experience of the progression of time by finite beings in contrast to the divine, eternal perspective of time. In the latter, all moments of time are simultaneously known in a single instant, which has neither beginning nor end. Maritain also held that the human soul, which he associated primarily with intellectual activity, was eternal, existing always in the thoughts of the creator. Maritain's Christian-humanist perspective has been called Thomist, owing to Maritain's great affinity with the perspectives of 13th century philosopher and theologian Thomas Aquinas.

Born in Paris in 1882 and baptized into the French Reformed Church, Maritain studied philosophy and science from 1901 to 1906 at the Sorbonne, where he met Raïssa Oumansoff, a Jewish Russian student whom he would marry in 1904. Jacques and Raïssa Maritain became disillusioned with the rationalist scientism at the Sorbonne, and they resolved together to end their lives in suicide if they could not find a satisfactory understanding of truth. In their subsequent quest the Maritains were influenced first by the metaphysical perspectives of Henri Bergson and then by the writings of Léon Bloy, which led them to convert to Roman Catholicism in 1906.

Maritain began to study Thomas Aquinas's immense work, *Summa Theologiae,* in 1910. Aquinas's perspective appealed to both the philosopher and the Christian in Maritain, and its impact on him was acute and enduring. Maritain soon began publishing, and he lectured in philosophy at the Institut Catholique de Paris from 1913 to 1933 and at the Pontifical Institute of Medieval Studies in Toronto from 1933 to 1945. During these years he wrote without ceasing, becoming the dominant philosophical voice for Catholics in France and the United States. After World War II Maritain served as the French ambassador to the Vatican from 1945 to 1948, personally befriended Pope Paul VI, and taught philosophy at Princeton until retiring in 1956. After Raïssa's death in 1960, Maritain joined a Dominican order, The Little Brothers of Jesus, and lived with them in Toulouse as a hermit until his death in 1973.

In *Existence and the Existent,* Maritain discussed the relationship between time—the experience of finite beings—and eternity—the divine perspective of all existence. From the perspective of divine eternity, all moments of time—past, present, and future—are present and tangible in a single instant, Maritain reasoned. This eternal divine perspective does not imply absolute determinism, according to Maritain, but included acknowledgment of the free choices given to created beings, which rightly operate within the measurable succession of time. Along similar lines, Maritain viewed the human soul or intellect as eternal and timeless, presupposing that the intellectual activity observable in human beings must always have been and must always be existing, even before its creation in the thoughts of the creator.

In reflections and observations about history, Maritain—though highly modern in many ways—despaired of much of the course of the modern world. Maritain saw in history a pattern of contrasting progresses. He observed that while modern civilization had clearly achieved many advances in scientific knowledge and humanitarian causes, these gains were mirrored by moral and spiritual depravity, political totalitarianism, and wars with unprecedented cost of human life. The answer for Maritain lay in neither capitalism nor communism but in a renewed Christendom characterized by justice, truth, love, and tolerance. Seen in many ways as a liberalizing influence in Catholicism, in 1967 he shocked many by writing very critically of Vatican II in one of his last works, *The Peasant of Garonne.*

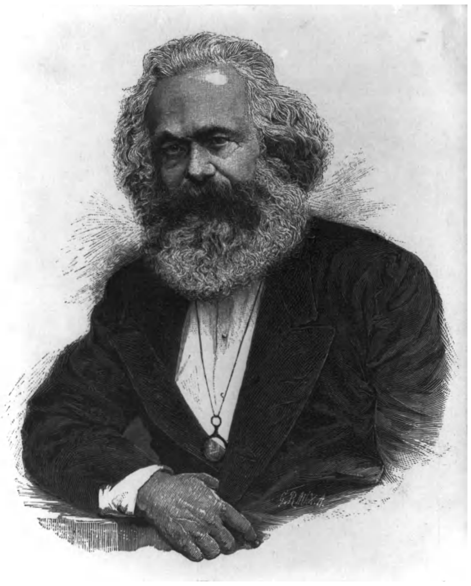
Marx, Karl (1818–1883)

Karl Marx is often named as one of the two greatest intellectual innovators of the 19th century, the other being Charles Darwin. He helped to redefine the fields of sociology, history, economics, and anthropology. Much of what followed in these disciplines is a response to the theories he outlined in his writings. Known as the father of Marxism, a revolutionary socialist movement worldwide, he also strongly influenced and in part defined such topics as social stratification, historical sociology, materialist anthropology, cultural ecology, social history, and social economics, just to name a few areas. For example, sociologists since Marx have tried to disprove, defend, or reform his theories. Few can ignore the writings of either Marx or his followers.

Karl Marx was born in the German Rhineland city of Trier on May 5, 1818. Both his mother and father were Jewish by birth. However his father, who was well read in the humanist writings of the Enlightenment, converted to the Lutheran faith to secure employment opportunities at a time when many occupations were closed to Jews. Marx's mother and the rest of his family converted later. Having been born into a Jewish family and raised as a Protestant in a Catholic city helped mold the character of young Karl.

At age 17, Marx enrolled in law school at the University of Bonn. At Bonn he became engaged to Jenny Von Westphalen, the daughter of a baron who was also a professor at the Friedrich-Wilhelms University in Berlin. The next year, Marx transferred to the University of Berlin. There he became interested in philosophy. He associated with the Young Hegelian movement, which was a radical humanist movement. Because a university career was closed to all Young Hegelians, Marx took up journalism as editor of the radical journal *Rheinische Zeitung*. This would eventually result in Marx's exile to Paris.

In Paris, Marx made contact with the French socialists. As a result of pressure brought to bear by the Prussian government, who feared the anti-Prussian underground in France, Marx was labeled a radical and an undesirable foreigner and was forced by the authorities to leave Paris; he moved to Brussels, where he lived for three years. There Marx dedicated his time to an intensive study of history and expanded the materialist conception of history. He developed what later would become known as historical materialism. In 1848, Marx moved back to Paris in support of the revolutions in France and Germany. In 1849, he moved to Britain, where he died in 1883. Marx developed his methodology of historical materialism in the early years, and it served as a model for his later work in political economy. It is important to analyze the evolution of his life from the days when he was influenced by the Young Hegelians until he wrote *German Ideology* in 1847 as he moved from philosophy to historical sociology.



Karl Marx, the father of modern communism. Marx believed that the downfall of capitalism by revolution and its replacement with a society based on socialism was inevitable.

Marx the Scholar

According to Irving Zetlin, Karl Marx is credited with establishing sociology as a discipline. Since then, sociology has been defined by a debate with the ghost of Marx. Karl Marx was a true heir of the Enlightenment. Marx's sociology was historical, materialist, and dialectical, and it was part of a social, political, and economic revolution. In his early years, Marx was interested in philosophy, encouraged by his association with the Young Hegelians. These philosophers wore their radical atheism as a public badge of honor. Particularly influential in the life of young Marx was Ludwig Feuerbach. Feuerbach taught that God is a human creation in which human characteristics, requests, requirements, and promise are projected onto an entity that is creative fiction. We then worship that entity as if it were real. He believed that ideas actually come to pass from the lives of real people. Therefore, only when people come to realize this can they end their alienation and restore their species-being. This is our shared common humanity. From this, Marx arrived at the idea that we would need to look at how real people live in their environments in order to study properly the content of their cultural ideas, ideology, and religion. Political beliefs, values, ways of life, and religious convictions all develop and change within human communities. These communities are embedded in an ever-changing environment. The environment is rooted in a constantly evolving set of conditions.

In the following sections, the principles Karl Marx espoused are briefly outlined.

Early Marx

Following is a summary of the young Karl Marx's views on democracy, power, the state, religion, bureaucracy, and law. According to Marx, democracy makes the assumption that all people are equal, even if they are not. The nature of any state is the specific historical circumstances that reflect particular social relations. The state is the design of unequal amounts of power that competing groups use to control the administrative system of political institutions.

Power, within the politics of a state society, often appears to operate independently of individuals within that society. In point of fact, groups compete with vastly different amounts of political power. Power cannot exist as a force independent of individuals within these competing groups. Economic classes and social groups compete over control of resources that are necessary for wealth and power. The state appears to operate externally to and autonomous of these struggles. This is a hallucination. The state is constantly changing, reflecting changes in these power struggles. While the political appears to be the cause of these changes, it is more like the effect. The state as a neutral arbiter of these conflicts is reflective of power, wealth, and class interests. Not all classes, families, or individuals are equal in their influence on the state. Being a neutral arbiter is an illusion.

Social interaction between real people, like families and the surrounding community, can be observed empirically. This includes how people provide for their material needs collectively in that community through working together. This is called interaction in civil society. Civil society is an abstraction that reflects authentic social relationships. Civil society is the private satisfaction of personal desires in a social setting. The state reflects the public expression of power; it is also an abstraction that illustrates genuine social relationships. The state is the public manifestation of the private yearnings expressed in civil society; it is made up of real individuals interacting and competing for political power. These human beings relate mutually to nature and each other through work, forming groups to cooperate in meeting their real physical and social needs. The state is the public expression of this, and civil society is the private expression.

Because ideology is used to justify one group's control over economic resources necessary for political power, it is usually declared that the dominant group represents all of society, including the powerless.

The state, according to Marx, cannot be separated from real individuals. There are real people doing what they must to survive. In order to live, people need access to economic resources. Each group competes for power with unequal political resources. Sovereignty is understood as the abstract reflection of who has more real power. This abstraction is often confused by the fact that appearances mask reality. Sovereignty appears as that which gives people power. Individuals define their citizenship within this struggle for sovereignty. However, with control over basic resources, political freedom masks real oppression and exploitation.

Humans are human only in a social context. The "social" is made up of definite individuals. The individual is a social product. The state and civil society are interconnected abstractions, and the separation of the two is an intellectual tool that makes the science of society possible. The government (state) only appears as outside of and above individuals of civil society. The monarch is a real person who abstractly stands for the state. The state is an abstraction of power used to coerce the people. The monarch uses real power supported by other individuals, the military and police, to enforce his will. Others who work for the monarch use implements of coercion to force people to obey the will of the monarch. This threat of violence is reinforced by ideology, doctrine, and religion. The monarch is the personification of the sovereignty of power. People are excluded from the use of power. The monarch represents the unity of the people, a people without power.

Sovereignty of the people is a concept that stands opposed to the sovereignty of the monarch. The monarch speaks for God and not the people. In a republic or democracy, the government is the imagination of an abstraction called the people.

Instead of sovereignty defining citizenship, it is the belief of the citizen that gives sovereignty its perceived reality. Each type of government reflects real power relationships between groups of individuals. Thus, each government defines sovereignty to meet the interests of the more powerful group. The military, the courts, the church, and the media define what most people believe to be real about sovereignty. Political consciousness and political culture are learned in institutions that are largely controlled by the power elite. These learned explanations justify and hide real power in society. In order to operate more smoothly, the established power relations are often falsely represented as being in everyone's best interest. Alternative views are learned, in opposition to the established political culture. Each form of government is part of a cultural completeness, which everyone is taught to see as true. Imperial democracy is no contradiction. These abstractions reflect the interests of those who control the political resources of the state. Political constitutions operate on faith. A republican body of laws reflects the development and evolution of commerce and private property. Government based on a constitution is a bourgeois artifact. During the Middle Ages, property, economy, and society were embedded in the political structure. In capitalist society, the separation of the economic from the political is possible because of political action and reflects the interests of the economically powerful.

Religion in a monarchy is the foundation of the political constitution. A republic or democracy uses the private lives of its citizens as its justification. Private property and commerce are the material groundwork for the republic. In a monarchy, private property and commerce are political gifts of the sovereignty.

Bureaucracy is the practical structure of the state. It is the social relationship in which the abstract state becomes real. There are hierarchies of power that used specialized knowledge as their justification. The imaginary state functions through a real bureaucracy.

Bureaucracies specialize in carrying out the mundane details of the state. Formal goals are translated into action, coming into conflict with real goals. Specialization creates a hierarchy of knowledge. The upper echelons of the hierarchy are in charge. The lower levels carry out the mundane details. The bureaucracy operates outside of government and is a real part of the state. In carrying out the law, the law is changed. This is a daily process, continually causing the constitution to become obsolete; therefore, it must be updated when the discrepancy becomes too great.

The law exists only in people's imagination. The law becomes real because people, including people who enforce the law, believe it to be real and behave accordingly. Laws must first be interpreted, and the interpretation is constantly subject to change. When people in power replace old laws with new ones, change is amenable. Individuals must inevitably give up their interpretations and accept the official one.

The private realm in a republic is established through economic inequality. In public, the political lives of the citizens appear to be equal. Inequality requires the illusion of equality to make it seem acceptable. Freedom is established through a lack of freedom. This means that persons are free to work for anyone who will hire them. If they do not work for someone and accept that individual's authority, they die. The republic has freed them from the feudal lord only to enslave them to the owners of business.

Marx: Jews in a Christian State

In Marx's view, the Christian state oppresses everyone. The issue of emancipation of the Jew requires the emancipation of the Christian at the same time. The Jew is a Jew because he says no to Christ. The Christian cannot free the Jew and still be a Christian. The Christian state, because it represents Christianity on some level, must exclude Jews from being treated as fully equal. Religious constraints undermine political emancipation. The official recognition of one established faith as being more important than others oppresses everyone. People must insist on the complete separation of church and state. The legal abolition of any established religious privilege is a prerequisite for popular sovereignty or democracy. Religion must remain a private decision. If one chooses to have no religion, that decision must be protected. Not any one religion should be necessary for political power.

Freedom from religion and freedom of religion are two sides of the same struggle. The ultimate religious freedom is when the state recognizes no religion as superseding any other. Only when religion is recognized as a private decision, and only when one is free not to believe in any kind of higher power, is there freedom of religion for all.

The state must become secular. Humanism is a belief in all religion as superstition. Humanists believe than humans can be ethically decent and richly fulfilled without a higher power. Because secular humanists do not believe in a god, their religious freedom is the test case. If they are free to not believe, all others are free to worship in their own way. Religion becomes a private decision and is kept out of the public discourse over policy. In a secular state, people become the universal abstraction, replacing God as the political explanation of the state. The secular state then unites the believer and nonbeliever. The public realm protects the private realm, allowing for a great deal of diversity in society.

There cannot be much freedom of diversity in a Christian state. Religion limits choices. The state remains incomplete, because it continues to exist only by being attached to religion. Faith supplements coercion. In a democracy, the paramount hypothetical excuse for the state is "the people" and not "God." It is necessary for a democratic state to stay away from any religious commitment to God, or the philosophy of democracy is compromised. Religious accountability must remain independent of the commonly shared political culture of a nation. The foundation of democracy is the secular state. A Christian state, an Islamic state, or a Jewish state cannot be democratic.

Human rights struggles are historically a contest against tradition. Traditional religions are the heritage of the chosen. Even if a Christian state guarantees religious freedom, it still favors Christians over Jews. The confinement of privilege divides. Equal rights to diverse opinions in a matter of faith can exist only in a secular community. The state protects the religious rights of all by restraining the religious power of the favored group.

Liberal democracy requires egoism, individualism, private property, and freedom of expression in matters of faith. The liberal will claim that the rights of one individual are limited only when they threaten to injure the rights of someone else. This assumes equality, yet because of private property the society is founded upon enormous inequalities. Freedom of egoistic individualism was the result of political revolution. The civil society of religion was replaced by a secular egoistic civil society.

When the individual Christian is no longer Christian, individualism replaces the Christian community. The commitment to "other" as the basis of the Christian community is replaced by the selfish crusade of greed. The new state protects the individual citizen who is atomized in his greedy quest for power and material things.

Beyond Capitalism

According to Marx, people create their religious beliefs from their own imaginations. Religious beliefs reflect the real world and the lives of real people. Faith is the hope of the powerless. The only real power that can overturn the attraction of faith is the power of people who have real democratic control over their lives. The lack of collective control over the political power and the economy of a society make religion a necessity to help people get through each day. Happiness in this life requires people to be the authors of their lives and not victims. Political struggles need to deal with social and economic conditions of life, not merely to provide philosophical debates over religious issues.

Political action and philosophy cannot be disconnected without making both negligible in changing the lives of the poor. People cannot have genuine political power without first having collective control of their actual lives. This means they must have cooperative control over the economy. This can happen through joint action of a social movement. The capitalist came to power by way of a liberal political revolution. Liberal philosophy and capitalism are tied together and cannot be rent asunder. Private property and individualism are represented in each person's self-interest. Only when it is questioned whether some groups benefit more than other groups does liberal philosophy begin to unravel. The capitalist now replaces the feudal aristocrat as the major oppressor of the direct producers, the poor.

The liberator soon becomes the new oppressor. The capitalist class fights for liberty, human rights, and private property against the ancient feudal order. When capitalists gain power, human rights cannot threaten their private property. The working class must be kept in tow. The poverty of the worker becomes a necessary condition for the wealth of the capitalist. Workers need their own revolution to go beyond the liberal society of capitalism.

Alienation

Workers, wrote Marx, create wealth; the wealth belongs to the capitalist. The capitalist becomes rich and powerful because of the wealth created by the workers. The workers become weak and poor as a result of their labor. This is because the labor of a worker is sold to the capitalist like any other commodity, and the capitalist will try to buy it as cheaply as possible. By selling the products of labor, the capitalist gains his wealth. This wealth is the source of the capitalist's power over the worker. Workers sell the source of their own slavery. The products made by workers become their chains of bondage.

Nature, which is necessary for life, must first be changed through labor into the means by which we are able to live. Humans, being a part of nature, are free only as a part of nature. Because the resources of production belong to the capitalist, nature becomes an unavoidable condition for the enslavement of the worker. They can live only if they get jobs. Their physical survival is possible only if they can find work.

The true nature of work is art. Work is the creative relationship between the worker and the rest of nature. Only through labor can we develop our full creative potential as humans. Yet the planning and design of labor is taken away from the worker. For the capitalist who owns the resource, the final product, the labor power, and the labor process, work becomes a source that cripples the worker. This turns workers into an adjunct to a machine. They can live only at the pleasure of this stranger who has plundered their humanity. Workers, once a vital part of nature, are now foreigners. Nature, their human essence and their birth, is now an unfriendly centaur prepared to devour their lives. The artistic celebration of life through labor is forever shattered. Our kinship with nature is eternally vanquished.

Workers stand in open competition with their coworkers. Their community has been plundered from them. Private property separates workers not only from nature but also from their own community. Greed and envy, as well as lewdness and ill will, become the glue that holds together a society founded upon accumulated wealth, individualism, and private property. The wealthy are always in awe of the wealthier but are also spiteful and afraid of the very rich. Wealth requires the cunning to live off the income looted from the workers. Until everyone becomes a worker and all wealth is held in common, the rich can only survive by stealing wealth from the poor.

The abandonment of private property is only the first step in returning the wealth to the poor who originally created it. We can democratically control our own society only after everyone becomes a public employee. Democracy grows only by empowering everyone through democratic control over the process of production. This process reintroduces the aesthetic and harmonious connection between the workers and nature. The alienation of all workers from nature, from the products they make, and from the community in which they live amidst the very process of creation will come to an end. Only then will the estrangement of one's work that has been plundered be returned. Democracy, socialism, and communism are our rediscovery of nature. Humans are not only a part of nature; they are human only in a natural and social setting.

It is through labor that this unity between the individual, the community, and nature becomes real. Humans are as much a product of social labor as they are a part of nature. We not only produce, we create ourselves. We write our own history through our social interactions in a natural and social setting.

Logic and philosophy become separated from the practical. Intellectual work becomes separated from physical work. This is a counterfeit way to live. Nature becomes alienated from nature, and our lives from reality. Living nature becomes a lifeless fact. Workers can regain their souls only if they are able to bring together abstract thought with the natural setting through their joint activities with other workers.

Equality is achieved through the celebration of nature and our common humanity. This is communism. Communism occurs where nature and humanity meet through democracy. Socialism is the path to communism. The mind and the body are reunited. Political democracy is transcended by economic democracy. Alienation is replaced by a communal relationship with nature. Thought, action, and creation are brought together as people are reintroduced to nature. We, as humans, live life as a ceremony to be fully indulged and as a burden to be endured. Work becomes entertainment and not drudgery.

Labor can become fulfilling only when private property has been eliminated. When owners possess nature, those who do not own anything become objects for sale. The life of workers becomes sold to the highest bidder; where slaves are abundant, their price is low. Capitalism cannot be reformed, and it can never be democratic. Workers are not human but objects of trade. Their lives are those of slavery and alienation. The ethics of communism require that all people should be the composers of their destinies and not their blood offering. People must be reunited with themselves.

Marx's Method

The real study of history, in Marx's view, begins with the material formulation of real people living their everyday lives, with people's relationship to nature. Through these relationships, humans produce their own means of subsistence. Each generation inherits and reproduces this means of subsistence and then changes it to fit their changing needs. This happens in the context of a historically and culturally specific setting and shapes individual human nature. Production determines how people are organized and interact.

Production molds all other social relations. This includes the relations of one nation to another as well as the internal social structure of a single nation. With every new change in the forces of production, there exists a corresponding change in the relations of production. These changes lead to changes in the division of labor. With changes in the division of labor, there are changes in the property relations of the nation. Ultimately, this means ideology changes as well.

The earliest division of labor is between the town and country. Industrial and commercial interests are separated from agriculture. With these changes in the division of labor, there are changes in property relations. When private property restricts access, the resources of subsistence become constrained. Each type of stratified society is founded upon this unequal access to needed resources. Each society has its own type of ownership and its own type of property relations. Historically, specific relations then develop between groups of people.

The first type of property is tribal or communal. This undeveloped stage of production has simple technology. The social structure is based upon the family and the extension of family called kinship. This evolves into ancient communal or state ownership. Private property develops but remains subordinate to the communal property of the state. With the development of an economic surplus, the town or administrative center stands opposed to the countryside that supports its life.

Feudal ownership begins with estate ownership. Peasant serfs are the economic foundation. Property is organized through hierarchical land ownership. Nobles are an armed body of retainers. In the city, the guilds of master, journeyman, and apprentice copy the feudal relations of the country. Property ownership changes to meet the changes in production relations; this causes changes of the status of the serfs and in relations between the town and the rural aristocracy. This occurs because social relations continuously change. The ideas of the age are the direct result of the real material life of the people. People produce ideas through their productive lives.

The first historical act is production to satisfy material life. Following the first historical act is the production of new needs that are the practical result of satisfying the needs of material life. People reproduce themselves, their families, and their culture daily. These acts of production and reproduction are exhibited by the historical past of a people; but this very activity also changes both the people and their culture. Old needs are changed and new needs are created. With expanding needs, production of life is both social and natural. Humans are both the animal creations of nature and the social creations of society. Each society creates its own social organization based upon its own historical mode of production. The nature of society is based upon the mode of production and consciousness. People's relation to nature molds their relation to each other. People's relation to one another affects their relation to nature. Production, human needs, population pressure, and change will follow.

The division of labor begins within the family. After that, within the rest of society, the division of labor continues to evolve. It subdivides between mental and physical labor. With this division of labor, an unequal distribution of property (both quantitative and qualitative) and its resources occurs. This leads to the development of private property. Private property results from the activity of the property-less and grows as a result of that activity. Because of the development of the division of labor, there is a concurrent development of the contradiction between the individual and the community.

With these divisions between ownership and work, mental and physical labor, and the community interests and particular deeds of labor, property becomes an alien force. The alienation of the worker occurs within society. Tools, resources, and human activities appear to control people rather than being controlled by the producing people. Through increasing specialization, labor is imposed upon the individual as a source of exploitation. The job also appears to own the individual. What we produce becomes an objective power over us. These illusions take on a reality that frustrates our best-laid plans.

During the evolution and development of alienation, the state develops as a community divorced from the realities of the individual. The state becomes a community unto itself. It is important to remember that the struggles within the state are class struggles. These struggles are class wars for mastery of the political powers of the state, whether peaceful or violent. Each class tries to conquer power in order to best represent the interests of that class. Any cooperation that exists is determined by the division of labor of that particular mode of production and by the class that controls the state. This cooperation is not for the benefit of all. The goal of cooperation is to benefit property owners who control the power of the state. Property relations, cooperation, and the state all change as a result of these class struggles. Society changes and the culture itself changes because of events brought about by this class struggle. Any kind of property relation that restricts access to resources causes resistance among the people who have limited or no control over the property that they work with to produce a surplus, which the nonproducers accumulate. Any indigenous class struggle is always an international class struggle. The world market economy exacerbates this struggle, and international struggles are then expressed locally.

Because property ownership restricts people's access to needed resources, direct producers become estranged from themselves. Material and intellectual production, as well as the producers themselves, do not belong to the producers but to the nonproducing minority. Until people are reunited with their creativity, work becomes a painful experience. When people become united with their own creative activity, they then achieve the capability to experience a joy that life holds dear. Cooperation must be transformed from cooperation for the benefit of the few into cooperation for the benefit of all, so that work and joy may be reunited. With the universal development of the productive forces of a market economy, a contradiction between the worldwide interdependent social economy and the private control of that economy for the benefit of the few is established. Only a world revolution can resolve that contradiction.

The universal development of production is a precursor to most people becoming property-less on a global scale. At the same time, world history replaces local history. Civil society is the result of the historical development of a new global system of production. Civil society is then seen as the material relation between people, people and nature, and the forces of production. This civil society exists only because of the rise of the bourgeoisie along with the evolution of the modern state, industrial production, world commerce, and professional bureaucracy.

History can be defined as a succession of economic systems along with changing ideological traditions. History modifies old circumstances by changing activities. The products of consciousness are the products of social life. Ideas reflect material production and its social relations that are historically inherited. Circumstances create people the same way that people make circumstances.

Humans need each other for survival. People cannot be free if they are hungry. Freedom is a historical action and not a state of mind. Freedom, if it is to exist, must have historical and technological foundations. Because the world is altered by the changes in industrial production, it can either increase alienation and exploitation of the direct producers, or it can increase freedom, depending on who controls the means of production. In the end, society changes according to the changing needs of social production.

Human unity with nature exists through industry. Social science must reflect this if it is to understand the deeper underlying connections between specific social actions and global trends. Industry, commerce, production, and exchange establish distribution, which in turn gives birth to ideological possibilities. Along theses lines, socioeconomic classes are determined by the mode of production. Every class society creates its own ideological support. Bourgeois society develops science to meet the needs of its mode of production. This is possible because the ruling ideas of any class society are those of the ruling class. Those who control the material forces of society rule the ideas of that society. Workers are subject to those ideas. The dominant ideologies reflect the dominant material relations.

Division of labor begins with the separation of physical and mental labor. Class antagonism soon develops. The exploited classes become the revolutionary classes. Each new ruling class presents its particular interests as the interests of society as a whole. This means the class making the revolution speaks as the new leader for the entire society. In the beginning, the revolutionary class leads the opposition against the old ruling class. The revolutionary class at this time is connected with the oppression of other exploited classes. Once the new class gains control of the state and the new means of production, opposition to the new class fully develops from yet other exploited classes. The old ruling ideas die with the new ruling class, and their new ideas become the dominant ideology. New opposition develops a new alternative ideology for a new struggle against the current ruling class.

Nature is constantly altered through human labor. This causes nature to become a product of human labor. The separation between town and country develops with the separation of mental and physical labor, and this leads to the development of state society. The class of nonproducers controls the coercive powers of the state and the means of production. When this happens, private property develops out of the surplus created by the producers who now have no property.

In the Middle Ages, the urban rabble controlled no resources; thus they were the most oppressed. The journeymen and apprentices were organized to meet the interests of the guild masters. Peasants remained isolated and weak and were controlled by the lords. Fear of the rabble united the nobles, the masters, the journeymen, and the peasants against this element in the towns.

Separation of production from commerce arrived with trade. Merchants became the new class. Manufacturing grew out of this marriage of merchants and guilds. Merchant capital became movable capital; the guilds became increasingly independent from the merchants. The merchant could then hire workers outside the guilds for manufacturing. With new types of manufacturing, unemployment became common.

With the rise of manufacturing, nation-states increasingly competed with each other. Trade wars became common. Within the nation, the capitalist and the worker related and competed with each other. The big bourgeoisie came to dominate the means of production but not the state. Commerce and navigation expanded rapidly, making the national bourgeoisie international in scope. Navigation and colonial monopolies went together. Protective laws sheltered the older bourgeoisie, making them dependent upon the state. The colonial monopolies controlled the market, and at home the market was administered and protected. Free trade was banned.

Competition came with big manufacturing. Movable property evolved into real private property. Competition separated the bourgeoisie and the workers from their own classes. Through private property, the state became independent of other forces in society. This was done even though the state organized society for the general interests of the bourgeoisie. Through the state, individuals of the ruling class asserted their common interests in spite of internal conflicts among the capitalist class. This was done because the state mediated the larger common interests of the capitalist class. There was a disintegration of natural communities with the evolution of private property, and civil law grew to define private property and natural interests.

Civil law defines property as if it were the general world of the people, not the property owners. The bourgeoisie, as a class, slowly absorbs the other propertied ruling classes. Its mode of production becomes dominant. The proletariat without property develops at the same time as this capitalist class. Industrial, financial, and commercial property becomes the dominant theme that relates to all forms of property. One class has conflicting antagonisms with another class. Class position limits life choices and defines the limitations and potential of every individual. This division of labor creates a reality independent of the will of the parties involved. Freedom can only be established on material grounds in a community in which the division of labor has been outgrown. In the past, economic reality acted independently of the will of the individuals of that society. Class is defined as a community that shares a common interest. Class is a condition of life and lifestyle.

Freedom is possible in resistance to oppression. Communism overturns all earlier forms of relations of production. Control of necessary resources returns to a community of individuals. This struggle is shaped by the material life and the history of a people. The conditions of real activity, which are the preconditions for the movements of a society, become a fetter to further movements of a people at a certain point. The resulting effect is that one type of material activity replaces another.

Historical conflicts grow out of contradictions between coexisting productive forces and between those forces and the rest of a society. The industrial capital of an advanced nation exports those conditions all over the world. Big industry equals social production while it is privately owned. This type of private property is the result of the accumulated labor of others. The division between ownership and labor becomes complete under capitalism. Forces of production do not belong to those who work with the tools of production but rather to the nonproducers. In modern industry, the workers are separated from the tools, their work, the products they make, themselves, and their coworkers. In addition, the state looms over them like an alien power opposed to the workers' class. The ruling class sets forms of distribution in motion that reproduce this inequality. In Marx's view, revolution becomes the only hope of the oppressed and exploited.

Materialism

Philosophical materialism maintains that all things can be understood in terms of matter in motion. The only things that exist are matter and energy. Because of this, there is an association between different varieties of materialism and the scientific method. Many scholars credit Greek philosophers such as Democritus and Epicurus as the intellectual predecessors to philosophical materialism.

During the 17th and 18th centuries, materialism emerged as a philosophical tradition. Pierre Gassendi (1592–1655) raised the question of consciousness as integrated into the physical world and known through the senses. Julien Offray de La Mettrie (1709–1751) and Baron Paul Heinrich Dietrich von Holbach (1723–1789) taught that consciousness is simply the consequence of the biological structure and activity of the brain. Dialectical materialism and physicalism have existed since the 19th century as the modern expression of philosophical materialism. Physicalism is the point of view that any observed study can be articulated as a record of visible physical objects and events.

The main principle of dialectical materialism is that everything consists of matter briskly in motion, and everything is constantly changing, breaking down, and dying, while constantly being renewed and reborn. This is "the struggle of opposites."

Physicalism, or logical positivism, states that most things can be understood through science and mathematics. The pronouncements made by metaphysics, ethics, and religion are pointless, because their proposals cannot be verified by observation and experimentation or by logical deduction.

Three themes relate historical materialism to social action. They are materialism, action, and freedom. Action within nature is central to movement. Freedom through action is central to liberation and sovereignty. By way of action, we continuously alter the orchestration we have with nature. Given this, preexisting but changing boundaries limit freedom. Frontiers we cannot transgress include the physical universe, biology, ecology, social arrangements, technology, populations, organization, social design, and the mode of production. Theory leads to action; from action comes theory, freedom, determinism, and moral choice. This interaction cannot be separated. Natural history, which consists of geology and biology, is in inseparable unity with human history, which includes history, sociology, anthropology, and psychology.

Methodological Materialism

Karl Marx

The German economist Karl Marx (1818–1883) subscribed to the concept that there are real regularities in nature and society that are independent of our consciousness. This reality is in motion, and this motion itself has patterned consistencies that can be observed and understood within our consciousness. This material uniformity changes over time. For Marx, tensions within the very structure of this reality form the basis of this change; this is called dialectics. These changes accumulate until the structure itself is something other than the original organization. Finally, a new entity is formed with its own tensions or contradictions.

Human interaction in a natural setting is a given, because people are, at their core, a part of nature. It is because of this interaction that people are able to live. Through cooperation and labor, people produce what they need to survive. People live both in a community and in a natural environment. Any study of history cannot separate people from either the social or the natural environment.

According to Marx, the interaction between a social organization, called *relations of production,* and the use of technology within an environment, called *forces of production,* can be used to understand many particulars about the total culture. The evolution from band-level society to tribal-level society, tribal to chiefdom, and chiefdom to state-level society, has to take into consideration changes in the organization of labor, including the growing division of labor and ultimately changes in the technology people use.

With changes in the organization of labor, there are corresponding changes in the relationship to property. With increasing complexity of technology and social organization, societies move through these diverse variations to a more restrictive control over property; eventually, in a state society, restrictions develop around access to property based upon membership in economic classes.

A social system is a dynamic interaction among people, as well as a dynamic interaction between people and nature. The production required for human subsistence is the foundation upon which society ultimately stands. From the production of the modes of production, people produce their corresponding sets of ideas. People are the creators of their ideology, as people are continually changed by the evolution of their productive forces and of the relationships associated with these productive forces. People continually change nature and thus continually change themselves in the process.

Julian Steward

Julian Steward (1902–1972) is credited with the twin concepts of *multilinear evolution* and *cultural ecology.* Multilinear evolution is the exploration of recurring themes in cultural change. Cultural laws are then described in ways that make these changes clear. What become apparent are patterns of historical change that explain arrangements of the interaction between parts of a society and the larger environment. Cultural traditions are made up of basic characteristics that can be studied in context. Similarities and differences between distinct cultures can be studied in a meaningful way, and cultural change becomes more understandable. The evolution of recurrent forms, processes, and functions in different societies has similar explanations. However, each society has its own specific historical and evolutionary movement.

Cultural ecology is the adaptation of a unique culture, modified historically in a distinctive environment. This provides for observation of recurrent themes that are understandable by limited circumstances and distinct situations. The importance here is to discover specific means of identifying and classifying cultural types. "Cultural type" serves as a guide in the study of cross-cultural parallels and regularities. This allows investigation into the reasons for similarities between cultures with vastly different histories. This, of course, depends upon the research problem. But for problems related to historical change, economic patterns are important, because they are more directly related to other social, cultural, and political arrangements. This is the "cultural core." Cultural features are investigated in relation to environmental conditions. Unique behavioral patterns that are related to cultural adjustments to distinctive environmental concerns become more understandable. The cultural core is grouped around subsistence activities as demonstrated by economic relationships. Secondary features are related to historical possibilities and are less directly related to historical change. Changes are, in part, evidenced by modification in technology and productive arrangements as a result of the changing environment. Culture is a means of adaptation to changing environmental needs. Before specific resources can be used, the necessary technology is required. Social relations reflect these specific technological adaptations to the changing environment. These social relations organize specific patterns of behavior and its supportive values. A holistic approach to cultural studies is required to see the interrelationship of the parts.

Leslie A. White

Leslie A. White (1900–1975) looked at culture as a superorganic unit that was understandable only in cultural terminology. The three parts of a culture were the technological, the social, and the ideological. All three parts interact, but the technological was the more powerful factor in determining the formation of the other two. Thus, cultural evolution has all three parts playing important roles, with the technological influencing the sociological to the greater degree, and the sociological ultimately determining the ideological. Culture becomes the sum total of all human activity and learned behavior. It is what defines history. Through technology, humans try to solve the problem of survival.

To this end, the problem arises of how to capture energy from the environment and use this energy to meet human needs. Those societies that capture more of this energy and use it most efficiently are in a more advantaged position relative to other societies. This is the direction of cultural evolution. What decides a culture's progress is its capability of "harnessing and controlling energy." White's law of evolution, simply stated, says that a society becomes more advanced as the amount of energy harnessed per capita per year is increased, or as the efficiency of the activity of putting the energy to work is increased. This is cultural evolution.

Marvin Harris

Cultural materialism is based on the concept that human social existence is a pragmatic response to the realistic problems that are the consequence of pressures of the interaction between populations, type of technology, and the environment; with the economy as ever-important. Marvin Harris is the major spokesperson for this model, in which the social scientist investigates the basic relationship between particular social activity and overall tendencies.

Human communities are connected with nature through work, and work is structured through social organization. This is the foundation of the production of all societies. The way people come together to provide for their necessities, how these goods are distributed within the population, and networks of trade and exchange establish what is possible for the social organization. This relationship between environment, technology, population pressure, and social organization sets up the potential alternative ideologies within any culture.

How the basic needs are met within a society affects all members of that society, though often not equally. Ideology reflects not only the interaction between culture and nature but the understanding of this relationship. The model used is one that begins with the infrastructure, which includes environment, technology, and population pressure, Infrastructure is roughly similar to the Marxist concept of forces of production.

The structure or social organization is similar to the structure in the Marxist theory of relations of production or social organization. Structure is one step removed from the human interface with nature, and therefore the infrastructure has more influence on the structure than vice versa. The superstructure is what would be called ideology, or the symbolic and the ideational by other theories. The superstructure is twice removed from the human interface with nature and thus influenced more by both the infrastructure and the structure. The economy is the interaction between the infrastructure and the structure. This would be the mode of production of Marxism.

Unlike Marxism, cultural materialism emphasizes the primacy of the infrastructure over the structure in the formative relationship between the various parts of society. Changes in technology that are adaptive, given the environment and population pressure, are likely to be selected for and kept. This, in turn, will create long-range changes in both the structure and superstructure. Marxism, because it is dialectical, explains the relationship between forces of production and relations of production and is more reciprocal than cultural materialism. In Marxism, the forces and relations of production together make up the mode of production or, roughly, the economy. Again, cultural materialism would show, more than Marxism would, that the economy or infrastructure and structure more closely influence the substance of the superstructure. Only in cultural materialism do the forces of production determine the relations of production, and only ultimately does the mode of production control the superstructure using a Marxian model. The materialism of the Marxist is founded upon Hegelian dialectics; the philosophical foundation of cultural materialism is logical positivism.

Marxism, cultural ecology, and cultural materialism all begin with the first premise that the study of any social system is the dynamic interaction between people, as well as the dynamic interaction between people and nature. Because people come together in groups for human subsistence, they are social animals. This is the foundation upon which society ultimately stands. In producing what people need to live, people also produce their corresponding sets of ideas. In this way, it can be said that people are the creators of their history and ideology, though usually not in ways they are aware of. The process is historical, because people are continually changed by the evolution of their productive forces, and they are always changing their relationships associated with these productive forces.

Cultural core is the central idea of cultural ecology. This core is made up of economic patterns, because they are more directly related to other social, cultural, and political arrangements than are interactions between populations, types of technology, or the environment. The cultural core sets the limit of what is possible rather than directly determining what other theorists would call superstructure. Current scholars in the field add the use of symbolic and ceremonial behavior to economic subsistence as an active part of the cultural core. The result of cultural beliefs and practices continuing sustainability of natural resources become more likely. Symbolic ideology is as important as economics in defining the cultural core. Through cultural decisions, people continually become accustomed to a changing environment. Cultural ecology is closer to Marxism than it is to cultural materialism.

Finally, in the debate between Hegelian dialectics and logical positivism as the philosophical foundation for methodological materialism, the radical behaviorism of B. F. Skinner stands closer to the cultural materialism of Marvin Harris.

B. F. Skinner

The radical behaviorism of B. F. Skinner (1904–1990) begins with the idea that psychology is the science of behavior and not the science of the mind. The ultimate source of behavior is the external environment, not the world of ideas. Skinner maintained behavioral explanations of psychological observable facts as physiological influences. Behavior includes everything that an organism does. Thinking and feeling are other examples of behavior. All behavior is what psychologists try to explain. Skinner promoted the explanation that environmental characteristics are the correct causes of behavior. Environmental factors are external and separate from the behavior being studied, and one can influence behavior by manipulating the environment. Conditioning is caused by the influence of the total environment, including physiology. Conditioning is also influenced by culture and the ability of the organism to learn its own history. Each individual observes private events, like thinking, which is also a behavior. Introspection is also a behavior that is affected by the environment.

Radical behaviorism claims that behavior can be studied in the same manner as other natural sciences. Animal behavior is similar enough to human behavior that comparisons can be made. Ultimately, for all animals including humans, the environment is eventually the cause of the behavior that is studied; and an inclination for operant conditioning, or the modification of behavior. The occurrence or nonappearance of rewards or punishment is conditional upon what the animal does. This is achieved through reinforcement of already existing behavior, either by introducing a stimulus to an organism's environment following a response, or by removing a stimulus from an organism's environment following a response. Reinforcement will cause a behavior to occur with a greater rate of recurrence. Punishment or removal of the stimulus, also called negative reinforcement, will lead to a decrease in frequency, leading to extinction of such behavior. When an aversive stimulus is inflicted, a subject learns to avoid the stimulus. The avoidance learning may still be in place for a time.

Consistent with the theory of operant conditioning, any behavior that is repetitively rewarded, without error, will be more rapidly changed than when behavior is reinforced sporadically. This will lead to a more constant occurrence of a particular behavior and is comparatively more resistant to extinction.

Maturation

Maturation, the growth and transformation of a single-celled zygote to a multicellular organism, has fascinated humans for centuries. In only a matter of months, a single cell can develop and mature to a complex organism. Although the maturation period for each species is different, the result is the same: a complex living organism.

No matter the species, the early stages of maturation are common to almost all animals. The first step is fertilization, in which the male and female sex cells or gametes fuse, creating the single-celled zygote. In species living in an aquatic environment, external fertilization is the usual method, in which the female deposits eggs into the environment to be immediately fertilized by the male. This method of fertilization usually requires courtship and environmental cues to be sure a male is present for fertilization, as well as to prevent the destruction and drying out of the eggs. In dry environments, the only way for sperm to reach the egg is by internal fertilization. By this method, sperm are deposited in or around the reproductive tract of the female. After fertilization, the newly formed zygote creates a fertilization envelope to prevent polyspermy, or union with more than one sperm cell.

Two distinct development modes begin after fertilization, protostome development and deuterostome development. Examples of common organisms that feature protostome development are molluscs and arthropods, while chordates and echinoderms are common examples of organisms that feature deuterostome development, among many others. From this point, maturation begins with the first cell divisions, known as cleavage. Unlike normal cell division, cleavage divisions are rapid, with no time for cell growth between each division. This process virtually partitions off the single-celled zygote into smaller cells called blastomeres, each complete with its own nucleus. In deuterostome cleavage, the cells divide in a radial pattern, in which the planes are parallel or perpendicular to the vertical axis of the embryo. Cleavage in deuterostomes is also indeterminate, meaning these new cells are not yet fated and can form an entire organism if isolated. In protostome development, the cleavage pattern is spiral, in which the planes of division are diagonal to the vertical axis of the embryo. Cleavage in protostomes is also determinate, in that these new cells are already fated and cannot form a whole organism when isolated.

This cleavage continues, forming a multicellular ball of blastomeres, known as a morula. Eventually, the number of blastomeres grows to form a single-layered ball of cells known as a blastula, featuring a hollow cavity in the center, known as a blastocoel. In humans and mammals specifically, this stage forms a blastocyst, with the key difference being the presence of an inner-cell mass within the blastocoel, as well as an outer epithelial lining to the blastocyst, known as the trophoblast. Also, in many other species, different concentrations of yolk, stored nutrients for maturation, tend to offset cleavage patterns. This is due to high concentrations of yolk found at the vegetal pole of the blastula and low concentrations of yolk at the animal pole. Thus the blastomeres at the animal pole tend to be smaller then the blastomeres at the vegetal pole. Yolk concentration can be so high that cleavage is hindered and even incomplete, a phenomenon known as meroblastic cleavage. Alternately, cleavage that is unimpeded by yolk and continues to completion is known as holoblastic cleavage. This uneven distribution of yolk is very distinct in different species and characterizes how they develop.

Although at these stages of maturation we start to see characteristic differences in each species, gastrulation generally follows cleavage blastulation. Gastrulation is the rearrangement of the blastula to form a gastrula consisting of two or three germ layers: the ectoderm and endoderm, with the mesoderm as the third and middle layer. Gastrulation also forms a primitive gut, known as the archenteron. This rearrangement allows the cells to interact in new ways and causes changes in cell shape, motility, and adhesion. One process of rearrangement is invagination, in which the single-celled blastula buckles into the blastocoel to form a second layer. This invagination causes the direct formation of the archenteron as well as the blastopore. This blastopore becomes the primitive mouth in protostomes and the primitive anus in deuterostomes. A second mechanism is involution, in which cells "roll" over the lip of the blastopore into the interior of the embryo. The combination of these two processes forms the gastrula. The archenteron and coelom, the primitive body cavity, differ in deuterostomes and protostomes. In deuterostomes, the body cavity formation is described as enterocoelous, in which the mesoderm forms outpockets from the archenteron and forms the body cavity. In protostomes, the formation of the coelom is described as schizocoelous, in which mesoderm near the blastopore split and outpockets to form the coelom.

Organogenesis is characterized by the development of primitive organs, vessels, and body systems in the embryo. Each of the three germ layers of the gastrula gives rise to the beginnings of very specific organs throughout the body. The ectoderm, the outermost layer of the gastrula, develops into the epidermis (skin) and sense receptors, as well as a majority of the nervous system. The mesoderm, the middle layer of the gastrula, gives rise to the skeletal and muscular system, as well as the reproductive system, circulatory system, and excretory system. The endoderm, the innermost layer of the gastrula, forms the epithelial lining of the digestive and respiratory tracts and the liver pancreas, as well as several glandular organs. One of the first organs to develop is the neural tube. The ectoderm thickens and pinches inward, forming the primitive spinal cord.

In mammals, all of these maturation processes occur during pregnancy, or gestation. The length of the gestational period directly correlates to the size of the growing organism. The typical human gestational period is about 40 weeks. However, the typical gestation period of a rodent may be only 21 days, while the gestation period of a cow averages about 270 days. Gestation in elephants can last as long as 600 days. In humans, pregnancies are usually split into three trimesters of about 3 months each. Organogenesis is usually completed by the end of the first trimester. At this point, the embryo is no longer considered a gastrula, but a fetus; fetuses average only 5 cm in length. In the second trimester, the fetus becomes more active within the womb and grows to approximately 30 cm. The final trimester results in birth of the child, or parturition. It is believed that hormone levels within the blood control labor, the process of birth. However, the mechanism behind this is not yet fully understood. Labor consists of three phases: the thinning and dilation of the cervix, the delivery of the baby, and the expulsion of the placenta.

Modern science has provided this insight into these complex processes, but this has not always been the understanding of maturation. As far back as 2,000 years ago, Aristotle proposed the idea of epigenesis, in which the animal develops from a relatively formless zygote. This theory, which was more accurate than most then believed, contrasted with the theory that prevailed to the 18th century, that of preformation. In preformation, it was believed that within the egg or sperm was a preformed miniature infant or homunculus and that this homunculus simply grew and matured within the womb until it was born. It wasn't until the 19th century, with the invention of light microscopy, that scientists were able to get a more accurate understanding of the complex process of maturation.

Maximus the Confessor, Saint (c. 580–662)

Born in Constantinople (present-day Istanbul, Turkey), Saint Maximus (Maximos) the Confessor influenced Eastern Christianity through his writings, debates, and personal witness as a Byzantine monk, spiritual writer, and opponent of monothelitism. Maximus's primary writings consist of Biblical commentary (*Quaestiones et Dubia, Quaestiones ad Theopemptum Scholasticum, Quaestiones ad Thalassium),* Christological debates (*Opuscula Theological et Polemica*), explanations of the liturgy (*Mystagogia*), and ascetic practice (*Liber Asceticus*). From his writings, it is evident that Maximus showed a great interest in the concept of timelessness and its relationship to the temporal world.

Maximus came from a wealthy household in Constantinople and received a good education. From 610 to 613, he worked as a secretary for Emperor Heraclius I, but he retired to the monastic life. Maximus resided in two monasteries in Turkey: Philipikos in Chrysopolis and Saint George in Cyzcius. Threatened by the Persian invasion of 626, Maximus moved to North Africa, making stops in Crete and Cyprus before reaching Carthage in 628. From North Africa, he defended the Christological teachings of the Cappadocian and Chalcedonian fathers against the Christological heresy of monothelitism, which taught that Jesus Christ had two natures but only one will, in contrast to the orthodox view that Jesus had two natures and two wills, human and divine. Maximus disputed this heresy with expatriarch Pyrrhus I, and later condemned monothelitism at the synod of the Lateran, in Rome, in 649.

Refusing to sign the conciliatory declaration of Emperor Constans II, Maximus was arrested in 653, charged with treason, and exiled to Bizye (Byzia), in Thrace, in 655. Tried and convicted again for treason in 662, Maximus endured torture and amputation of the tongue and right hand. This time the Byzantine monk was exiled to Lazica (on the eastern coast of the Black Sea) where he remained until his death in 662. Following his death, the Eastern Church called Maximus "the Confessor," for his faithfulness under torture in defending the orthodox teaching on the nature of Christ.

Maximus studied the classical Greek philosophies and labored to find their relation to or compatibility with the Christian worldview. Particularly interested in Neoplatonism, Maximus looked at the connection between Plotinus's "one" and the "many" (or creator and created). This examination made Maximus believe in the concept of timelessness, in which the individual achieves a supratemporal state or existence. The Eastern doctrine of deification complemented his view of timelessness, because the individual works to become one with God through prayer, meditation, and other ascetical practices. The "one" (God) became like the "many" through the incarnation (*logos*), and the "many" possess the ability through grace to become divine like the "one" because of the resurrection and ascension.

Although Maximus thought individuals reached a supratemporal state, he also recognized that the individual lives in a temporal world and experiences a beginning and an end, following a sequence of events in history. In his writings, Maximus makes this distinction using the term *aion* in reference to an endless amount of time and the term *chromos* in reference to the daily passage of time and events in history. Maximus, like other Neoplatonist Christians, had to reconcile the Greek understanding of a cyclical calendar with the Judeo-Christian understanding of linear history. For Maximus, the Christian scriptures focus on the history and chronology of past events, as well as point toward a fixed goal in the future (the eschatology). Both views of time share the concept of process and movement. Maximus acknowledges that God created the universe and interacts in history, but time does not restrict God. Therefore, the individual follows the movement of time and events in a linear sense, but through the process of deification, time does not restrict those who achieve union with God.

Because he was recognized as a saint, Maximus's life and works greatly influenced Eastern orthodox theology, and this Byzantine monk worked diligently to defend the nature of Christ. In his writings, Maximus the Confessor played a key role in bringing together Greek philosophy and a Christian worldview and contributed to the discussion or study of timelessness in a temporal world.

Maxwell's Demon

Maxwell's demon is the name of a thought experiment that has been intensely discussed by physicists and philosophers investigating the relation between energy, information, and time. In this experiment, an imaginary but not supranatural being is using his extraordinary sensorial and intellectual powers to violate the second law of thermodynamics and, therefore, to falsify the fundamental principle by which modern physics explains the irreversible direction of time. The demon is named after one of the greatest physicists of all time, James Clerk Maxwell (1831–1879), who developed the theory of the electromagnetic field and conceived, in 1867, the experiment with the fictitious being.

The problem Maxwell wanted to solve by his thought experiment is whether a physical process might be conceived that, though being consistent with all known laws of physics, breaks the second law of thermodynamics. This law states that the entropy of a thermodynamically closed system never decreases so that it is possible to objectively measure the irreversible flow of time by comparing the entropy of different states of such a system. How did Maxwell suppose his demon to perform the feat of violating the second law? The demon, who has superhuman abilities but must act according to the laws of physics, is sitting in a closed container that is filled with gas and divided, by an impermeable partition, into two halves. In the partition there is a door that can be opened and closed at will. The demon observes the gas molecules approaching the door in both halves and sorts them by deciding which molecules are allowed to move through the door so that, for example, the faster ones will be gathered in the left half and the slower ones in the right half. Because the left half gradually becomes warmer and the right one cooler, the resultant temperature difference can be used to do work. Suppose that Maxwell's demon and the door could operate in a reversible manner, giving up some amount of energy when opening the door without friction and taking in the same amount of energy when closing it without friction. Then the container would constitute, for all practical purposes, a *perpetuum mobile* that, thanks to the demon, could completely transform heat flowing from a reservoir at lower temperature to a reservoir at higher temperature into work.

Even a short description of Maxwell's demon shows that information plays a crucial role in reasoning about the thought experiment. The demon must know the positions and the velocities of the molecules that are approaching the door to decide reasonably whether it is to be opened or closed. To bring order into a disordered system (thermodynamically speaking, to lower its entropy), information about the components of the system is needed. Therefore the physical nature of information must be taken into account if we want to find the weak spot of Maxwell's demon and to show that the thought experiment is not a counterargument against the universal validity of the second law of thermodynamics. The history of the discussion about Maxwell's demon mirrors the difficulties encountered in the development of a physics of information. Arguments for the possibility of Maxwell's demon, and against it, revolved around the information-gathering activity of the imaginary being: How does the demon come to know the location and speed of single molecules, and is the thermodynamic cost of gathering this information high enough to rescue the second law of thermodynamics because it produces at least the same amount of entropy that it makes possible to consume?

In 1982, a quantum physicist and computer scientist, Charles H. Bennett, brought forth the conclusive argument against the possible existence of Maxwell's demon. Bennett showed that it was not the gathering, as everyone had thought before, but the erasure of information that is decisive for an adequate understanding of the demon. The reason for this is that the demon needs a memory in which information about the molecules can be stored. Because the demon is, though fictitious, a physical being, this memory is finite. At some time the demon must begin to forget—that is, to erase information about the locations and velocities of molecules he has observed; otherwise, he could not memorize new information about molecules approaching the door. "Erasing information" means here that it is impossible for the demon to gather the deleted information once again. Bennett calls this kind of irreversibility that concerns the inability to infer a former state of a system from information about its given state, *logical irreversibility.*

Because different pieces of information must be represented by different physical states, logical irreversibility is combined with thermodynamic irreversibility. The higher the number of different equiprobable pieces of information a system can have, the higher its entropy is. Erasure of information thus decreases the entropy of the demon's memory: At first, the memory unit containing the information could have been in a number of different equiprobable states ("molecule x is in state y at time t"); then the erasing process resets it to a predefined state ("unknown molecule is in unknown state at unknown time"). Because the erasure of information in the demon's memory shall be logically irreversible, this process must emit an amount of heat into the environment of the demon that increases the environment's entropy to a higher extent than the entropy of the demon's memory is decreased. Bennett shows that this net increase at least counterbalances the decrease in the environment's entropy that happens thanks to the information-gathering activities of Maxwell's demon. Altogether, the entropy of the whole container is at best constant, and the second law of thermodynamics is rescued. By the power of information-theoretical and thermodynamical reasoning, Maxwell's demon thus shows us that the irreversibility of time is the same as the loss of information that we, as finite beings, must inevitably experience.

McTaggart, John M. E. (1866–1925)

John M. E. McTaggart, a British Hegelian philosopher and one of the most independent minds of his generation, produced, among other things, a logical and coherent argument for the essential unreality of time. He was the son of Francis and Caroline Ellis; the surname McTaggart was added by his father in order to fulfill a condition for an inheritance. The now prosperous family sent young McTaggart to the prestigious Clifton School and Trinity College, Cambridge. While visiting his widowed mother in New Zealand in 1892, he met Margaret Elizabeth Bird. The two married during his next visit to New Zealand, in 1899. His entire academic career, between 1897 and 1923, was at Cambridge, where he developed his brilliant, though idiosyncratic, blend of quasi-Hegelian idealism and atheism.

A genial man, McTaggart was a longtime friend of G. E. Moore (1873–1958), despite the latter's role as the most influential critic of British Hegelianism. And along with Moore and Bertrand Russell (1872–1970), McTaggart was a member of the irreverent Cambridge club known as the Apostles. But his friendship with Russell came to an end during the First World War, when McTaggart led a campaign to have Russell thrown out of Cambridge University for his vocal opposition to conscription. McTaggart died suddenly and unexpectedly in January 1925.

One of the many paradoxes of McTaggart's life is that he produced no disciples and yet generated some of the most exhaustive commentary of any British philosopher of his generation. His importance among philosophers was given graphic illustration in C. D. Broad's massive three-volume *Examination of McTaggart's Philosophy* (1933, 1938), which remains one of the most comprehensive expositions of a 20th-century philosopher's body of work. Broad succeeded McTaggart at Trinity College. McTaggart's views on time were defended as recently as 1960 by the British antirealist philosopher Michael Dummett. McTaggart was a philosopher's philosopher, and he devoted little time toward engaging the interest of nonspecialists. But among professional philosophers he is best remembered for his work in logic, which remains influential to this day. An important example of McTaggart's logical power is his theory of the unreality of time.

Aspects of McTaggart's Philosophy

McTaggart's earlier career was spent articulating a comprehensive though idiosyncratic interpretation of the philosophy of Hegel. *Studies in Hegelian Dialectic* (1896) reworked the notion of proceeding with successive stages of thesis, antithesis, and synthesis. *Studies in Hegelian Cosmology* (1901) was more radical in its reexamination of Hegel's concept of the absolute idea, and *A Commentary on Hegel's Logic* (1910) dissected Hegel's argument from pure being to the absolute idea.

The closest McTaggart ever came to writing a popular work was with *Some Dogmas of Religion* (1906, with a second edition in 1930). Once again, being an atheist with respect to questions of the existence of God or gods while also maintaining a highly individual conception of immortality, he came to conclusions that were characteristically idiosyncratic. His justification for religion was dauntingly rigorous. Any religious belief, he argued, required the prior belief that the universe is good. But there is no reliable method by which one can believe this other than dogmatically. And dogmas, in turn, require a metaphysical investigation, for which most people lack the time or inclination. Therefore, regardless of whether the religion is actually true, the vast majority of people accept their religion on false grounds. This in turn will lead to a larger number of people living without religion, but also without its consolations, and who are therefore unhappy. This said, McTaggart was no more convinced that there was a link between religious belief and happiness.

But as against this line of argument, McTaggart advocated a mitigated version of immortality. After criticizing most arguments against, as well as many of those for, personal immortality, he advocated a disembodied mind that linked with a universal spirit that was composed principally of love. His contribution to the development of 20th-century atheism is more substantial than he is given credit for, although the fault for this lies with McTaggart himself.

McTaggart on Time

Many of these arguments came to rest on McTaggart's core belief in the unreality of time, which were first given serious expression in *Mind* in 1908 and developed in the 33rd chapter of his main work, the two-volume *The Nature of Existence* (1921, 1927). Like much of his work, this book was broadly Hegelian in outlook rather than proceeding specifically from a particular argument of Hegel's. He worked along Cartesian lines, postulating the existence of any one thing to existence of pluralities of things, to the existence of "the Absolute," which is the sum total of all the various substances without being anything more of itself than any of its constitutive parts.

Attempts had been made before McTaggart to construct arguments along these lines, though none with anything like his attention to logical detail. For instance, it has been claimed that a series of paradoxes by Hui Shi (c. 380–c. 305 BCE) was an argument for the unreality of time as part of a general program of problematizing the distinctions between space and time. And arguments for the unreality of time were advanced by the Sarvastivadin school of Buddhism about 500 CE. Only with McTaggart, however, was a concerted and deliberate aim made to argue for the unreality of time. His argument began with the observation of two types of temporality. There are events (which he called the A series) that figure either as past, present, or future, while others (the B series) operate either as earlier or later. Only the A series of events are essential to the idea of time, because only those sorts of events require a distinction between past, present, and future. Consequently, any difficulty in regarding the A series as real means an equal difficulty in regarding time as real. Past, present, and future can, more or less, be described, McTaggart admitted, but they cannot be defined.

The next step in the argument is crucial. McTaggart then argues that past, present, and future are clearly incompatible, and yet the A series needs each one at every event. To the objection that past, present, and future happen successively rather than simultaneously, he replied that any one moment still has its past and future and, as such, remain incompatible, and insofar as time depends on this series, time cannot be real.

He then infers that if a B series without an A series can constitute time, then change must be possible without an A series. A change of this sort means that an event (a position in time in McTaggart's usage) ceases to be an event while another one begins to be an event. But this cannot be, as nothing can cease to be an event or begin as an event. So without the A series there can be no change, because the B series is not sufficient in itself for change. And as events in the B series are time-determinations, it follows that there can be no B series where there is no A series, because where there is no A series, there is no time.

Now McTaggart does allow for events having an order—this he calls the C series—and events in order may become relations of earlier and later, in which they would become a B series. But this order does not necessarily imply that they must change, because change must be in a particular direction.

Having demonstrated that there can be no time without an A series, McTaggart then goes on to prove that the A series cannot exist. The characteristics of A series—the supposed sequence of past, present, and future—are either a relation or a quality. Either way, a fatal contradiction exists. Each event is the same, whether in the past, present, or the future, and its relation to each event's past and future must also always be same. McTaggart also argues that past, present, and future are incompatible. Each event has a past and future, and is in this way predictable, and yet events are also incompatible with each other. It presupposes the existence of time to erase the incompatibility, and yet the existence of time is what this argument sets out to demonstrate.

McTaggart conceded that it may well be possible that the realities we perceive as events in time are part of some nontemporal series in the manner of the C series. This seemed compatible with Hegel, who argued for a timeless reality, of which the time-series is but a distorted reflection we have of it. But this did not affect the core argument that the A series is "as essential" as the B series in that the distinctions of past, present, and future are essential to time, and that, if these distinctions are never true of reality, then one cannot include time as part of reality.

As mentioned above, McTaggart's theory of the unreality of time has not found general acceptance. It is not coincidental that his most loyal defender after Broad was Michael Dummett (1925–) the British exponent of antirealism. Others, like Roy Bhaskar (1944–), have found value in McTaggart's distinction between the A and B series without endorsing his conclusions about time's unreality. Opponents of the theory claim it amounts to little more than a play on tenses. J. J. C. Smart (1920–), for instance, argues that the idea of change can be expressed in the language of the B series by speaking of points in time *differing* from each other, which does not require us to say that events change. In effect, McTaggart's nonuse of tensed verbs with respect to the B series and use of them with respect to the A series is what sustains the apparent contradiction his argument rests upon. A simple reversal in the distribution of tenses, and the problem disappears.

McTaggart's denial of the existence of time is the best known of his arguments, although he did not stop there. *The Nature of Existence* also featured arguments that denied the existence of material objects, space, and a range of mental processes. These claims rested on a quite different argument, however. These entities could not exist by virtue of not meeting the requirements of a relation he called determining correspondence, a complex relation of any substance to the almost infinite range of divisible parts it could possibly be divided into.

Conclusion

Notwithstanding the solid support of Broad and Dummett, McTaggart's arguments have not found wider favor. The very strength of the argument—its logical power—was also its weakness, because the argument rested on logical grounds alone. Even if we overlook Smart's powerful objection to those logical grounds, McTaggart's argument for the unreality of time is fatally undermined by virtue of having taken too little account of the facts of science. At much the same time McTaggart was working out his theory of the unreality of time, developments in physics were establishing that time was very real indeed. The second law of thermodynamics and its corollary in entropy makes it clear that time is a fundamental part of the universe and that it is unidirectional. The fate of McTaggart's theory of the unreality of time is an object lesson in the need of scientific understanding, or at least of a multidisciplinary approach, when doing serious philosophy. Though not a contender as an explanation of the universe, McTaggart's argument for the unreality of time is an impressive intellectual achievement.

Media and Time

In the context of 19th and 20th century modernity—its technical revolutions and specific ways of experiencing time—the insight has grown that our ideas of time are decisively shaped by our interaction with media: Media influence our understanding of time. Particularly in investigations in cultural and media theory, there have been attempts to work out the dependencies between media and conceptions of time. The following cultural-historical transformation can be considered as paradigmatic for the assumption of media-time dependency: the change in our experience of time through the invention of the clock.

Thanks to a uniform mechanical process, time became precisely measurable, independent of subjective impressions of time and independent of sequences of natural events (e.g., day/night). The cultural establishment of clock time since the 13th century has not only changed social processes but also changed and extended our consciousness of time. In contrast to the experience of event time, cultural awareness of qualitatively indifferent, infinitely divisible time has grown through clock time, which made possible a massive economization of time with all the known accompaniments, such as lacking time and acceleration. In a media-theoretical perspective, this historically indubitable finding serves as evidence for the assumption that a certain conception of time (idea of abstract linear time) depends on the invention of a medium (the clock). But whether the clock, as a "time machine" (Marshall McLuhan), can form a model for proving a media-time dependency is problematic. The question is whether a clock is a medium at all. A clarification of the relationship between time and media, and a differentiation of ideas of time using media parameters, cannot take place without a preceding differentiation of the concept of media.

Both in everyday language and in the sciences, the ways in which the term *media* is used are very varied and not to be subsumed under one category. If, along with the media philosopher Marshall McLuhan, one pursues a very broad media concept, according to which media are technical inventions (artifacts), indeed artificial extensions of the human, then the clock (as a technically optimized form of time measurement) can also be treated as a medium. The advantages of such an approach lie in the possibility of treating very different technical inventions (e.g., the car and the telephone) in their cultural context. The disadvantage of such a broad understanding is conceptual imprecision. The differentiations between medium and tool and between medium and machine remain largely unclear. How broadly one grasps the media concept ultimately depends on which questions and aims one has and which facts are relevant in an academic context. The connection between medium and time thus cannot be described generally but only by considering the respective perspectival character. This entry distinguishes four perspectives in which the connection between temporality and mediality is respectively outlined.

The Media-Theoretical Perspective

Although the definition of the media concept is still quite controversial in media studies, there is nonetheless widespread agreement as to what counts among the central determinations. The material and technological basis of information and communication processes belong essentially to mediality. Relevant to this, however, are not only media in the sense of equipment and its technological changes and progress but their consequences for human information and communication processes. That is, mediality encompasses both the equipmental aspects of communication (in the broadest sense) and communicative practice as such.

In a media-historical perspective, significant changes in our ideas of time become clear. From a macroperspective, three phases can be distinguished above all. In a first phase, in which communication is primarily shaped by nonwritten media (gestures, voice, etc.) and ritualized oral tradition, cyclical ideas of time dominate. In the context of a culture of orality, events and series of events are largely considered as occurrences within larger cycles. In a second phase—starting with the development of phonetic writing (alphabet) in the 11th century BCE, via the invention of movable type printing in middle of the 15th century, through to writing as a mass medium since the 18th century—the idea of linearity develops into the dominant conception of time. Time is comprehended less according to the structure of cyclic recurrence and more as a linear order of the succession or sequence of events. By contrast, in a third phase—starting with the invention of new communications technologies (telegraphy and the telephone) and representational media (photography and cinematography) in the 19th and 20th centuries (radio and television in the first half of the 20th century, the computer and the Internet in the second half)—the ideas of simultaneity and nonlinear temporality develop. The transitions between these three phases are quite fluid, with overlap and interference being the norm. Already on historical grounds it is not convincing to assume, as is sometimes suggested, that different media paradigms like orality, scripturality, or digitality imply a strict difference in conceptions of time.

Whether the connection between media development (from a culture of orality, via written culture, to the digital world) and a changing conception of time (from the cyclic idea of time to the idea of linearity and finally to simultaneity) is to be considered as monocausal dependency or merely as a (theoretically difficult to grasp) correlation is controversially discussed. There are different arguments—according to which media concept is taken as basic—for there being a connection.

1. If one first considers media as *information and communications media,* then two lines of argument can be highlighted as examples using developments within writing culture. The first relates above all to the performative aspect, or the type of activities, in media use. The cultural techniques (writing and reading) linked with writing are shaped by the primarily linearly shaped *performance* of information processing. Information is here initially ordered not pictorially or sculpturally but in a strict linearity. The cultural dominance of the medium of writing and the performances linked with this forces the priority of the linearity of temporal succession (over the temporally indifferent division of space) in the sense of a temporal schema that regulates both the production and the reception of writing. That writing and reading are not only linear but also highly complex cognitive feats shaped by forward and backward references is not a compelling objection to the linear conception of time; this complexity is rather the condition for developing an idea of linearity (cf., Edmund Husserl's concept of retention/protention).

The second line of argument for a time-media correlation results from the observation that certain media practices encourage the emergence of certain epistemic rules and systems of order. In the context of writing culture, media practices interact with the *order systems* of knowledge, which are characterized by essentially linear ideas of temporality. For the ideas of open, transpersonal, and cross-generational development processes (i.e., not only the tradition of knowledge but also growth and progress in knowledge) are reinforced by the media production, storage, distribution, reception, and reprocessing (reinterpretation or change) of knowledge. Furthermore, the media practice of writing culture is one factor in the dominance of a model of perfectibility that is based on generally accessible and examinable (i.e., also methodically reproducible) knowledge and aims at an open, infinite progress in knowledge.

The perfectibility here ultimately lies less in what has in fact respectively been attained than in the possibility of constant improvement. Further, it is a factor in the development of a modern self-consciousness, which not only addresses its temporary and local environment in writing but nourishes its self-consciousness not least from the fact that as an individual it simultaneously understands itself as an expression of humanity and addresses all of posterity ("writing for eternity"). Linear conceptions of time gain in importance both through the knowledge orders (cf., in particular the idea of encyclopaedic knowledge pursued by Diderot and others in the spirit of Enlightenment), which developed in writing culture (above all after the invention of movable type printing) and aimed at general comprehensibility and infinite progress, and through the individual that, so to speak, in writing comports herself toward the whole of humanity. These linear conceptions of time are not restricted to local conditions and events, or to the mere recurrence of events, but take account of open processes and events that build upon one another. The dominance of a linear conception of time in the context of writing culture manifests itself particularly in the historical thinking that is typical of modernity and that has been spreading into practically all areas of knowledge since the late 18th century.

2. Alongside the first line of argument for media-determined changes in and shaping of ideas of time, which is based on the aspect of media *practices* (performances) and the forms of discourse and *order systems* shaped by media practices, a further line of argument results when one treats media primarily as *representational media* and not as *information and communications media.* Representational media, which are distinguished less technologically than functionally from communications media, are more precisely characterized by not only transmitting given (physical, biological, technological, social, or historical)

information but by generating meaning or semantic units. In this perspective media are considered not with regard to their transmission function but with regard to their function in the production of certain contents (media contents).

Representational media (e.g., dance, music, written text, film) produce semantic units, that is, they generate individuable and reproducible complexes of meaning. If one focuses on the level of semantic units articulated by representational media (instead of the paths of transmission for given information and media practices), then different (both fictional and nonfictional) temporal conditions, in part media-specific ones, can be recognized. Examples are, say, the distinction between *narrative time* and *narrated time* in literature, and the possibilities for extreme time contraction and time extension, or—partly analogous to literature—the extreme leaps in time in film though jump-cut or flashback methods. Thus well-known films such as *The Matrix* also show in exemplary fashion how specific forms of imagination and temporal conditions can be generated through the specific representational possibilities of a medium. Think, say, of the so-called bullet time, in which natural speed conditions are suspended and a normally invisible bullet is slowed down extremely in its motion, becomes visible, and is overtaken or moved around by naturally much slower bodies (e.g., humans). What such examples make particularly clear is the possibility of using representational media to generate temporal conditions that must be considered to be naturally highly unlikely, if not even impossible. That is to say: Representational media articulate temporal relations in a manner largely independent of the basic physical beliefs that are indispensable in our everyday life.

At this level of consideration—the level of media-dependent and, so to speak, physics-independent semantics of imagined time constellations—two aspects should be emphasized: (1) First, focusing on representational media shows that certain ideas of temporal processes are generated in a way dependent on representational methods and possibilities. At the semantic level, not only are established patterns of temporal information processing (according to the model of "natural" sequences of events) presented, but new "naturally" "meaningless," but semantically "meaningful" ideas of temporal arrangements are (also) generated. (2) Furthermore, the representational capacities of representational media permit humans a particular relationship to temporality. Using representational media, we can become aware of dimensions of time that are naturally inaccessible to us (past sequences of events or possible future scenarios). They enable us on the one hand to submerge in a past (either historical or fictive) beyond our own biographical horizon, but on the other hand they also enable us to imagine our future and to exchange views about possible future scenarios.

The particular cognitive ability of humans to process information with the help of time concepts and to comport themselves toward nonpresent events finds its adequate expression in the use of representational media: Released from what is respectively present, meaningful patterns of events are articulated in representational media, the meaning of which reaches beyond the time field of individuals. It is only through the production and storage of such semantic units that we can comport ourselves toward the past and future independently of the narrow horizon of our own experiences (cf., for example, the mythical past articulated in the Homeric epos or in aborigines' songs).

3. A third line of argument for the time-media correlation relates less to systematic connections, starting from relatively broadly conceived and functionally differentiated media concepts (information and communications media, representational media), and is based rather on a primarily historical and quantitatively defined class of media. Central to this are modern mass media (newspapers or the press, posters, radio, television, Internet) through which information can be spread in quantitatively high numbers (in "masses") and within a very short time. Four different aspects should be emphasized here:

- A first temporal aspect of mass media consists in the particularly fast, tendentially synchronous informing of a large number of information receivers.
- A further temporal aspect of mass media becomes recognizable when one considers complex communications situations (primarily not dialogical,

but marked by feedback processes). The understanding of information spread by mass media is essentially shaped by the demands of being up-to-date and the high frequency and fleetingness of the associated importance of information. The value of a piece of information (but also of a transmission format) is here measured in terms of its up-to-dateness. The rhythm of information determined by this (e.g., periodic appearance of newspapers or magazines, continuous transmission in radio or television) and the respective program structure (e.g., news or entertainment programs) have an effect on the audience's everyday life and feeling for time. Overall it holds that the semantics of information in the context of mass media is shaped by its specific communicative functions. The importance of information is here temporally indexed in a particular way. It is coupled to the relatively short intervals of time during which information, subjects, fashions, or program formats are perceived as being up-to-date.

- A third aspect is seen in the context of electronically based mass media (radio, television, Internet): News about real events, but in particular television pictures of events, is made accessible to the audience not only close to the time the events occur, as with newspapers, but instantaneously ("live") and "in real time." Being able to observe spatially distant events almost instantaneously through mass media is part of everyday experience these days. This fact encourages the idea (which is misleading, because it abstracts from the medium's selective mechanisms) of being able to adopt a quasi-divine standpoint in which all events in the world can be made simultaneously accessible, independently of their spatial position.
- A fourth aspect results from the *internal temporality* of the basic technical processes of information transmission, which have changed significantly through progress in the history of technology. The time interval between information production and reception has constantly become shorter; information transmission is so accelerated that the transmission time is converging on zero. An example of technical progress is the contrast between the sending of letters made possible by stagecoaches and the digitally based information transmission in an e-mail. The duration of information transmission diverges considerably. Instantaneous information transmission, live programs and real time, and the ideas of time shaped by their mass-media presence here appear to be determined in equal measure by the internal temporality of the underlying technology. This fact seems to confirm a thesis that has been much discussed in media studies, namely that ideas of time might be determined by the speed of technical processes. This thesis, which ultimately amounts to a medium a priori (the assumption of a medium basis that precedes, makes possible, and structurally determines our cognitive abilities), should however be rejected, because it starts with a very one-sided and abstract basic idea (i.e., from a media concept that lacks evolutionary and conceptual embedding; see point 2 below).

The Social-Pragmatic Perspective

In this perspective, the media-theoretically propounded thesis of a medium a priori is largely retracted and relativized. As a consequence, the assumption that experience and ideas of time are primarily determined by the history of media or the respectively guiding media is no longer dominant. For within this perspective, the accent lies not on the technological aspect but on the aspect of the human practices in which media are functionally defined and embedded. Here primordial connections between human actions are the starting point for focusing on the dependencies between media and ideas of time. Two approaches can be distinguished here: (1) a socioeconomic approach and (2) a communications-theoretical approach.

A brief general comment beforehand: For a theory that examines human practice and the social forms shaped by this, time plays a central role—and not only because of the historical nature of these phenomena. Humans must possess a concept of time so as to be able to act at all (e.g., so as to make end-means distinctions); beyond this they must possess a particular degree of time concepts (such as the differentiation of past, present, future) and be able to communicate these in order to act socially, that is, to be able to coordinate their actions with other agents.

Against this background, the extent to which media are an important factor precisely in a social-pragmatic perspective can be better understood: In order to coordinate actions socially, not only is the cognitive competence to be able to deal with temporal processes needed, but also an exchange of information between agents, in part over large temporal and spatial differences, is required. The functioning of communication between agents also depends essentially on the functioning of communications media and the speed of information transmission. Which actions are possible and are realized also depends on how, and above all how quickly, the communicative routes run.

1. Within a socioeconomic approach, the media-time correlation is treated above all in the context of an acceleration theorem. The sociologist Hartmut Rosa argues that we are today living in an age in which all social processes are being shaped by a ubiquitous tendency toward acceleration. This line of argument can initially draw support from the media-theoretical finding that especially through the introduction of digital media, and that means through the detachment of information transmission from bodily media (such as postmen, for example), a maximal acceleration of data transfer has come about. But the fact is now interpreted in the context of complex social systems and leads to the thesis that technical acceleration is embedded in different acceleration processes (acceleration of life processes as well of social and cultural changes) with in part paradoxical consequences (e.g., processes slowing down as a result of maximal increase in complexity).

2. If one advocates a stronger communications-theoretical approach, there is a shift in the lines along which problems of the media-time correlation are developed. Here too the question of mediality is embedded in a superordinate reference system. Yet it is not so much social systems that are central, but rather anthropologically founded discourse structures that regulate communicative actions and within which meaning contexts are produced and handed on. In relation to modern media and multimedia methods of representation (especially on the Internet), the thesis of a fundamentally altered experience of time is advanced. Various authors (the communications theorist Vilém Flusser, the sociologist Jean Baudrillard, the speed theorist Paul Virilio, the German literature and media theorist Götz Grossklaus) agree that the altered experience of time is characterized by a new primacy of the present.

There are three arguments above all that support the thesis of a primacy of the present:

- The first (media-epistemological) argument is general. (It gets by without closer differentiation of media and usually occurs in combination with other arguments.) It emphasizes that the experience of time within media communication is fundamentally relative to the present. In particular, the dimension of the past (e.g., certain events) as such loses importance in the context of digital media and is primarily experienced and perceived as a mode of current execution.
- Alongside that, so to speak Augustinian and rather non-medium-specific argument, a media-ontological argument is also discussed. Starting with the media-specific network structure of communicative processes (cf., digital media, particularly the Internet with its almost instantaneous and worldwide transmission of sound, images, and/or text signs), the aspect emphasized here is that there is a tendency to synchronize spatiotemporally distant processes within such forms of communication (Niklas Luhmann, Götz Grossklaus). The primacy of the present appears in this line of argument as the *primacy of simultaneity:* For the audience and agents within the network structure, the present extends into a field of the present in which remote events are synchronized within a time window (cf., the preceding argument) into a media reality.
- The third argument for the primacy of the present also has media-ontological implications. However, it focuses not on the synchronization effects of media communication but on the *modality* of media reality for the media user (sender, receiver; information producers and consumers). What matters here is the conviction that in the conditions of global networking of mutually independent information producers and storage, as well as communicative agents, the dominant impression for the individual agent is that of stepping into an open space of possibilities. The experience of presence here has nothing, or hardly anything, to do with the idea of a progression of transient present points but rather culminates in the idea of a field of the present generated

by selective individual decisions and which are surrounded by an open horizon of possibilities. That is, the experience of time leads to an idea of time in which the classical directional vectors (e.g., a line of progression from the past through the present to the future) do not dominate. Rather the accent is here on an idea of time in which a field of presence is surrounded by a variable horizon of possibilities, that is, by the future in all directions, and in which the dimension of the past appears as a residue (lost possibilities) at most (cf., Vilém Flusser).

The Media-Philosophical Perspective

The media-philosophical treatment of the time-medium connection, the discussion of dependencies and fundamental changes in time experience, and the ideas of time that build on these, converge (also in authors) in part with the preceding perspectives and findings, but in part they also compete with these. In methodical and systematic respects, three media-philosophical approaches can be distinguished above all. It is true of all these media-philosophical approaches that they also pose the question of mediality in a broad frame of reference and thus develop the subject of time at a problem level that is to be respectively specified.

1. One media-philosophical approach that is much discussed and widespread, above all in Europe, operates with fundamental assumptions about the philosophy of history and tends to teleologize media-historical changes (cf., Jean Baudrillard, Paul Virilio, Vilém Flusser). Modern and postmodern experiences of time play a prominent role in this context. Starting with the basic assumption about the philosophy of history that the historical processes aiming at progress and humanity (in the spirit of Enlightenment and modernity) are being dissolved, the focus for culture-critical and time-diagnostic purposes is above all on the experiences of time that speak for a negative eschatology. Here again the phenomenon of acceleration affecting all areas of life is to be mentioned in particular. In this perspective too, acceleration does not prove to be a desirable effect in reaching certain ends (e.g., acceleration of information exchange up to the speed of light) but is regarded as the signature of an overall cultural process in which the realization of human ends is structurally undermined by excessive acceleration. In conscious contrast to the assumption that a media age might bring about a free exchange of information conducive to the project of a humane world (McLuhan), here the thesis is advocated that information is obliterated by the accelerating speed of information transmission and by the excess of information in electronic media. Paul Virilio puts it pithily in an interview: “In contrast to what we are told, information in real time is not real information, but an action—like a slap in the face.”

2. The second media-philosophical approach operates meta-theoretically and with conceptual criticism—in a highly cross-disciplinary perspective—analyzing the scope and coherence of media-studies theories and theses. Related to the problem of time, the central question is whether one can really infer fundamentally altered concepts of time from the media-determined development of new ideas of time. What is discussed above all are the facts that (a) time is a freely available and manipulable representational parameter, and (b) the respectively generated media reality depends on speed conditions (at the representational level or at the reception level). This approach challenges attempts to understand technical innovations and experiences of time that are in part interpreted as revolutionary (and the undoubtedly linked social changes gradually taking shape in the context of action of the Internet and cyberspace)—as the basis for a “revolution” in the time concept.

Against such attempts (which mostly go along with the thesis of a medium a priori) it should initially be objected, with a *transcendental argument,* that precisely the diagnosis of new experiences of time presupposes, and precisely does not dissolve, a relatively stable concept of time (i.e., a complex of certain categorical distinctions such as before/after, succession/simultaneity, etc.) in order to be able to register variations or changes in ideas of time. That is, as suggested, not an objection to the specifics of a media reality in which time is a freely available representational parameter leading to certain ideas of reality—in part independently of the sequence of events actually observed. Thus with TV weather forecasts, for instance, the (future) movement of weather fronts is calculated and visually simulated on the foundation of a certain data basis. The future's being visually brought to mind by simulating a complete sequence of events is a phenomenon that is just as everyday as it is interesting for the theory of science. It is, however, not yet any indication of a fundamentally altered consciousness of time.

Alongside the transcendental argument, a *genealogical or evolutionary argument* should also be asserted from a media-philosophical perspective. The assumption of a respectively media-determined, uniquely new time consciousness gets caught up in inconsistencies when it is supposed to explain transitions from one paradigm medium to the next. Only in a genealogical and evolutionary consideration (i.e., one incorporating both biological and cultural developments) does the origin become explicable of the foundation of cognitive abilities that are built on by the ideas of time that are respectively varied or extended by technological conditions. And only in this way can it be made plausible why, despite epochal changes in media history, we are quite able to understand past representations and time experiences—which on the assumption of strict epochal breaks would remain an explanatory gap.

In the framework of a *topological analysis,* in which media-theoretical theses are discussed in comparison with results from other disciplines and examined with regard to their coherence, it must further be pointed out that our media practice has until now not significantly changed anything about evolutionary and neurally based timescales of our time window. (Neurologically speaking, perception of the present spans only about three seconds.) The assumption that media-generated time windows, or experience of the simultaneity of remote events, directly correspond to our neurologically based time window should be corrected to the extent that the concern here can be only with a structural analogy. (Also, so far it has yet to be clarified what exactly the relata—media and mental processes—are and how they are connected). In media-philosophical terms, one cannot speak of a simply quantitative extension of the time field but of qualitatively, not quantitively, extended time windows having become possible within an evolved timescale. The comparative temporality of media (cf., primacy of the present), the extension of the present (the tendency to blank out the past dimension, and the time inherent to events before their media processing) is not to be equated with a basic change in our perception of time. "Extension of the present" means more precisely "conceptual extension of the present with relatively constant perception of time."

3. The third media-philosophical approach differs from the preceding ones—the (1) culture-critical and (2) concept-theoretical approaches—in not understanding the concept of mediality in terms of the sender-receiver model. The foundation is a deep-set (quasi-metaphysical) understanding of mediality that accentuates the significance of the "in between." The guiding conviction in this is that the structure of mediality is to be considered as an interval structure, which cannot be reduced to the structures of subjectivity or intersubjectivity, but which rather precedes these. This conviction has been developed through engagement with the tradition of phenomenology (Husserl) and structuralism (Ferdinand de Saussure), particularly in postmodern French philosophy (Jacques Derrida, Gilles Deleuze, Jean-François Lyotard). In the context of this—altogether nonanthropocentric—concept of mediality, time is a key theorem: Time is here conceived as a dynamic structure that cannot be reduced to the sphere of cognitive competences, subjectively available parameters, or the communicative exchange of information.

This conception of time was most radically advocated by Derrida, who characterized media dynamics as "dead time" (*De la Grammatologie*), as distinct from the (metaphysical and phenomenological) paradigms of subjectivity. Following on from this, many attempts have been made to comprehend time completely in terms of the underlying technologies (i.e., those underlying information processes; cf., Friedrich Kittler), which leads, however, to the inconsistencies of media-aprioristic approaches mentioned above. On the other hand, however, attempts have also been made to deploy this altered conception of time for the ontology of individual media without relapsing into a media a priori. Deleuze has carried this out in exemplary fashion for the medium of film by classifying the semantic potential of film on the basis of differentiating subject-dependent (or subject-centered) representations of time and subject-independent representations of "time itself." In so doing, he has created a thesis that the medium of film is particularly suited to the representation of temporal processes. Using the history of author cinema, he has drawn attention to a transformation in the direction of those temporal processes that are no longer to be comprehended via subject-centered conceptions of time.

An Outlook: Time and Media in the 21st Century

It is difficult to deny that experiences of time and ideas of time stand in a close connection with media and media practice. Yet the thesis that time must be specified using different media, and time concepts correspondingly revolutionized, is today—at the start of the 21st century—just as unconvincing as was the thesis that electricity must be differentiated into types of electricity according to the underlying substances (so that there might be, for example, a specific "resin electricity") at the beginning of the 19th century. Time is not a function of media technology. Nonetheless it is true that experiences of time vary, in part considerably, according to which media practice is individually or socially dominant. To put it in the way the social psychologist and cultural historian Robert Levine—who in view of culturally differing rules of social time talks of the "language of time" having different "accents"—does, the language of time also has different idioms and accents in the history of media. But different idioms are not yet different languages. Epochal misunderstandings are likely, but the ability to understand remains fundamentally possible even with a change in media paradigms.

Since the end of the 20th century—that is, since the introduction of the Internet and the development and use of computer animations, simulators, digital movement control, and cyberspace—and increasingly with the beginning of the 21st century, new experiences of time have been taking shape that have not been empirically researched much so far. In connection with the aspects already mentioned (cf., above all the primacy of the present discussed above), the idea of virtual time presents a particular theoretical challenge. This idea is linked with the suspicion of a problematic development. For in the context of digital media, the idea of virtual time seems to be establishing itself as dominant, both in the private realm (e.g., with PC gamers) and in the socioeconomic realm (in the "global player's" field of activity), at the cost of the idea of the time of real developments or a (biographical or sociopolitical) historical time. The much-discussed media-determined loss of reality here exhibits its time-theoretical implications: Virtual time seems to contain the loss of historical time.

Virtual time means here not so much that time is a freely disposable representational parameter but rather that time is an ordering of available events. That is, the idea of virtual time is marked by the image of events being located in a possibility space and standing freely at one's disposal. Here events do not stand under the dictate of irreversibility but are considered in the mode of "as if" and are, according to the aim, reversible. An example of this is the "different lives" in computer games. When your own figure in the game fails ("dies"), the game doesn't end; you simply don't yet reach the next level. To begin with, then, an event within virtual time has quite different consequences for your own actions to an analogous event in real time. That is, in the extreme case, where no more action is normally possible and everything is finished, in virtual time everything can start again anew.

The flipside of such media practice is that actions within virtual time can come at the cost of actions in real time. One should not only think here of the mostly young, intensive player of online games with an endless format, whose gaming passion leads him to neglect to attend sufficiently to his "real" life. Rather one should also think of possibilities for media actions of a global player who pursues abstract profit intentions, largely unburdened by local political or social circumstances, and must pay hardly any or no attention to the "real" life of a company or a social group on the ground. The specific profit intentions lead to a strategic set of actions that is guided by a complex play of information in a global framework. Thanks to the media networking of the world, the global player acts in an endless field of options (i.e., one not limited by local conditions) in which partial failure can be compensated for, or even itself transformed into elements of a win-win situation, by strategic turns. One of the problematic consequences of the action space created by media detachment, or the entry into virtual time, is a peculiar dissonance. The actions made possible by media (in the case of the global player, the global connection of information flows largely independent of local circumstances; in the case of the online gamer, submergence in a virtual world and an attractive role independent of the gamer's own social role or physical constitution) adhere to a different timescale and a different future, one less rooted in the past, than actions in real time.

The tensions between actions in virtual and real time are thus also structurally determined. One of the chronopolitical tasks for the 21st century is to bring geopolitically differentiated, local timescales on the one hand and global connections (of economic processes) made possible by media on the other into a balanced relationship. Admittedly no media-philosophical solution to this problem is to be anticipated; rather it should be recalled what the examples already show: Media-based virtual time and the complex structure of real time are not two spheres that are completely independent of each other. They are conceptually linked with each other (for the virtual time of media practice can only be comprehended in contrast to certain aspects of real time, with some aspects of real time being retained, others suspended) and factually connected with each other (an action in virtual time—e.g., "occupying and defending a country"—is always a certain action in real time too—e.g., "sitting at the computer").

Experiences at the beginning of this century have in the meantime shown that the entry into virtual time (reversible events) made possible by media does not have to mean an exit from real time (irreversible events) but is embedded in contexts of action in which different transitions in both directions and countless functional connections are to be registered. Thus in the realm of online games, it can be observed that the media practice of casual gamers or users of online forums (chat rooms) by no means have to lead to the oft-attested losses of reality. Actions in virtual time often function only as normal moments of relaxation in everyday working life; sometimes they even provide possibilities to try out communicatively and to form one's own identity beyond the often restrictive local conditions. That is, entry into virtual time does not have to come at the cost of time for individual development but can even benefit this. In addition, the media practice of intensive players ("heavy gamers"), for instance, shows that the entry into virtual time is by no means always completely detached from and unburdened by real economic processes.

That entry into virtual time also costs real time is a factor that is meanwhile represented within games in the form of certain advantages in the game and that leads to virtual time and real time standing in an economic relationship to one another that is no longer hidden. Players who lack the real time to work for the desired game advantages (the attainment of which is time-intensive) can nonetheless acquire these advantages by buying these from other players who have invested enough real time to work for the advantages (at the level of virtual time).

However one evaluates these different relations (and in view of some morally and politically problematic developments, one will not want to endorse them in every respect), in any case they show that theories are fundamentally too shortsighted that on the one hand reduce media-determined experiences of time to the logic of the underlying media technologies and on the other hand want to capture the specificity of these experiences of time with strict conceptual oppositions. The undeniable connection between time and media cannot be explained through simple certainties but only by starting with sufficiently complex descriptions of the respective media practice.

MEDICINE, HISTORY OF

Medicine is as old as civilization itself; humankind has always made attempts to heal, cure, and prolong life. Even in the nascent phases of our development, our hominid ancestors recognized disease and sickness, and they made attempts to combat this with what was available at that time, mostly herbs and rituals. In our current phase of evolution, technology and applied intelligence have improved our understanding of what disease, sickness, and even death actually are. Now with the completion of the Human Genome Project and the possibility of genetically tailored treatments, an unprecedented chapter in medicine is about to begin. This entry provides a brief account of medicine's evolution and speculates on its future direction.

Primitive, Ancient, and Modern Medicine

The word *medicine* is derived from the Latin word *medicus,* meaning "physician," and the feminine declension *medicinus,* which means "of a doctor." However, the actual definition of what medicine *is* has changed as our civilization itself has developed through time.

Medicine in its primitive form could be defined as a *ritual* practice, sometimes involving a sacred object that a society believes capable of controlling natural or supernatural powers that act as a form of prevention or remedy for physical ailments. This could involve the use of herbs, potions, prayers, or incantations and was usually performed by a specialized member of a society—a shaman or medicine man. These individuals held special status in their societies for their apparent ability to heal. It should also be noted that even though herbs and potions may have been believed to have supernatural effects by those giving and taking them, some of these herbs and potions did have potent pharmacological effects that were not understood as such until the modern era.

Evidence of prehistoric surgical procedures has been found, most notably for trepanation, a process in which a hole is drilled into the skull, evidently for therapeutic purposes. Trepanation is believed to be one of the oldest invasive surgical procedures, and without any doubt it is one of the first neurosurgical procedures. Evidence on prehistoric human skulls and in cave paintings of the Neolithic era (8500 BCE) establishes that this procedure was in fact practiced widely, most likely with the intent to cure aliments such as headaches, seizures, and possibly psychiatric disorders.

Some of the first evidence of ancient medical information and texts can be found in ancient Egypt in the so-called Edwin Smith papyrus, which has been dated to around 3000 BCE. This scroll is also believed to be one of the first ancient textbooks that illustrates in detail the examination, diagnosis, treatment, and prognosis of a large number of physical ailments. There is evidence of what are believed to be the first surgeries performed in manuscripts from 2750 BCE (250 years after the Edwin Smith papyrus is dated).

In ancient Greece and in early Europe, a natural system of medicine was devised that was called *humoral medicine.* Hippocrates is often credited with innovating this system, but it was actually derived from Pythagoras's idea of humoral medicine, which was based on the treatment of a patient by balancing what were called the four humors: blood, phlegm, black bile, and yellow bile. An imbalance in any of these four humors is what was believed to cause physical ailments. (Pythagoras's four humors were influenced in turn by Empedocles's "four elements.")

A modern definition of medicine is that it is an objective *science* of diagnosing, treating, and in some cases preventing disease and other insults to the body or mind. This type of science implements treatments with pharmacological drugs, diet, exercise, and other surgical and nonsurgical interventions. These therapeutic interventions are performed by a specialized member of society who has extensive education and training. In addition, modern medicine is now based increasingly on scientific evidence and clinical trials, or what is presently called "evidence-based medicine." More specifically, according to the definition provided by the Centre for Evidence-Based Medicine in 1996, evidence-based medicine is the conscientious, explicit, and judicious use of current evidence in making decisions about the care of individual patients.

Comparing and Contrasting Primitive and Modern Healers

There are several similarities between primitive medicine and modern medicine. First, the healers themselves share many similarities. They are in all accounts possessors of some form of specialized knowledge, be it of the spirit world or of anatomy and physiology. In order to perform healing, they all have to undergo some form of training or rite of passage that entitles them to special recognition within their society as a person who can heal. In the past, it was an apprenticeship or a ritual. Today there are formal study, graduations, clinical training, and certifications. In addition, healers hold a high status in their respective societies and command special recognition for what they do.

Second, healers, primitive and modern, have a similarity in their methods of healing, and that is the administration of medicines. Even though the actual types of medication given by the healers differ drastically, the intention is the same, which is to put something external into the body to elicit an improvement of physical symptoms. The universal expectation among patients, primitive or modern, is that the healer "make the pain go away."

Third, healers of any era must inspire the patients' belief. Modern physicians understand that patients' belief that the doctor can help them get well is a large part of successful treatment. The patient needs to have confidence in the physician's knowledge of medicine and experience of practicing it successfully. For ancient medicine as well, the patient had to believe that the shaman's connection with the spirit world was real and that the rituals and herbs would cure aliments.

Healers and Their Methods: Then and Now

Although ancient medicine and modern medicine are separated by thousands of years and have become very different in how they are practiced, another notable similarity is that, as previously mentioned, the function of healing and curing is and was performed by a specialized member of society; not just anyone could do it.

Evidence of shamanism has been dated back to the Neolithic period (8500 BCE), which would predate all organized religions. Presently, some forms and remnants of shamanism are still seen in some societies in Africa and South America. It is also seen in regions of Asia such as Korea, the Ryukyu Islands, and sparsely populated rural areas in Japan.

Many disciplines define a shaman and his function, in a basic sense, as an intermediate between the physical (or what is call the natural) world and the nonphysical realm (or what is sometimes referred to as the spirit world). It was believed that the shaman had the ability to travel between these two worlds and was able to commune with spirits and ancestors to assist them in the healing (or in some cases the harming) of another person. Essentially, the core of shamanism is based on the belief that the physical world is somehow interconnected with the nonphysical world and that the nonphysical world can have a profound effect on the physical world.

Contemporary physicians have long since been divested of their powers of enchantment and connection with the spirit world. They are equipped instead with scientific knowledge of disease and disorders of the human body, and they have access to a vast body of medical knowledge and research. They also have the benefits of modern technology, such as diagnostic imaging and laboratory tests, and thousands of pharmacological agents to choose from. Along with primary and family care physicians who treat a wide variety of general conditions, there are more specialized physicians who treat one specific bodily system or one type of disease or disorder—for example, cardiologists, dermatologists, and psychiatrists.

Medieval Physicians

In medieval Europe, a typical physician was neither well versed in the rituals of the spirit world nor educated in topics such as pharmacology or physiology. Rather, he studied humoral medicine, alchemy, astronomy, and dogmatic textbooks that were sometimes centuries old. These were his tools for diagnosing and treating patients, mostly on the basis of conjecture. Historically the medieval physician did very little to cure rampant outbreaks of diseases or plagues. In fact, most were unwilling to actually touch their patients for an examination. The transitional period between the medieval era and the Renaissance was the time of Paracelsus (1493–1541), who has been credited with pioneering the use of chemicals and minerals to treat sickness. He believed that the human body (and nature) should be studied and understood and that alchemy, whatever its purported ability to make gold and silver from base metals, was unsuited as a tool for medicine.

Sickness: Then and Now

How did our earliest ancestors view sickness and disease? Primitive humans would most likely have perceived sickness and disease as something unnatural or even as a supernatural event. Lacking knowledge of infectious diseases or microorganisms, sick persons could be perceived as being adversely affected by the spirit world or a curse, because they were being affected by something that was invisible or poorly understood. Therefore, only an individual capable of communicating with, and able to influence, the spirit world could abate these supernatural events and thus heal.

In mainstream Western culture today, when someone becomes sick, it now automatically comes to mind that "she has a virus" or "he needs an antibiotic for his infection." No longer do most people blame evil spirits or retribution from the spirit world for illness. Spells, curses, and the "evil eye" have been discounted as causes of illness; the average person today has a better understanding of what "being sick" is and what can be done to cure various aliments.

Pharmacology: From Plants to Human-Made Pharmaceuticals

A change has taken place in *what* is used to cure illness and disease. Early humans had to be very resourceful and use what was abundant and available to them at the time, mostly plants. Today, medical botany or herbalism, the use of plants and plant extracts to cure and heal aliments, has largely been supplanted by modern pharmacology, and most drugs are now manufactured in high-tech laboratories. They are distributed in exact doses, taken for prescribed periods of time, and have extensively studied effects.

In 1960, a Neanderthal skeleton (determined to be over 60,000 years old) was uncovered from a burial site in what is known today as the Shanidar Cave (in Iraq). This specimen was buried with eight species of plants that are believed by medical anthropologists to be used medicinally all over the world. However, the earliest record of the use of plants for medicinal purposes is found in paintings in the Lascaux Cave in France, which have been dated to between 13,000 and 25,000 BCE.

It is believed that early tribal societies eventually created a small semireliable repertoire of medical knowledge based on generations of trial and error experience. The observed effects of specific plants and herbal preparations were transmitted from generation to generation and used therapeutically by a specialized member of society. Ancient societies and early European physicians would use potions and tinctures to treat patients, although they lacked the knowledge of what these potions were doing in a pharmacological or physiological sense.

Penicillin, a byproduct of a fungus, was one of the first antibiotics discovered and used therapeutically. Originally noted by a French medical student, Ernest Duchesne, in 1896, it was rediscovered by Alexander Fleming in 1928. However, the internal use of penicillin as an antibiotic did not begin until the 1940s. Since that time, thousands of medications and hundreds of classes of medications, from blood pressure medication to antidepressants, have been manufactured and administered to patients.

Eventually, with the continued growth and application of knowledge gained from the Human Genome Project, medications may be developed that are genetically tailored for optimum effectiveness with a given patient's genetic makeup. With further research, some genetic diseases will be treated directly by genetic therapies, that is, by actual alteration or manipulations of the genome. It is believed that this will improve the efficacy of treatments and reduce side effects and adverse reactions. The treatment of a patient with therapeutics engineered to correct underlying genetic causes is call "gene therapy" or "genetic medicine." The concept of genetic medicine will challenge the manner in which modern medicine treats life-threatening illness such as cancer, which currently utilizes the surgical extraction of tumors, radiation treatments, and chemotherapy. Our current approach to treating cancer with chemotherapy and radiation inevitably involves some toxic effects for the patient as physicians attempt to localize these effects to the actual cancer.

Modern medicine, despite some shortcomings, has provided our present-day population with several tremendous benefits. With the advent of new medications, treatments, and vaccines, people are now living longer and more productive lives. In fact, global life expectancy has increased from about 37 years in the year 1800 to 67 years in the year 2000, for a global average increase of 40 years.

Medicine in the Future

As medicine has developed from rituals, through alchemy and astrology, to modern technology and to the possibility of genetically tailored treatments, one fact has remained and will remain consistent: The human body becomes ill, breaks down, and dying and death continue to occur. Given humankind's desire to prolong life, the human body will always need healing, repair, and medical treatment by specialists.

The future prospect of space travel suggests the possibility of encountering new forms of diseases and ailments as a result of exposure to the outer space environment. This new environment could also put us into contact with alien microorganisms that could cause different types of illnesses. In addition, space travelers may need to be placed in hibernation for long journeys, and muscle strength would need to be maintained in zero gravity conditions. All of these possibilities would open up a new area of space-travel medicine, a new specialty that would deal with these unprecedented medical problems.

MELLOR, DAVID HUGH (1938–)

David Hugh Mellor, emeritus professor of philosophy at the University of Cambridge, is known for his important contributions to metaphysics, philosophy of science, and philosophy of the mind, with studies, for example, on probability, time, causation, properties, and decision theory. His work stands in the Cambridge tradition of F. P. Ramsey and Richard Braithwaite, in whose honor he has edited anthologies and the works of Ramsey. Mellor's philosophy of time profits from this broad field of interest and combines them systematically; he is one of the advocates of the "new tenseless theory of time."

Two important theories of the early 20th century have influenced Mellor and, as he claims, the whole modern theory of time: McTaggart's A- and B-series theory of time (1908) and Einstein's special theory of relativity, published in 1905. Agreeing with McTaggart's argument against the reality of the dynamic, tensed view of time, Mellor adopts a theory of time based on the B series, which acknowledges only the static scale of the B series as fundamental for any concept of time. In contrast to McTaggart, Mellor does not conclude that time is unreal. He shows that the concept of spacetime as it is presented in the special theory of relativity does not spatialize time. In fact time differs from space in this concept, and that becomes obvious in the formalization of the theory. Time is therefore a problem in its own right. Mellor's position can be characterized as a B series of time that argues for the reality of time—more precisely: time as the causal dimension of spacetime.

A and B Series of Time Differentiated

The first step on the way to Mellor's theory of time is the differentiation between the A and B series of time established by McTaggart. The A series orders facts in relation to the present moment as past, present, or future. Their relation to each other does not change, but their qualification as past, present, or future changes with the flow of time. The B series orders facts or events only with respect to their successive occurrence, no matter which of them is the present one. Therefore it does not need the concept of a flowing time. In everyday language, facts involving time are usually expressed in A sentences; that is, by using tensed verbs. Mellor argues that all tensed propositions or beliefs have B facts as their truth conditions. The crucial question is what makes tensed sentences, or A sentences like "Peter arrived yesterday," true.

Mellor's answer to this question in general is the following: A sentences have B facts as their truth condition. That means they depend, first, on facts like the time when the sentence is uttered and, second, on whether the event that is mentioned really occurred at the time that the sentence says it did. Both conditions can be expressed in B terms as follows: (1) The sentence was uttered on March 2nd, and Peter arrived on March 1st; (2) Peter really arrived on March 1st. If both conditions obtain, the A sentence is true. If the truthmakers were A facts, they would cause contradictions, because the fact that Peter arrived yesterday would have to obtain in order to make the statement true if uttered on March 2nd and not obtain to make it false when uttered on March 3rd. The central thought in Mellor's B theory is that A sentences need B truthmakers in order not to fall prey to contradictions. He does not want to do away with the way of expressing subjective perspectives of time in A sentences. On the contrary, he recognizes the necessity of A sentences and A beliefs within a concept of agency.

As agents, Mellor explains, we depend on our A beliefs existentially. A true A belief at the right time is needed for an action to succeed. But, first, A beliefs are necessary to cause an agent to act. I need the belief that my train arrives at 2 o'clock, for instance, to cause me to leave the house by 1:30. For the success of this action, my catching the 2 o'clock train, the belief that the train arrives at 2 o'clock must be true. Again, the condition for this truth is not the A fact of it now being 2 o'clock, but the B fact that the train arrives at 2 o'clock. The function of A beliefs is to cause agents to act. Therefore A beliefs are indispensable. Beliefs about what is happening now are needed for any action.

Mellor states that the conviction that what is perceived is also present is not grounded in facts but in pragmatic beliefs. The presence of a perception is usually confused with the alleged presence of the object. This plays no role in everyday life, because the time light needs to travel from most objects to the eye and the time needed to process the information is negligible; in the case of cosmologic events, however, the events we perceive now may have happened millions of years ago. On the one hand, the fact remains that there is no presence in the strict physical sense of the word; on the other hand, as species we would never have survived if we had not taken the prey just seen or perceived the predators following us as present. So it is pragmatic and existentially necessary to have A beliefs.

Mellor explains this necessity in terms of evolution: It was necessary for the survival of humanity and even animals to have such A beliefs. Furthermore he thinks that having an A belief is more basic than having a language. It is not necessary to be able to express an A belief or to have a concept of the self or the present for acting on such a belief. The range of A beliefs is not limited to sentences about time. All subjective perspectives, all beliefs about time, place, and the subjective situation belong to its range. A beliefs are subject-relative, which means they belong to the subject that has them in order to cause it to act: "I" have to believe something at the present moment "now" in order to act. No one would act on someone else's belief or on the belief in true B sentences alone.

Besides granting A beliefs a pragmatic necessity, Mellor also says that A sentences have different meanings from their B analogues and therefore cannot be replaced by B sentences. Although A sentences and their B analogues have the same content according to Mellor, they have a different character, because their relation to their truth conditions differs. While a B sentence, for example, "It is raining at *t* (let *t* be the exact time)" is always true (if and only if it rained at *t*); the A sentence "It is raining now" will only be true if said at the time *t;* if said before or after *t,* it may be false. This is the reason why Mellor says that A sentences "mean the functions from any *B*-time to their *B*-truth-conditions at *t.*" In other words: The truth of an A sentence depends on the position of its token on the B scale of time (when it is uttered) in relation to the B-scale position of its content, the event or fact expressed in the A sentence.

The fact that A sentences constantly change their truth values is crucial for Mellor's version of a B theory of time. Their constant change is caused by the constant change of our A beliefs, which determine our perception or understanding of time. A beliefs about what is now change nearly every moment, and their spatial analogues about what is here change similarly. Through the constant change of A beliefs, Mellor explains how the impression of flowing time arises. Despite the fact that the flow of time does not exist as a property of time itself, it is a psychological truth. The phenomenon of flowing time is a mere construction of our minds, which are constantly concerned with changing A beliefs. It is important to stress the point that the psychological and dynamic character of A beliefs does not invalidate them in their function. According to Mellor, these subjective beliefs, or at least some of them, are also fundamental to a concept of the self, even though they do not deserve such a concept to function as a cause of agency. The concept of the self is a second-order belief. A beliefs belong to the first-order beliefs that make us eat if we perceive food; no concept of self is needed for this belief to cause an action, according to Mellor.

Mellor's tenseless theory of time explains how subjective sentences involving time can be made true by nonsubjective truthmakers. It becomes obvious that he acknowledges the tensed view of time as essential only for time-consciousness and in a pragmatic perspective, but from that he does not infer an ontological relevance of the A series. Only the static B series is of ontological relevance. In order to strengthen the ontological argument, Mellor raises the question of what time is. This question entails, among others, the problems of the difference between time and space and of time as the dimension of change, as well as the question of causation.

Time and Space Contrasted

In fact, if time should be a subject of ontology, then it must not be reducible to something else. In special relativity it could seem as if time had been identified with space. Mellor attempts to show that this is not the case. Even though time resembles space in more than one way, it is not the same thing. The four dimensions of spacetime seem to be treated quite equally, because both space and time are systems of order, and time can be represented as a dimension just like space—the three dimensions of space are combined with the one dimension of time. Nevertheless they are not equal. Mellor explains that a difference between spacelike and timelike separations of events or entities is made in special relativity. The three dimensions of space represent an array of possible ways by which things can be in contact, interact, or fail to do so. The dimension of time has basically the same function, but, in contrast to space, things in time can fail to be in contact although they are in the same place, because they are there at different times, or in different words, it is possible for two things or events to occupy exactly the same place, because they can do it at different times. These kinds of separations are called timelike separations. They are treated differently from spacelike ones. This can be shown in the mathematical formalization of distances in spacetime:

The spacetime separation has a positive sign if it represents a spacelike separation and a negative one if it represents a timelike one. Therefore time differs from space in special relativity.

In the next step, time is described as the dimension of change, which leads to the definition of time as the causal dimension of spacetime. Time defined this way is marked off from space not only in terms of formalization but also by nature. McTaggart characterizes time as the dimension of change. Mellor seeks to defend this view without sharing McTaggart's opinion that the A series, which had just been shown as containing contradictions, is fundamental. Taking the A series as fundamental for change would lead to contradiction in the concept of change.

Mellor wants to give an account of change from the B theory's point of view and in respect to special theory of relativity. The first question that arises here is, What is change? The answer Mellor gives is the following: A thing has undergone a change when it possesses incompatible properties at different times; change is a variation over time in the properties of a thing or an entity. This definition excludes various events that might in general be called changes but that do not meet the conditions of the definition: Mellor claims that spatial variation cannot be called change, because the properties that are subject to change have to be intrinsic, not relational. Changes in relational properties are not changes in the thing; they are a variation in its relation to some other thing. Neither spatial variation nor variation in temporal parts or in relational properties can be defined as change, because there is no change in intrinsic properties of the thing. Mellor also states a difference between things and events: Both terms denote particulars, but events, because they are stretched over a certain period of time, consist of temporal parts, while things do not have temporal parts, they are wholly present at more than one time. This is why only things can undergo change in the strict sense of the word, meaning they can possess incompatible intrinsic properties at different times.

McTaggart's restriction of change to the A series was due to the fact that B facts never change; being true at one time means that a B fact is always true. The sentence "It is raining at *t*" will always be true if it really rained at *t*. Facts that change are A facts: that it is raining now might obtain at the present moment and be false a few minutes later because it has stopped raining in the meantime. McTaggart's reason for change relying on the A series is the possibility of continuity. The continuous change of the A series (of the present state to a past one and so on) constitutes the flow of time, and therefore time can be the dimension of change only if the A series exists. Since the A series contains a contradiction, time as the dimension of change does not exist. Mellor does not share McTaggart's conclusion. Although the B series account of change is being criticized for not being able to explain the continuity of change, Mellor attempts to show that indeed it can. If change is described as the possession of incompatible properties at different B times, which entails that every single B fact at its B time does not change, that does not mean that the succession of different B facts cannot be a continuous change. The facts in themselves need not change for change to occur: they only have to follow each other along a causal chain.

Causality

For Mellor, causality is the basic concept that grants time reality. Time differs from space in spacetime, because only in the temporal order are causes and effects necessarily separated. In space, cause and effect can occupy the same place, but they do not occur at the same time. According to Mellor it is not time that fixes the causal order (that would mean accepting the A series), it is causation that gives time its direction: Time order is synonymous with the causal order. Mellor gives several reasons for adopting a causal theory of time order (see Mellor, 2005). In short, his basic assumptions are that (1) causation links only events separated in time, not in space, because causation is never unmediated, and (2) causes always precede their effects. On the basis of these assumptions, a causal theory can explain the differences between past and future as well as the continuity of change. The causal concept of time explains why, according to Mellor, "We can perceive but not affect the past, and affect but not perceive the future" without the necessity to state modal or ontological differences between past, present, and future.

A profound survey of Mellor's approach to the philosophy of time can be found in *Real Time II;* for a concise and informative entry into his thinking, his article "Time" in the *Oxford Handbook of Contemporary Philosophy* is recommended. A deeper understanding concerning the theoretical fundamentals of the definition of time as the causal dimension of spacetime is given by *The Facts of Causation.*

Memory

Memory is the ability to retrieve learned or acquired information. This information can be of previous events, a learned skill, or factual knowledge. Memory is usually distinguished as short-term memory, which is the recollection of recent events, and long-term memory, which is recalling the more distant past. Memory as a biological phenomenon is a record of time.

Ideas and theories about memory have changed in recent decades. Theories regarding memory, much like the theories regarding consciousness, have been profoundly influenced by research in the neurosciences and understanding the functioning of the brain (physiologically and biochemically).

The clinical assessment of memory of the human brain is specified by three categories, which can give insight into the functioning of a person's cognition. First is immediate memory, which functions over a period of seconds. Second is recent memory, which applies over a scale of minutes to days. Third is remote memory, which typically encompasses a period of months to years. These classifications differ only slightly compared with stipulating them as short-term and long-term memory.

Memory can be further classified according to how it is utilized. Working memory is not only classified by the duration of memory retention, but also by the manner in which it is used in daily activities. For example, performing a series of simple calculations would utilize working memory. The actual process of retaining this information (in this case, numbers to be used in a calculation) for short-period use is the working memory, because it is being used at that time. However, working memory is not to be confused with short-term memory, which is memory stored for a short period of time that is not being used functionally.

In addition to classifying memory by the length of time a particular brain is able to retrieve information, it can also be described in terms of implicit (also called procedural) and explicit (also called declarative) memory. Implicit memory is defined as memory that is retrieved automatically, or without conscious involvement. For example, memory for learned skills is claimed to be largely implicit, in that it is automatic. This is in contrast to explicit memory, which requires conscious awareness and intentional recollection to recall. An example of this would be recalling events that took place several years ago, which would require an intentional recollection of that neurological data.

Ivan Pavlov: Early Experiments in Conditioning

Ivan Pavlov (1849–1936) was a psychologist, physiologist, and physician who is well known for his work done in what is known as *classical conditioning*.

Also well known is "Pavlov's dog," a phrase that arose from experiments he performed on dogs. These experiments consisted of producing a stimulus (such as ringing a bell, blowing a whistle, or striking a tuning fork) prior to feeding the dog. This was done repeatedly, and eventually that same stimulus would cause the dogs to salivate even in the absence of food. This process was called *conditioning*.

Early experiments in conditioning were important to the understanding of memory, because the conditioned response relied on the fact that a memory of that stimulus was associated with the presentation of food. Thus, memory is a component of learned behavior.

Human Memory

In establishing an understanding of human memory, four basic elements of memory have been explained: encoding, storage, retrieval, and forgetting. The first element is encoding, the registration of neurological data. This is an active procedure of processing and combining information. For example, while watching a television program, one would see (visual stimulus) and hear (auditory stimulus) information that would be processed by the brain as an event, (e.g., watching the weather report).

The second element is the storage of memory in the brain, which creates a neurological record. Currently, this is understood to take place in three stages: sensory store, short-term store, and long-term store. The sensory store is the perception of the image (e.g., the meteorologist reading the weather forecast), which is thought to last only a split second or just long enough to be perceived by the brain. Short-term store is the storage of this information for only a short period of time, typically only minutes to hours; for example, if someone just entered the room, having missed the weather forecast, and then asked you what it was, your recollection would then be based on short-term store. Long-term store is the storage of that same information hours, days, or years later. The retention of this information for longer periods of time requires rehearsal. In fact, memorization is a method of rehearsal that allows an individual to recall information verbatim.

The third element of memory is the retrieval of memory. This is the recollection of stored information, which is not a random process. In fact, it is an intentional process that is typically in response to a cue, in reaction to a stimulus, or to perform a particular activity. However, it is also thought that memories are reconstructions of the actual event, and these reconstructions can contain errors or inconsistencies in perception when recalled; for example, one might make errors in reporting what the weather forecast was.

The fourth element of memory is forgetting. This is the loss of or the inability to retrieve stored information. There are several theories on forgetting, such as *pseudo-forgetting* (which is held to occur due to ineffective attention in the acquisition phase), and retrieval failure (which is claimed to be an inability to retrieve information at a particular time and, consequently, the inability to be able to recall it at a later time). It is also held that memory loss happens naturally due to decay over time or because of lack of use. Another theory, known as *motivated forgetting,* is an individual's intentional attempt to forget events that are unpleasant or traumatic. This phenomenon was studied extensively by Sigmund Freud (1856–1939); he called these *repressed memories*. He maintained that repressed memories were not lost or forgotten; rather, they were stored in the unconsciousness and are responsible for certain psychiatric conditions that he called *neuroses*.

Long-Term Potentiation

For almost a century, scientists were baffled about how the neurons in the human mammalian brain were able to store memories. In 1973, the first neurological research was published by Timothy Bliss on what he called *long-term potentiation* (LTP), today also known as long-term enhancement. He characterized the phenomena of LTP, which was originally observed by Per Andersen in Oslo, Norway.

While conducting experiments on the hippocampus of rabbits, Timothy Bliss and his colleges discovered that a few seconds of high-frequency electrical stimulation on particular neurons would enhance synaptic transmission in the hippocampus for days and, in some studies, for weeks. This enhanced and prolonged stimulation in the hippocampus was held to be responsible for the formation of short- and long-term memory. Today, researchers of memory concur that the most current evidence supports the role of LTPs in both memory and learning.

Prior to the idea of LTP, the Hebbian theory was the accepted idea of how memory and learning occur. The Hebbian theory was named after neuropsychologist Donald O. Hebb (1904–1985), who stated that the strengthening of the neuronal synapses to one another was primarily responsible for memory and learning. This in part could still be true, and we are learning more about neuroplasticity, which is a process in which the brain changes, or, in this case, strengthens its neuronal connections.

The Neuroanatomy of Memory

Theories about what memories actually are and how memories are actually stored have changed over time. This is mostly due to decades of research in the neurosciences. It is now known that several areas of the brain are required for obtaining, storing, and retrieving memory.

In the human brain, memory is stored and retrieved from what is known as the neural network of the brain. Information from sensory organs travels through specific parts of the brain, is processed, stored, and then able to be recalled at later periods of time. The anatomic regions currently known to be critical to the formation and recollection of memory are the medial temporal lobe, certain diencephalic nuclei, and the basal forebrain.

The medial temporal lobe contains the hippocampus and the amygdala. The hippocampal region is where electrochemical activity converts short-term memory into long-term memory by via LTP. LTP is thought to be a persistent electrochemical increase in synaptic strength following high-frequency stimulation of a chemical synapse.

The amygdala is claimed to rate the emotional importance of a particular experience. For example, a very intense experience, such as pain or pleasure, would create a very strong memory. Conversely, a mild or indifferent stimulus, such as tying a shoelace, may be disregarded altogether and not stored as a lasting memory.

Certain diencephalic nuclei in the dorsal medial nucleus of the thalamus and the mamillary bodies are also involved in memory. This is known because, if these areas are damaged—for example, in thiamine-deficient states or alcohol impairment—then the brain has the inability to recall events. Neurological inactivity in these areas is also noted in Korsakoff's syndrome, a medical condition in which severe impairment is noted in recalling remote memory.

The basal forebrain consists of the basal ganglia and areas called brain-stem nuclei. These structures lie deep inside the brain and consist of the caudate nuclei, lentiform nuclei, portions of the amygdala, and claustrum. Collectively, these areas are involved in voluntary movement and nonmotor learning. It is known that damage to these areas can result in the decline and loss of memory, as well as loss of executive functioning (planning and the ability to pay attention) and loss of ability in set-shifting (the ability to alternate between two or more tasks). This is seen in Parkinson's disease and Huntington's disease.

Neuroplasticity: The Brain Can Change

Neuroplasticity (also known as *cortical plasticity*) is the ability of the brain to form new neuronal connections and to reorganize itself. This can happen in response to certain types of injuries or diseases and in response to new situations and changes in the environment. The concept of neuroplasticity has challenged the previous dogmas that the brain is immutable and that, after a certain age of development, it does not change. Neuroplasticity does allow changes in the brain, and it allows the brain to be incredibly adaptive.

How does neuroplasticity work? In the neuronal network of the brain, each neuron forms several connections with other neurons. Connections that are used infrequently eventually fade away, a process called *synaptic pruning*. Conversely, connections that are used regularly and frequently are strengthened (as proposed by Hebb before there was knowledge of neuroplasticity). In addition to this, neurons can also form new connections to other neurons. It is thought that these new connections are involved in forming long-term memory in response to new information.

It is maintained that the earlier hominid brain was similar to but not as complex as the more modern and evolved *Homo sapiens sapiens* brain. The anatomical and chemical changes in complexity had to have changed over time in order to improve the process of human memory. These changes were in all likelihood induced by natural selection. As our earlier ancestors began to evolve into a hunting and gathering species, an increase in neurological demand was made because of the increased need for communication and the ability to learn and remember more information. In short, an increase in the ability to remember equals an increased chance of survival, and this was provided by neuroplasticity. Neuroplasticity is not exclusive to *Homo sapiens sapiens*. The ability to learn and adapt to new information is apparent in most animals and organisms possessing a nervous system. However, it is not clear how human neuroplasticity differs from the neuroplasticity in other animals.

Virtual Memory

Like the human brain, computers are able to store and retrieve memory called *data*. Early computers used a two-level storage system that consisted of a main memory (RAM), which consisted of magnetic cores, and a secondary (hard disk) memory that was composed of magnetic drums. The problem with this two-level system was that the main memory was very limited, and most programs had to use the much slower hard disk (secondary memory).

In 1959, a one-level storage system known as "virtual memory" was conceived. This new system utilized a special automatic set of hardware and software that kept the majority of the current programs and memory in the faster main memory and, in conjunction with secondary memory, created the illusion of unlimited available memory.

Currently, computers are able to store and retrieve massive amounts of data in seconds, but they need to be programmed to do so. The computer's physical memory is stored using a binary code and can be stored on computer chips, disks, or electromagnetic tapes. This is slightly different from memory storage in the human brain, which is done primarily in the hippocampus using long-term potentiation. The human brain is capable of storing a large amount of memory, but modern computers can store practically unlimited amounts of data with greater accuracy than human memory.

Chimpanzee Memory

Much research has been done on primates, in particular chimpanzees, because of their similarities to humans. The dogma has always been that human executive and cognitive functions are superior to those in the apes. Recently, it was shown in a study done at Kyoto University that young chimpanzees could grasp many numerals at a glance and recall the sequence of these numerals. In most cases, they actually performed at a higher level than mature chimps and humans. This shows that other primates, besides humans, have extraordinary working capabilities for numerical recollection. As with our early human ancestors, this is likely a result of natural selection. Primates with better memory would have an adaptive advantage, and this would increase their chances of survival and reproduction.

Alzheimer's Disease

Several medical conditions that impair memory or cause memory loss have been mentioned already, such as Korsakoff's syndrome, Parkinson's disease, and Huntington's disease. There are several other such conditions including encephalopathy, vascular dementia, stroke, vitamin deficiencies, hypothyroidism, and psychiatric conditions. However, Alzheimer's disease is the most well-known condition that causes memory impairment and loss in humans; this disease is a progressive neurological disorder in which the loss of short-term memory is present in early stages. During the later stages, progressive memory loss will continue, and eventually long-term memory loss takes place.

Much has been learned about the pathology process of Alzheimer's disease. Neurologically, the brain develops extracellular deposits of amyloid-beta protein, intracellular neurofibrillary tangles, and eventually loss of neuron mass. In addition, certain genes have been identified in familial forms of Alzheimer's disease. This suggests that, in the future, perhaps gene therapy may be able to prevent or treat these forms of Alzheimer's disease.

Current treatments can potentially halt the progression of Alzheimer's disease. Medications known as cholinesterase inhibitors have been somewhat effective in treating Alzheimer's patients.

There are also other classes of medications that can help halt the progression of this disease. However, all these medications are very expensive and only slow down the eventual progression of the disease.

Enhancing Memory

Improving or enhancing memory is an interesting topic, because the ability to recall more information accurately and faster would provide an individual with a great advantage. Not having to look up information in a book or journal years after that information has been forgotten would be a tremendous advantage in the work place, pursuing research, completing academic projects, or learning other languages.

No current methods or medications have proven to be 100% effective in improving human memory. Certain didactic methodologies aim at improving the retention of memories (such as facts, words, and diagrams) that can help with learning and scholastics. Herbal medicines like *Gingko biloba* have been shown to improve the circulation in the brain. Proposals have been made that this medicine could, in theory, improve memory, but no conclusive evidence exists as of now. A more complete understanding of the genetics that may be involved in memory could in the future propose the possibility of the genetic enhancement of memory.

It has been well documented that exercise that increases circulation improves memory but does not enhance memory. This is because improved circulation increases oxygenation to the brain. It is also true that a healthy diet gives rise to a healthier brain and thus improved memory. Dietary vitamins, especially B-vitamins and omega-3 fatty acids, are known to maintain healthy memory. Again, maintaining healthy memory does not mean enhancing memory beyond its human capacity.

Our understanding of memory has changed over time, mostly due to neurological discoveries, in particular LTP and neuroplasticity. Likewise, over time, our ability to utilize memory has improved our species' ability to survive. However, human memory is not perfect; neurological information can become distorted, lost, or in some cases repressed. Disease can also degrade the memory process. Continuing biological evolution may gradually result in improvements in human memory. In the shorter term, perhaps our own efforts to understand the neurobiology of memory more completely will lead to future improvements in human memory through new medications or gene therapy.

Merleau-Ponty, Maurice (1908–1961)

Maurice Merleau-Ponty was a French philosopher in the tradition of phenomenology. He taught at the École Normale Supérieure, later held the chair of child psychology and pedagogy at the Sorbonne, and in 1952 became the successor of Louis Lavelle at the Collège de France. In 1946 he founded the journal *Les Temps Modernes* together with Jean-Paul Sartre, but he withdrew his cooperation in 1955 and subsequently left the editorial board.

Merleau-Ponty developed his thoughts under the influence of various schools of thought, the phenomenology of Husserl and Heidegger being the most important; others were dialectics (Hegel, Marx), existentialism (Sartre) and neocriticism

(Brunschvicg). His theory of time is based on the Husserlian phenomenology and is to be found in two of his major large-scale works: the early work *Phenomenology of Perception* (1945) and the unfinished manuscript *The Visible and the Invisible* (1964), which was posthumously published by Claude Lefort.

In the discussion surrounding his work, it remains contentious whether there is any continuity between the early and the late thought or not. Time as subject is treated quite differently in the two works mentioned above: In *Phenomenology of Perception,* Merleau-Ponty analyzes time in a phenomenological manner, and in *The Visible and the Invisible,* in which Merleau-Ponty seeks for a way of thinking beyond subject-object dualism, time becomes a subject of ontology. But already in his early work, Merleau-Ponty argued against the dualism of subject and object and the theoretical concepts of empiricism and idealism, which emphasize a dualistic way of thinking. Although his analysis of time exhibits a tendency toward a subjective notion, it would be a misinterpretation to speak of a subjective view of time. In fact, Merleau-Ponty's concept of time undergoes continuous development throughout his life's work.

In *Phenomenology of Perception,* Merleau-Ponty argues against the idea that time resembles a flowing river. This image of time is problematic from two perspectives: First, it suggests that time has an existence in itself and, therefore, is something in the world; and, second, that time flows from the past to the future or vice versa. Merleau-Ponty denies that time exists in the world; he says that there is no such thing as succession to be found in the world of things. This position has led to the widespread conviction that he defends a subjective view of time. But time is also not to be found in consciousness, according to Merleau-Ponty. The role of the subject is to unfold time, and it does so from the present, which Merleau-Ponty considers to be the source of time. Therefore, there is no flow of time from the past to the future. Moreover the concept of unfolding or constitution of time is not completely subjective, because contact with the world is necessary. Furthermore, this special kind of constitution does not imply a completion—time is never wholly constituted, it remains *in statu nascendi* as Merleau-Ponty calls it. That means it cannot become an object of complete recognition. Merleau-Ponty understands time in *Phenomenology of Perception* as a dynamic structure that constantly evolves from the primordial interaction of subject and world.

The constitution of time is bound to the present, and the reason for this present-centered view of time lies in the function of the body (the *corps propre*). The concept of the body takes over a transcendental function similar to the transcendental consciousness in Husserl's phenomenology: It is the condition of possibility for perception, because it situates the subject in the world and gives it a perspective. Husserl did not think of the body as basis for perception, because he held that the body is a concept that first has to be constituted in experience before it can function as a means of perception. The difference to Husserl's concept is that the transcendental consciousness is itself transcendent. On the contrary, the body has a transcendental function but is not transcendent itself. The body's significance for time lies in its presence for the subject. It is always present for the subject even if the subject has not attained self-consciousness yet. My own body cannot be compared to an ordinary object in the world, because I am not able to distance myself from it in order to perceive it as a whole thing or from all sides. That means my own body is always present for me, but it can never be wholly presented to me. Because the body is fundamental to perception, it also determines the time-consciousness to evolve from the present moment. But the present moment, just like time as a whole, remains *in statu nascendi;* in other words, it is never complete; the present as the source of time is never fully present, because it constantly evolves.

Merleau-Ponty states that time and the subject are identical, in the sense that their structure is alike. The identification of subject and time is programmatic for Merleau-Ponty: It expresses his aim to describe time from the perspective of the subject without limiting it to a subjective concept. Since time and the subject are not heterogeneous to each other, Merleau-Ponty doesn't require a higher-order subjectivity that synthesizes time to make it available for consciousness.

In *The Visible and the Invisible,* Merleau-Ponty's aim is to give phenomenology an ontological foundation. He stresses the notion of time as dimension of being and even speaks of time as an element in the ancient Greek sense. Time is the element in which structure becomes possible, and structure is necessary for the possibility of being; as a dimension of being, it is fundamental to the structure of subject and object. Merleau-Ponty expands the body-concept to the concept of "flesh." He uses this term to denote the irreducible bond of subject and world on the level of corporeality and perceptual structures. Because he connects the notion of flesh with time (the flesh of time), it becomes obvious that here at the latest he no longer defends a subjective view of time (if he ever had done so). The importance of the present has not lost weight. The flesh as universal structure is not restricted to the perceiving subject but contains both the perceived and the perceiver (perception has its place in between subject and object, it is not only an act of the subject); it is a structure of simultaneity. In the presence of the flesh, past, present, and future are contained simultaneously. The present is itself structured, this richer notion of presence is captured in the term *simultaneity.* In this expanded view of time, Merleau-Ponty also reflects on historicity from various, preferably nondualistic, perspectives. An ontology of time from a Merleau-Pontyan perspective will neither objectify it nor restrict it to subjectivity. Although being cannot become objectified, it is open to philosophical interrogation; therefore, Merleau-Ponty himself calls his ontology an indirect one.

Merleau-Ponty's late thoughts about time remained fragmentary and, as such, open to various interpretations. Nevertheless, they are worth considering for a nondualistic time theory. His philosophy influenced among others the works of Foucault and Derrida (for example, his critique of the metaphysics of presence) and is the subject of philosophical discussions in Europe and to a great extent in North America, where for example the relevance of his theory for the interpretation of recent results in the cognitive sciences is discussed.

Metamorphosis, Insect

Metamorphosis is a temporal process of development involving the interaction of hormones triggered at particular stages of growth. Metamorphosis of greater or lesser degree is found in most organisms where there is a developmental transition over time in body form between the egg and adult. Insects undergo a particularly noticeable metamorphosis involving distinct stages of development that often occur in different habitats or utilize different food resources. Developmental transitions occur between different juvenile stages and are terminated when the adult stage is reached.

With a relatively inflexible outer integument or exoskeleton, insect growth is only possible through periodic shedding or molting of cuticle between each instar followed by a rapid expansion of a soft, new cuticle until it hardens. This expansion facilitates further growth during each developmental stage or *instar.* At emergence from the egg, most insects are structurally different from their adult counterparts. This difference may be slight or pronounced. Juvenile stages are usually characterized by feeding, growth, and development of external and internal structures such as wings and reproductive organs that are not fully developed until the final molt into the adult. In many insects metamorphosis is confined to a series of instars during a single season or year for those species with an annual life cycle.

Metamorphosis between instars may be confined to a matter of days in species with rapid life cycles (such as insects feeding on ephemeral fungal fruiting bodies) or spread out over many years in long-lived species with an extended juvenile growth period. There can also be considerable variation within a single species. Juvenile development in the wood-boring ghost moth *Aenetus virescens,* for example, may vary from as little as 9 months between egg and adult to as long as 4 years within a single population. The number of instars is also variable between species, and sometimes within species. Many insects, especially those that develop through their life cycle each season, have relatively few instars, with four to five stages being common.

There are several distinct patterns of insect metamorphosis with contrasting developmental patterns that contribute to the structural diversity of a group of organisms that may otherwise have had a more homogenous appearance. Insects that never evolved wings, where juveniles resemble adults and adults also continue to molt, are called *ametabolous* (or *aptergota* = without wings). This development pattern occurs in five primitive insect orders that include springtails and the common silverfish. Most insect orders are *hemimetabolous* (also called *exopterygota* for their externally visible wing development) with a dimorphic life history divided into a series of nymphs that molt through several instars and adults that do not molt. In these insects, wings develop gradually as external wing pads in the older juveniles, and only the adult has fully functional wings (with the unique exception of mayflies, where the final juvenile instar has fully developed wings). Hemimetabolous insects include grasshoppers and their close relatives, such as stoneflies, and true bugs.

Insects with the most distinctive stages of metamorphosis are *holometabolous,* where there are three main stages of development: larva, a pupa, and adult. In this developmental sequence the larva is structurally and behaviorally different from the adults. Compound eyes are usually absent in the larval and pupal stages (where the eyes are otherwise absent limited to several single lenses). The holometabola are also referred to as *endopterygotes,* because the wings and other features develop internally until the pupal stage, when they become everted and visible externally, although they are not fully expanded to the adult structure. Evolution of holometabolous development is widely regarded as a key evolutionary innovation contributing to the comparatively diverse speciation within 11 orders that compose about 75% of all insect species.

Transitions between different stages during metamorphosis involve a sequential web of interacting genetic and biochemical factors and the balancing effects of hormones that effect molting with those that maintain the juvenile stage (juvenile hormone) by preventing the epidermis from depositing adult cuticle in response to the presence of molting hormone. The specific developmental triggers for the secretion of brain hormone are generally not understood. In some cases, metamorphosis is triggered by internal indicators of body growth, such as stretch receptors that indicate a particular level of body expansion has been reached, or the attainment of a critical body weight.

Molting proceeds through three major complementary processes:

1. Old cuticle is separated from the underlying epidermis, and 80% to 90% of this cuticle is reabsorbed through the action of enzymes while a new cuticle is secreted by the epidermis. This process is initiated by release of prothoracicotropic hormone in the corpora cardiaca (or corpora allata in Lepidoptera) of the brain, and this hormone stimulates production of ecdysome in the prothoracic gland. In turn, ecdysome results in the production of the molecule 20-hydroxyecdysome, which regulates the genes that produce new cuticle.

2. Molting is controlled by release of a molting trigger from the epitracheal glands. This hormone stimulates the brain to produce molting hormone

and behavioral changes in the insect as a prelude to molting. The molting hormone also produces a positive feedback loop between the brain and epitracheal glands resulting in a massive release of molting hormone that in turn results in the release of crustacean cardioactive hormone by the ventral ganglia. This regulates the transition from premolting behavior, such as body movements that help separate the overlying cuticle, and molting behavior, which comprises waves of body contractions that continue until the molt is complete.

3. Following the molt, the body undergoes expansion and hardening of the cuticle. Wing expansion in the new adult is facilitated through abdominal contractions forcing blood into the wings, and this activity also stimulates release of bursicon, which further increases the flexibility of wing cuticle and then initiates hardening of the cuticle.

In holometabolous insects, brain and juvenile hormones are both produced during the immature stages until the last immature instar, when juvenile hormone production is either terminated or decreases below a threshold level where metamorphosis into the pupal and adult stage occurs as adult characteristics are no longer inhibited. The adults of most insects do not molt, because the prothoracic glands degenerate either before or after adult emergence, and there is no longer the secretion of molting hormone. In hemimetabolous insects, the transformation between the immature and adult stages is more gradual. Brain hormone includes a number of steroids that act on genes through a receptor-mediated process that determines which genes are activated at a given time and consequently which enzymes and structural proteins are synthesized.

The transition between instars usually takes place over a few minutes as the old cuticle breaks open along the dorsal midline of the thorax and the insect extrudes is body through this opening, with the appendages such as legs and antennae along with the tracheal tubes being the last to pull away. This process is preceded by a separation of epidermal cells from the old cuticle and the secretion of a new cuticle as well as enzymes that digest 80% to 90% of the old cuticle. The insect pumps air into the body, which expands its volume, resulting in the breakage of old cuticle along the dorsal line. The body is extruded out of this break, and the insect pulls itself away from the old cuticle. This is followed by a period of resting as the new cuticle is hardened. It is during this process that the size of the body is expanded so the new instar is larger than the previous instar. The process of metamorphosis begins with hatching from the egg when all insects are small, sexually immature, and lack wings. As the juvenile and adult stages have often diverged evolutionarily in form and function, the juvenile is more efficient at feeding and growth, while the adult is more specialized with respect to dispersal and reproduction.

The size at which molting occurs is not absolute and depends on the size of the insect at the beginning of the instar. In some species and where food is insufficient, the molt may result in a smaller instar or in the retention of a juvenile stage rather than a subsequent instar such as the pupa. Environmental conditions may also modify the amounts or timing of hormone secretion, and where these factors are predictable components of development, they will result in characteristic differences between individuals composing different castes in social insects. Juvenile honey bees will develop into queen bees when fed a diet based on secretions of the nurse bee's mandibular glands, and they will develop into workers when fed higher proportions of hypopharyngeal gland secretions from worker bees. Ants will develop into minor or major workers or soldiers according to the quantity of food that will result in larger juveniles. These size differences affect the quantity of juvenile hormones, which is higher in the final instars of larvae developing into queen bees or major and soldier ants. In aphids, metamorphosis into the final adult form is affected by day length. Under long photoperiods, the largest embryos will develop into parthenogenetic forms, whereas under short photoperiods the embryos will give rise to sexually reproducing forms. The development of parthenogenetic forms is stimulated by the secretion of hormones from cells in the brain that respond to the amount of light passing directly through the cuticle of the head.

Metanarrative

A metanarrative is a theory of history that is said to move in a specific direction and, on the strength of which, confident predictions about the future can be made. Metanarratives have also been called Grand Narratives, or Master Narratives (usually complete with capital letters) and the philosopher Karl Popper spoke of historicism in the same context. The critical factor in a metanarrative, and what distinguishes it from a historical perspective, is the blending of the historical account into an assertion about how the future will unfold.

Several great systems of thought have articulated, or at least assumed, a historical narrative. Marxism and Christianity, for instance, both involve a metanarrative. For example, Christianity speaks of a creator God who made the world and then placed Adam and Eve in it as the most important products of that Creation. Eve's sin meant the expulsion of them and their progeny from paradise and into the world of sin, suffering, and death. People were then offered a way out of this condition when God sent his only son as savior, so those who believe in his salvific efficacy would be saved from death and live in bliss in heaven for eternity. Eventually history will be brought to a close when, at some time in the future, Jesus Christ returns (the Second Coming) to judge the living and the dead and confer punishments and rewards as appropriate. This is a metanarrative in that the theory of history blends seamlessly into a prediction about the future.

Metanarratives have been around for a long time. Ancient and medieval writers frequently spoke in terms of history being a succession of ages. In 725 CE, the Venerable Bede (673–735 CE) wrote of the ages of man in his *De Temporum Ratione* (*On the Reckoning of Time*). Bede followed the most popular route, thinking in terms of the four ages of man. This goes back to the Pythagorean numerology and to the association of the number four with the four seasons, the four cardinal directions, and the four original elements as outlined in Greek philosophy.

In the 12th century, the idea that human history is in fact punctuated by seven ages became more popular. Unlike the four-ages theory, the seven-ages theory was astrological in origin, working on Ptolemy's seven-planet (including the sun and moon) cosmos. It is most memorably recalled for us now in Shakespeare's *As You Like It* (act II, scene 7).

The extraordinary appeal of Marxism in the 19th and 20th centuries lay in the secular treatment it gave to what was fundamentally a religious metanarrative, with its confident belief that socialism would, in the future, be replaced by communism, which will mean that all material contradictions and inequalities will have been resolved.

Metanarratives found their most enthusiastic critics in postmodernist thinkers. Postmodernism was not so much a coherent philosophical movement as a diffuse mood. It remains influential in some humanities' disciplines but, since the second half of the 1990s, has faded from prominence in most areas. The classic definition of postmodernism was given by the French thinker Jean-François Lyotard as "incredulity toward metanarratives." This seemingly reasonable idea was promptly undermined, however, when Lyotard made it clear he did not mean incredulity at all, but outright opposition. It was also apparent that Lyotard was, if unwittingly, assuming a metanarrative of his own. A few sentences after talking of incredulity, Lyotard spoke of "the obsolescence of the metanarrative apparatus" and the time "after metanarratives."

The postmodernist hostility to metanarratives was expressed even more openly by Patricia Waugh. In her introductory essay to an influential anthology of postmodernist ideas, Waugh went further than Lyotard when she added that postmodernism was about the "abandonment of all metanarratives which could legitimate foundations for truth." More than this, Waugh also declared metanarratives were no longer even desirable. Another influential postmodernist, Zygmunt Bauman, spoke of modernity as a "long march to prison," one that was being undone by the "second Copernican revolution" of postmodernist thought, led by Martin Heidegger. And the most radical postmodernists spoke in terms of modernity having been vanquished and the theories that sustained it destroyed, leaving modernity redundant, never to be brought back. At whichever point they were located along the postmodern spectrum of thought, it appeared that, however much they declared their incredulity toward metanarratives, it seemed postmodernists could not free themselves from them.

Much more effective criticism of metanarratives came from Karl Popper's book *The Poverty of Historicism*. Written in 1935, it was not translated into English until 1957 but quickly established itself as influential after that. The key weakness of historicism, Popper argued, was to equate laws of development with absolute trends, which were arrived at by some metaphysical necessity. The historicist went on, Popper claimed, to want to change the course of history by virtue of superior knowledge of the dialectic of history. But this was to put the cart before the horse. While history needs to be written from a preconceived point of view, Popper wrote, this does not mean the historian's preconceived points of view should be taken as historical laws.

Others have wished to retain a place for metanarratives, even if only for their symbolic power. Some feminist thinkers, for instance, have been fiercely critical of the wish to jettison historical accounts of the progressive emancipation of women from patriarchal oppression. By dismissing such an important struggle as simply an arching tale, these critics suggest, the historical reality of those emancipations is jeopardized.

Metaphysics

Metaphysics is one of the oldest, least explicit, and most controversial disciplines in Western philosophy as far as its evaluation is concerned. There has been no widely accepted definition, nor any strict delimitation of its subject and goal so far. In the last 2,500 years of its history, metaphysics was considered to be a basic philosophical discipline covering the question of "what really exists," or dealing with the first principles of being and cognition of all things. On the other hand, it has been questioned and rejected as a useless and nonsense activity. Thus, all of its history can be seen as a process of continual transformations seeded in the tension between its acceptance and the cyclical recurrence of critiques proclaiming its "crisis," "abolition," "termination," or "death." One of the most significant motives of the critique of metaphysics was metaphysics' prevailing tendency not to fully realize the role of time and temporality in the explanation of the world.

Origin of Name

The term *metaphysics,* handed down to the present, arose accidentally in the 1st century BCE when Andronicus of Rhodes, a peripatetic expositor of Aristotle, summarized his unlabeled treatises under the term *ta meta ta physika,* treatises that in his catalogue follow Aristotle's work *Physics*. Aristotle himself most commonly referred to these teachings as "the first philosophy" (*he prote philosophia*) but also as "wisdom" (*sophia)* or "theology" (*theologiké*). Late Aristotelians, especially Alexander of Aphrodisias in the late 2nd and early 3rd centuries CE, understood Andronicus's classificatory meaning of the word *metaphysics* as matter of content—as a teaching dealing with what is *beyond* the physical world, a teaching about the supersensible, transcendent, and intelligible entities (including God). Also in this sense, Simplicius and Boethius used the one-word term *metaphysica* in the 4th and 6th centuries CE, respectively. European philosophical thinking acquired this understanding of the term during the 13th-century period of scholasticism.

History of Metaphysics

Antiquity

In ancient Greece, the development of metaphysics is connected notably with the names of Parmenides, Plato, Aristotle, and Plotinus. Parmenides (540–450 BCE), by arguing that "being is, and nothing is not because nothing cannot be thought of, and so, the thought and the being are the same" and by his follow-up claim that being is one, continuous, changeless, and eternal, founded a qualitatively new variant of philosophical thinking about reality. His "thinking and being" correspondence principle, as well as his distinction between reality being ultimately true and appearing by sense perception, have become determining, and at the same time, limiting considerations for the entire field of classical metaphysics. Plato (428–348 BCE) elaborated on Parmenides' reflections, and in his middle writing period, he argued for the division of the world into two realms. One was *noumenon*—which exists by reason, and therefore is real, being the perfect world of original, eternal, changeless, and intelligible ideas; and the other was *fainomenon*—the imperfect world of appearances and derived, changeable, perceptibles.

Because metaphysics transcends the perceptible and reaches the top of the hierarchically ordered world of ideas—where the Good dwells as an origin of everything, factual thinking about reality is associated with axiological and at last, epistemological aspects. For metaphysics examines the fundamental principles of specific sciences (mathematics) as well. However, for further development of metaphysics, Plato's distinction of a privileged, timeless world of ideas and a disqualified temporal world of particulars became significant; time is understood there as something that metaphysics should overcome.

Aristotle (384–322 BCE), the founder of metaphysics as an independent philosophical discipline, critically elaborated on his predecessors' initiatives. This became obvious in his tendency to rehabilitate the dynamic world of perceptibles. Time as "a number of movement in respect of the before and after" is the fundamental element of entities to which belong motion and becoming in this context. Considering Aristotle's solution of this problem, as well as his delimitation of metaphysics' subject and goals, the factual legacy of his work remained ambiguous. Notably, his understanding of metaphysics, understood at one point as *ontology* and at another one as *theology,* proved to be historically significant.

In the first case, Aristotle distinguished metaphysics as a universal science about "being" (entity) as being science dealing with being as such, from specific sciences always dealing with a specific kind of being (entity). However, his ontology did not declare being to be one and beyond the diversity of things as Parmenides did. It just gives us an account of the most universal kinds of entities in their plurality—that is *a theory of categories*. Existing means to exist in a certain way, that is, in quite a few differentiations—as substance (e.g., a man), quality (e.g., whiteness), quantity, relation, etc.

However, further inquiries led Aristotle to understand metaphysics as a specific science about an ultimate type of entity, that is to say, substance, which testifies what a thing is and has an important position among categories. In reality, however, there are various types of substances, and the most perfect and dignified is the divine one (the self-thinking, eternal, unmoved first mover). Thus, metaphysics becomes a special kind of substantial ontology—*a theology.* Another definition of metaphysics by Aristotle, as a "knowledge of first causes and principles" of entities, led to a similar conclusion. The most crucial of the four causes—material, formal, efficient, and final—is the last one: Everything is carried out for some purpose, due to some good. And because the highest purpose and good is God, metaphysics, as a study of first principles, is (natural) *theology.* Here, the roots of the idea of unity between ontology and theology, according to Heidegger's so-called ontotheology, are to be found. This idea was later elaborated by scholastic philosophy.

It's worth mentioning that Plato as well as Aristotle did not understand metaphysics as a strictly descriptive contemplation on reality. On one hand, there's an axiological aspect—the cognition of reality is always interconnected with the cognition of the good and the values, and on the other hand, there's an epistemological-logical aspect—categories and principles do not only relate to the reality but to our thinking about it as well.

For Plotinus (204–270), metaphysics is mainly so-called *henology*—a teaching concerning the unthinkable and unspeakable, the not-being and the above-being *One* as the basic principle of all things. Out of this *One,* the entire reality emanates following a degenerative descending process. Even time is only a movable, imperfect picture of the eternal spiritual principle. The aim of philosophy is to free man from empirical plurality and temporality and to unify him with the perfect *One*. Plotinus brought strong elements of mysticism into metaphysics.

Middle Ages

There was an important transformation of metaphysics in the Middle Ages, especially with regard to the scholastic reception of Aristotle's work. Creationistic elaborations of its ontotheological traits, mostly performed by Thomas Aquinas (1225–1274), were of determining importance. For Thomas Aquinas, metaphysics, as a constituent of philosophical wisdom (*sapientia*), is a science about being as to what extent it is being (*ens inquantum ens*); hence it is a science covering the entire reality. However, investigating is not restricted to the perceptible world. It gradually proceeds to examinations into the supersensible (soul, angels) and results in rational contemplation on God. For if metaphysics is to understand being as such, first, being's cause must be understood. And the first cause is God, not only in Aristotelian terms as a *final cause of becoming of things,* but as *a cause and principle of being* of all things created. Metaphysics culminates in (rational) theology as in its ultimate ontology. Thomas Aquinas determines time likewise as Aristotle did, as a measure of changes that arise in bodies in respect of the before and after. It belongs to creature, not to God alone.

For such a concept of metaphysics, it was necessary to provide a rational evidence of God's existence; especially an ontological argument was needed. The argument was put forward by Anselm of Canterbury (1033–1109), who deduced an inevitable fact of God's existence out of the concept (essence) of God, understood as something that is the most perfect (and thus timeless and changeless also) and above which nothing greater can be conceived. Otherwise, there would be controversy. This proof, in its various forms, has become a constituent of great metaphysical systems of modern times.

The problem of universals led to serious consequences for metaphysics in the Middle Ages: Do the contents of universal concepts exist in reality or not? The answer to the dispute, with its prehistory in Plato, the Cynics, and Aristotle, resulted in the birth of *realism* (Anselm of Canterbury; William of Champeaux, 1068–1121) and *nominalism* (J. Roscelin, 1050–1120; Duns Scotus, 1264/1270–1308; William of Ockham, 1290–1349). According to the first, universals exist in reality, before particulars exist and apart from them, and only subsequently they appear in particulars, which are derived from them, or after particulars, in human mind. The opposite standpoint, in its most radical variation, supposes that universals are mere words (*nomina*), claiming that only particulars exist in reality. In its moderate variation, nominalism concedes the existence of universals in human mind (P. Abelard's [1079–1142] *conceptualism*). This controversy has endured, in its various forms, up to the present-day metaphysics, philosophy of logic, and mathematics.

Modern Times

In modern times, the classical understanding of metaphysics as a dogmatic teaching covering the problems of soul, world, and God has undergone significant changes in terms of its understanding, which tends to be more critical. René Descartes (1596–1650) was at the beginning of these critical efforts, and Immanuel Kant (1724–1804) concluded them.

Descartes considered the investigation of the highest principles providing certain knowledge of the world to be the goal of his *philosophia prima.* An epistemological motive, which had been of secondary concern for metaphysics until his time, became fundamental for Descartes. By means of methodological skepticism, he ended up asserting two principles. The first one, *cogito ergo sum,* anchors the certainty of every knowledge of the world not in the world itself, as it worked in the old metaphysics, but through intuitive self-evidence of a reasoning subject (*res cogitans*). This anthropological turn provides background for the second principle, *the existence of a perfect God,* as a source for the verity of the external world (*res extensa*). From these principles, like from roots, all efficient knowledge of humankind should grow (physics, mechanics, medicine, morals).

However, part of Descartes's heritage was *res extensa* (material, incapable of spontaneous motion, axiologically neutral) and *res cogitans* (spiritual, autonomous, evaluating) dualism. Primary, attributive determination of the first one is extension. Time (duration) is only secondary, modally characteristic of unattributive motion (alteration of position). It was especially rationalists who tried to offer an answer to varied forms of *mentioned dualism* (the problem of subject-object relations, mind-body problem, absence of values and dynamics in reality, etc.). For Baruch Spinoza (1632–1677), substance is one, that is, *Deus sive natura,* and metaphysics is identical to ethics. N. de Malebranche (1638–1715) presents an occasional correspondence of both substances through God. According to G. W. Leibniz (1646–1716), there are an infinite number of spiritual, that is, spontaneously dynamic and thinking substances.

Another division of metaphysics emerged in 1562 with the Spanish philosopher B. Pereira (1535–1610), who divided it into general (*metaphysica generalis*) and specific (*metaphysica specialis*). This division was systematically completed by Christian Wolff (1679–1754) in 1730. While general metaphysics (ontology) is a basic philosophical science, rational cosmology, theology, and psychology are disciplines of specific metaphysics.

The Modern Ages empiricists, unlike the rationalists, took quite a rejecting stance on the possibility of metaphysics; they demonstrated the empirical groundlessness of its basic concepts based on the thought/being correspondence. Thus, for John Locke (1632–1704), substance is unconceivable apart from the bundle of its attributes. George Berkeley (1685–1753) denies the existence of the external substance (*res extensa*) and David Hume (1711–1776) denies the existence of both external and internal substance (*res cogitans*) and the concept of causality as well, taking it as a result of everyday habit.

Kant rejected all of the previous "dogmatic" metaphysics as a fictitious knowledge, because by exploring the problems of the soul, world, and God, it applied concepts of pure reason in an inadmissible and transcendent way and beyond the borders of possible experience to a thing-in-itself (*noumenon*), which is unconceivable. Thus, metaphysical reason, not being able even to justify the existence of its subjects, had to cope with insolvable antinomies in all of its domains. As becomes obvious, an ontological proof of God's existence is impossible. Existence is not an attribute and cannot be deduced. The *cogito ergo sum* proposition is a paralogism as well.

Thus traditional subjects of metaphysics do not belong to theoretical reason but, like its postulates (the postulate of freedom, immortality of the soul, the existence of God), to a practical one. However, a new critical metaphysics is possible. It is a transcendental theory that does not pursue the objects themselves, but, provided that such cognition is a priori possible, it pursues our forms of their cognition. It is a study of categories, but these are not perceived as the most universal aspects of things (ontologically) but as a priori forms of data being linked in experience, as a "logic" of experience. It includes also contemplations about time, which according to Kant does not belong to things themselves but is one of two a priori principles of pure intuition (the second one is space) that provide humankind with an inner experience and vicariously an experience of external phenomena.

G. W. F. Hegel (1770–1831) took quite a different stance toward metaphysics. Although he blamed metaphysics for not being dialectical, he accepted and absolutized the thought and being correspondence principle. On its basis, he attempted to offer a dynamic, nondualistic view of reality in his absolute idealism. Within the evolutionary conception of reality, he identified ontology (general metaphysics) with (dialectic) logic. Here he describes the self-contradictory process of the self-realization of the freedom of absolute idea, which is developing from the "in-itself and for-itself" stage (*logics* as the overcoming of rational theology), through the "otherbeing in nature" stage (*philosophy of nature* as the overcoming of rational cosmology), to the stage where idea "recurs back from its otherbeing" (*philosophy of the spirit* as overcoming of rational psychology). The essential medium of this process is time ("intuitive becoming"), in which self-realization of the spirit is realized until is rounded off.

Hegel's influence on 19th-century metaphysics was strong but short-lived. In contrast to Hegel's approach, the majority of 19th-century philosophical movements (positivism, neo-Kantianism, etc.), being under the influence of Hume's and Kant's criticism, rejected classical metaphysics as a theory of reality (scientism, gnoseologism). The implication of this was that similar stances toward metaphysics, though not epistemologically motivated, were taken by Søren Kierkegaard (1813–1855), Karl Marx (1818–1883), and Friedrich Nietzsche (1844–1900).

20th Century

In the 20th century, understanding of metaphysics' subject and goals was considerably influenced by a linguistic turn in philosophy. The attitude of analytic philosophy, as a protagonist of this turn, changed. At its inception (until the 1920s), it offered a criticism of certain type of metaphysics (neo-Hegelian) for the sake of another one (G. E. Moore's [1873–1958] realism, or Bertrand Russell's [1872–1970] logical atomism). Later, in the 1950s and 1960s, under the influence of Ludwig Wittgenstein (1889–1951) and the activities of logical positivism, analytic philosophy became radically antimetaphysical. Following Wittgenstein, who claimed that philosophy is not a theory but a criticism of language, logical positivists including Moritz Schlick (1882–1936) and Rudolf Carnap (1891–1970), who understood philosophy as a logical analysis examining the meaningfulness of the language of science, whereas a criterion for meaningfulness resides in the feasibility of the sentences to be empirically verified (verificationism). Metaphysical sentences are not verifiable and thus are meaningless, because they refer to something above or beyond any experience. They do not account for referential but only for expressive function; they reflect their authors' personal sentiments and view of life.

Since the late 1950s, a renaissance of metaphysics within analytic philosophy has taken place, which was mostly associated with initiatives of Willard van Orman Quine (1908–2000) and P. F. Strawson (1919–2006). Quine recognizes metaphysics (or, to be more exact, ontology) as a reflection on what there is. However, it does not fall under the competence of philosophy (which was supposed to turn into so-called naturalistic epistemology) but belongs to (natural) sciences. This metaphysics concerns especially the so-called ontological commitment—a question as to which entities we are committed to adopt for a theory to be true—and Quine offers a specific criterion. Unlike Quine, Strawson allows for a possibility of an autonomous philosophical metaphysics. It resides in the clarification of the nature and relations between the key—the essential, the most universal and irreducible—concepts, which constitute a structural pattern of human thinking (both ordinary and scientific) about the world. Strawson also makes a distinction between descriptive and revisionist metaphysics. The former, which he prefers, settles for the description of the actual structure of our thinking about the world; the latter is engaged in rendering a better one.

The attitude of the 20th-century nonanalytic philosophy toward metaphysics was critical; however, there were efforts to propose a revised conception. Alfred North Whitehead's (1861–1947) nonsubstantial process philosophy (in which there is the fundamental metaphysical unit—event—well-founded temporally) may be an illustrative case, but the formation of ontologies figures significantly as well—for example, the critical ontology of Nicolai Hartmann (1882–1950) or Edmund Husserl's (1859–1938) eidetic science of intentional objects. One of the most important was Martin Heidegger's (1889–1976) fundamental ontology (elaborating on Husserl's phenomenological method), the aim of which is to manifest temporality as the meaning of being. A later important case was Jean-Paul Sartre's (1905–1980) phenomenological ontology.

An original critical response to the peripeties of this school of thought was provided by E. Lévinas. According to Lévinas, the fundamental weakness of previous metaphysics was that in finding the solution to its crucial question of *the same* and *the other* relation, it always turned into ontology. But ontology is egological and solipsistic in nature—in its efforts to master and usurp the other, it reduces it to itself (the same), canceling its peculiar (unique) otherness and exteriority. Such an identification of the other with the same occurs through the incorporation of a middle element between the two, a representative that the same finds in itself. This has been a universal concept since Socrates, including Berkeley's *individual perception* but also Heidegger's *being,* because Heidegger subordinates the relation toward the other (existing) to the relation toward its being. The path to the other is never direct; transcendence toward it is always embraced by immanence. However, metaphysics is not concerned with representations and thus allows the totalization of the other into the same. On the contrary, metaphysics' main effort is to maintain radical exteriority, the totally other. The transcendence is provided by a face-to-face encounter with the other; another human being and the bond established is thus ethical. Metaphysics as ethics, in this sense, precedes ontology as a philosophy of power and constitutes a philosophy of justice.

Totalizing inclinations within philosophy were again rejected in the last third of the 20th century. However, this occurred not by reinterpreting metaphysics as Lévinas did. It was postmodern philosophers, chiefly Michel Foucault (1926–1984), Jacques Derrida (1930–2004), Gilles Deleuze (1925–1995), Jean-François Lyotard (1924–1998), and Richard Rorty (1931–2007) who started proclaiming the death of metaphysics as such. The days of metaphysics as a privileged human (philosophical) activity aspiring to acquire a mirror cognition of *the Reality* in a metanarrative, absolutely valid and ultimate system, are over. Its common topics—truth, reality, humankind, history, mind, language—are no more perceived as being noumenal or transcendental in status. They are temporal—socially, historically, and linguistically determined. Metaphysics does not offer an absolute, genuine picture of reality; it is just one of the numerous narratives of reality, a mere rhetoric. "God's eye view" realism submits to relativism, monism to pluralism, totalization and sameness to the otherness, eternity to time and temporality.

Meteors and Meteorites

Both meteorites and meteors are classified more broadly as meteoroids, the simplest definition of which is a small body in space. The term *meteor* is applied to any streak of light in the upper atmosphere that is produced by a small body when it enters from space. They are more commonly referred to as shooting stars. Efforts have been made to predict and record the occurrence of the most impressive phenomena, and there is wide interest in observing them among both scientists and laypeople.

Meteorites are natural bodies that have managed to travel through the atmosphere to land on the surface of the earth. To accomplish this, they must normally be large and dense enough so that they don't crumble into fragments or vaporize completely. They are of great scientific interest because they provide an opportunity to examine extraterrestrial material older than any material found on earth. Whereas many of earth's early rocks have been destroyed by natural geologic processes, meteorites have remained unchanged since the birth of the solar system. It is now generally accepted that research to determine the age of the materials in meteorites will very likely help us to determine the age of our planet.

Knowledge about and attitudes toward meteorites have undergone significant change through the centuries. There is evidence that many ancient people did accept meteorites as heavenly bodies. Both meteors and meteorites inspired a variety of myths and folk beliefs, with the element of superstition emerging prominently during the medieval period. During the 17th and most of the 18th centuries, the possibility that meteorites had originated from beyond the earth was not even considered.

The last decade of the 18th century marked a distinct forward movement in the scientific study of meteorites. Luckily, witnesses were present when several thousand meteorites fell near L'Aigle in northern France. In 1794, Ernst Chladni, a German physicist, published a book asserting that bodies of rock and metal actually do fall from the sky. He is now considered the founder of the study of meteoristics.

From that time on, museums and interested individuals began collecting samples, making further research possible. At present there are around 1,000 samples available for scientific study. The earliest known meteorite still available for study fell near the village of Ensisheim in the province of Alsace in 1492.

Some specific scientific observations still lagged behind. It wasn't until the 1930s and 1940s that scientists concluded that some craters had originally been formed by the impact of meteorites.

Chrondites represent the most primitive kind of meteorite, making up about 80% of the total. They appear to have been formed with the same substances as the earth and other planets. Their composition is also very similar to that of the sun, with the exception that the sun also contains large amounts of hydrogen, helium, and other noble gases.

In the 1950s, Clair Patterson, of the California Institute of Technology, began the process of dating chrondites by a radiometric process that made use of a uranium-lead clock. He found their age to be 4.55 billion years, and the range of 4.5 to 4.7 billion years has been corroborated by five different radiometric dating methods. The basis for all of these methods has been the measurement of the radioactive decay that has occurred. About 70 meteorites have now been accurately dated. Radiometric dating has also been used to determine ages of many other subjects, including the earth, the moon, fossils, early humans, and a variety of geological events.

Comparing chrondites with rocks that appeared to have originated on earth, Patterson found a similar composition of lead isotopes. A logical conclusion is that both may have been formed when silicates condensed from the sun's nebula. It has also been concluded that the universe may be as old as 14 to 17 billion years.

Scientists now generally believe that most meteorites are pieces broken off when asteroids—or minor planets—collided. Asteroids themselves are large chunks of debris that circle the sun in the belt between Mars and Jupiter's orbits. Like the earth, these meteorites are composed mostly of silicates and metals. A few rare meteorite samples may have come from Mars or the moon, probably as the result of a crater being formed by another body impacting those surfaces.

In the 1980s, sediments from around the world were examined and found to contain chemicals of the same age. That suggested that a large body had slammed into the earth approximately 65 million years earlier. It is even possible that our moon might have been formed as the result of a collision between the earth and a body about the size of Mars.

It is estimated that about 30,000 meteorites with a mass larger than 3.5 ounces fall to the earth each year. They are classified by the amount of silicate and nickel-iron that they contain and fall into the three broad categories of irons, stones, and stony irons.

Meteorites are classified as falls or finds, and each is given a name that is usually based on the geographical area in which it fell. To be classified as a fall, the event must be witnessed. Because meteorites usually signal their arrival by a light display and a variety of sounds, it is not surprising that some are observed at the time of impact. Reporting of these events can allow scientific study to begin soon after the event. The largest recorded fall occurred in 1976, in Jilin, Manchuria. The total weight of its pieces was 2 metric tons.

The term *finds* applies to those that are discovered by accident and subsequently identified by the chemical and mineral content or their structure. The largest known meteorite find is the African Hoba meteorite, weighing approximately 66 tons.

The study of known meteorites is expected to reveal even more information about the solar system. The search for meteorites that are yet to be discovered will be ongoing. Two challenges that have been recognized are the need to search in the comparatively neglected desert areas and the need to identify very small meteorites.

Methuselah

The epitome of an extended life span lies in the biblical tale of Methuselah or Metushélach (מְתוּשֶׁלַח / מְתוּשָׁלַח), the longest living Hebrew patriarch. Humankind's quest toward great longevity has been a common mission throughout the generations. From scrutinizing ancient texts to the exploration of advancing modern sciences humankind has endlessly sought a proverbial fountain of youth.

Methuselah is credited with having lived 969 years, making him the oldest person in recorded history, yet little else is stated. He is mentioned in Luke 3:37 (King James Version) when tracing Jesus of Nazareth's lineage and is noted as being the father of Lamech, Noah's father, in Genesis 5:25–27:

> And Methuselah lived an hundred eighty and seven years, and begat Lamech. And Methuselah lived after he begat Lamech seven hundred eighty and two years, and begat sons and daughters: And all the days of Methuselah were nine hundred sixty and nine years: and he died.

In the year of the Great Flood, or the Deluge, he eventually died.

> As long as Methuselah lived, the Flood did not come upon the world. And when Methuselah died, it was withheld for another seven days after his death to fulfill the period of mourning. (Avot d'Rabbi Natan 32:1)

The direct etymology of the word *Methuselah* is "his death shall bring"; this translation comes from the roots *mûth,* meaning "death," and *shelach,* meaning "to send forth." Based on the etymological translation, the year of his death, and his remarkable age, Methuselah has often been cited as an allegory in which God withheld judgment upon humankind for a great period of time.

Some scholars, however, dispute Methuselah's age and theorize that it is in fact merely an error resulting from mistranslations of text and loss of documentation through the ages. Within several early biblical texts, the numbers were written in an archaic, precuneiform Sumerian number system in which the decimal is placed differently than in latter Sumerian number systems. Their theory is that in the year 1700 BCE the scriptures were initially mistranslated into a later Sumerian system and then mistranslated again in 550 BCE when compiling the Hebrew Genesis 5.

Another theory speculates that certain dates are based on a standard using lunar instead of solar cycles. This theory would convert Methuselah's age upon death to 87, and to 15 when he fathered Lamech. However, this lunar theory also has met with skepticism, because it results in other patriarchs, such as Enoch and Mahalel, being merely 5 years old when they fathered their own children.

Other scholars have accepted Methuselah's remarkable age as fact, yet have speculated how such a prolonged age was once feasible. Numerous theologians hypothesize that human life expectancy was shortened due to humankind's falling from God's grace. This credence is marked by the biblical examples of Adam, Methuselah, and Moses. Adam marks the end of possible immortality, Methuselah marks humankind's potential life span preflood, and Moses sets the modern standard of 120 years. A recent theory as to why Methuselah lived to be nearly a millennium old is that the human gene pool experienced a massive bottleneck at the Great Flood. This theory speculates that a drastic loss in population, caused by events such as the Deluge, would result in small gene diversity and a loss of certain inherited gene qualities. This could have resulted in the trait for longevity to be lost or hidden deep within our genetic code. Currently, numerous scientific efforts, such as the Human Genome Project and the Methuselah Mouse Prize, are striving to discover the secrets of increased longevity.

MICHELANGELO BUONARROTI (1475–1564)

Michelangelo di Lodovico Buonarroti Simoni is universally recognized as one of the greatest artists in history, perhaps the greatest. He excelled as a sculptor, painter, architect, and poet of the Italian High Renaissance. During his long life, Michelangelo created some of the world's most recognizable works of art.

Mastery in a variety of skills has earned Michelangelo the title of *Renaissance man*. He rivaled his fellow Florentine, Leonardo da Vinci, as the embodiment of this role. His most famous sculptures include the *David* in Florence and the *Pietá* in Rome. Although Michelangelo claimed that he did not enjoy painting, he created many remarkable works, most famously the series of panels containing more than 300 figures depicting the Creation, the downfall of man, and the promise of salvation—the entire core of Christian doctrine—on the ceiling of the Sistine Chapel in the Vatican. Michelangelo also designed the dome of Saint Peter's Basilica, which remains the largest dome of any church in the world.

An intensely spiritual man, Michelangelo focused on biblical themes throughout much of his work. He was deeply concerned with the notion of time, depicting such scenes as God's Creation of man and the universe. His fresco *The Last Judgment* portrays the future of humankind, as based on scenes described in Dante's *Divine Comedy.*

Michelangelo Buonarroti was born to a Florentine family in the village of Caprese, Italy, on March 6, 1475. He demonstrated great talent as a painter at an early age while apprenticed to Domenico Ghirlandaio. He studied sculpture under the guidance of Bertoldo di Giovanni and was soon commissioned by the foremost family in Florence, the Medici. Following a brief fall from power of the Medici in 1596, Michelangelo fled to Rome. There at the age of 23 he completed the *Pietá* that now stands in Saint Peter's Basilica in Rome. He returned to Florence between 1501 and 1504, where he met Leonardo da Vinci; the two artists were temperamentally very different and did not become friends. During this time he carved the famous statue *David.*

In 1505 Michelangelo again traveled to Rome on invitation from Pope Julius II, a patron of the arts. Michelangelo reluctantly accepted the commission to paint the ceiling of the Sistine Chapel in the Vatican, a project that would require heroic effort and consume years of his life. This highly renowned work includes masterful depictions of the most significant events from the Old and New Testaments of the Bible. Michelangelo also carved the tomb of Julius II, which includes a powerful statue of Moses. He returned to Florence in 1515 to design the Medici Chapel containing the tombs of Medici princes. These tombs include carved allegories representing day, dawn, dusk, and night.

Michelangelo again returned to Rome in 1534 in a period of political turbulence when Florence ceased to be a republic. Commissioned by Pope Paul III, he painted *The Last Judgment,* in which the souls of humankind either ascend to paradise or are cast into the inferno. In 1546 the pope appointed Michelangelo chief architect of Saint Peter's Basilica in Rome, where he began supervising the construction of its dome. Unfortunately, he did not live to see the dome completed. Michelangelo died on February 18, 1564, at the age of 89, and was buried in Florence.

MIGRATIONS

Migration can be defined as a total or partial change of location (habitat) and/or movement into new areas for a certain period of time or forever. The term *migration* is widely applied in social and human sciences as well as in biology, geophysics, astronomy, and computer sciences with reference to plants and animals, fish and birds, insects and cells, planets, systems, and data.

In contemporary social and human sciences, migration interpreted as population displacement (translocation) usually is viewed as one of the four basic genres of human activity along with habitation, storage, and creation. The term *migration* is an integral part of the professional terminology of contemporary archaeologists, ethnologists, sociologists, demographers, cultural anthropologists, and geographers. The sphere of its application and meaning seem to be so clear that some reference books consider definition and interpretation of this concept unnecessary.

Nevertheless more careful analysis of the application of the term *migration* indicates that this concept is often applied to processes as they vary along spatial and chronological scales, as well as in their ecological, economic, ethnic, and social consequences.

Migration in Social and Human Sciences

The concept of migration applies to studies of displacements of population (group and individual movements) as well as to dispersion of created artifacts and culture in general. Sometimes anthropological and other data indicate that culture transmission does not accompany its human substrate displacement; in such a case migration of ideas is assumed.

The possibility of culture migration was widely discussed in cultural anthropology at the beginning of the 20th century in the context of several schools and theories of diffusion. The notion of cultural diffusion, understood as spatial transference of cultural phenomena, was put forward by them; human history was interpreted as a series of cultural clashes, adoptions, and transfers. Long-distance contacts, such as international trade and exchange, conquests, and conscious imitation were regarded as basic ways by which certain cultural phenomena and/or artifacts could surmount considerable distances from the point of their primary origin.

The origin and rapid upsurge of genetics during the second half of the 20th century provided the possibility of verifying a hypothesis about the translocation of ideas and artifacts without human displacement; this could be done by comparing the genetic makeups of human populations in certain areas. Such DNA spatial distribution studies, brilliantly developed by Luigi Cavalli-Sforza at the beginning of the 21st century, have resulted in a series of gene-flow theories that have brought studies of human migrations taken in historical perspective to a higher level.

Migrations in Human History

Purposeful changes of habitat were inherent to human beings since the very origins of the species. Human dispersion over the Old World in contemporary prehistoric sciences is interpreted as a result of migrations of early hominids and early human beings. Colonization of the New World and the European North happened at the end of the Pleistocene—at the beginning of the Holocene ias the next important example of large-scale migrations in prehistory. Human migrations often are regarded as the driving forces of agricultural dispersion in the Old World as well as the basic mechanism of Indo-European language origin and dissemination.

The origin of nomads and the formation of the nomadic mode of subsistence, strategy, and cultural morphology, as illustrated by Cimmerians, Scythians, Sarmatians, and other nomadic communities of the early Iron Age, is the next phase of human history connected with migrations. The period between 500 and 700 CE, traditionally called the Migration

Period, was characterized by barbarian invasions all over Europe and was marked by the collapse of ancient world empires and a transition to a new, early feudal phase of human history.

Human migrations of medieval times—the Muslim conquest (the Arab migration across Asia, Europe, and Africa between 632 and 732 CE); the Turkic migration across the Middle East, Europe, and Asia (between the 6th and 11th centuries CE); the long-distance migrations of Mongol and Turkic tribes over eastern and central Europe (between the 12th and 14th centuries CE); the Ostiedlung (movement of German tribes to eastern Europe); and others—in most cases were caused by the necessity of modern ethnic and political structures to find their proper places in the early medieval community. Hence these displacements usually are mentioned among the crucial factors of the reshaping of medieval political structures (early and centralized states and empires), often accompanied by the origin of modern nations and the creation of the contemporary ethnopolitical map, which is well traced over Europe even today. These displacements also are associated with the formation of basic principles of modern geopolitics.

The era of discoveries and the Age of Exploration showed most Europeans the impressive economic potential of newly opened and intensively explored territories (e.g., America, Australia, eastern Asia, Siberia), and so the economic aspect of human migration became its dominant motivation.

The modern era has brought new impact into human migrations, connected, first of all, with displays of religious background of human migration (the great Puritan migration from England to North America in the mid-17th century, the great Serb migration from the territory of the Ottoman Empire to the domain of the Habsburg monarchy from the end of 17th to the middle of the 18th centuries). In addition, the migrations of the age of imperialism and industrialization were motivated by the necessity to improve the quality of life through finding new workplaces and trade opportunities (transatlantic migration of Europeans to North and South America, the mass migration of African Americans out of the southern United States during the first half of the 20th century, exploration of eastern and southern Asia).

World War II and the following cold war demonstrated the importance of the political and ideological background of human migrations based on necessity of free self-identification and self-expression.The contemporary trend in the direction and motivation for human migrations resulted from the the fall of the iron curtain, the end of the cold war, and the economic problems of the developing postsocialist and so-called third world countries of Asia and Africa.

Problem of Causes and Motivation, Diversity of Forms and Cultural Consequences

Migrations have been one of the basic forms of human activity since the origin of humankind, and since that time reasons, backgrounds, and motivation of human displacement have continued to change in accordance with priorities and emphases of human culture and the development of various livelihoods. In contemporary social science, the problem of migration's causes and motivation usually is conceptualized through a system of "push and pull" factors mediated by "barriers and obstacles." Among the most influential push factors, one can distinguish among the restriction of subsistence resources (work shortage, low trade opportunities, low income), threats to human life (environmental disasters, poor medical care, insecurity, armed conflicts), the impossibility of free displays of political, ethnic, and religious self-identification, and restrictions on emotional life, family links, and education. Pull factors, in contrast, provide the possibility to overcome the restrictions imposed by push factors, and to change living conditions for the better.

The concept of human migration currently is applied to a rather wide variety of forms of human displacement that differ by their positions in space and time, by their mode of their personification, and by their motivation—whether migrators travel of their own free will or based on coercion.

Personification of Human Migration: Group and Individual Displacements

Defining the factors underlying instances of migration shows the diversity of its forms and genres; here the opposition of the individual versus the group character of migration is especially acute. History shows examples when translocations of individuals of separate families were the first steps of large group migrations, waves of which involved sometimes the population of the whole administrative unit (immigration to the United States). The opposite has also occurred; in the past one can find situations when a first impressive wave of group colonization was followed only by separate individuals or was not supported at all (primary colonization of Australia).

Detection of the social, ethnic, political, religious, economic, or other background of migrant groups' formation currently is at the center of the fields of demography, cultural geography, and cultural anthropology as well as of other social sciences dealing with the causes that force people to leave their dwelling place and search for another, more suitable one. Environmental and geographic parameters of primary living space were the agencies of principal importance in prehistoric and preindustrial societies, while in the contemporary world these have yielded to sociopolitical agencies.

Infiltration is a peculiar form of small-scale group migration that implies movements (often secret ones) of a restricted number of participants within a restricted time and chronological span. Usually infiltrations take place at the stage when a group is choosing its destination. Also this term could refer to attempts of small groups to cross a state border or guarded space illegally (contemporary Palestinian border infiltration).

Human Migration Distance Scale: Colonizations and Relocations

The geographic and spatial dimension of migrations is another factor giving rise to diverse forms of this process as well as to the variety of its sociocultural implications and consequences. One can distinguish long-distance movements (or colonization) and comparatively rapid movements (or relocation).

Colonization is regarded as durable and in most cases long-distance and repeated (wave) movements of human collectives (never individuals) to previously empty (i.e., unsettled by human beings) places. Their earliest examples in human history are the exodus of *Homo habilis* and *Homo erectus* (the first representatives of the genus *Homo*) from Africa, which happened at the beginning of the Pleistocene. Primary colonizations of America and Australia happened at the end of the glacial period and are regarded as the traditional examples of Upper Palaeolithic (i.e., earliest realized by anatomically modern humans) migrations of such a type. The times of glacial retreat and during the Holocene period had comparable results in the colonization of northern Europe: the Baltic region, Scandinavia, Greenland, and so on. Further colonization processes were directed toward mastering free niches in areas already more or less intensively explored.

The general tendency and intensity of colonization processes, as well as their typical undulating, multistage, and multilevel character, opens the possibility of interpreting them as phenomena with not only historical, cultural, ethnic, and economic consequences but also geographic and ecological consequences. In such a context, colonization is one of the basic features of general human evolution that causes a long-lasting effect on the landscape structure of human natural habitats.

Relocations are regarded as relatively strictly defined in time, isolated changes of habitat realized by a group or by individuals with a particular purpose. This category covers the overwhelming majority of all known historical and contemporary migration cases. Even at first glance one can distinguish at least two sorts of relocation: (1) transmigration, or population displacements that significantly enlarge or totally change the habitat of a particular group, and (2) movements of individuals or human groups of a different genre (social, gender, cultural, ethnic, professional, etc.) within their traditional living space.

Transmigration is more likely to be the means of preserving a group's culture in new territory but in the same ecological situation; in the case of oncoming movements, it is obviously one of the forms of ethnic contacts.

The Timescale of Human Migration

In accordance with the period during which human translocation takes place, it is possible to distinguish daily, episodic, seasonal, cyclic, and pendulous migrations and population movements with long-lasting consequences, or irretrievable migrations.

Daily migration implies traveling between residence places and working places, usually marked by the notion of "daily commuting" or "pendulous migrations." Daily migrations could be long distance (especially in hunter-gatherer societies and, sometimes, in contemporary highly urbanized areas and megalopolises), but in most cases transportation time does not exceed working time. This form of migration is practiced by the majority of the contemporary population and currently is showing a gradual but stable tendency of proportional growth.

The notion of *episodic migration* is used to define business, recreation, shopping, and other trips realized from one center of permanent or semipermanent occupation; such translocations usually are irregular and could engage different routes and paths as well as differ in their spatial scales.

Seasonal and cyclic migrations are practiced mainly by the able-bodied population moving to their temporary working places (often seasonal ones). Such translocations usually cover several months and include the possibility of return to migrants' permanent residential place. Cyclic migration recurrence can be related to employment (e.g., military service, seasonal agricultural jobs) or to peculiarities of economic cycles, which, in turn, usually are geographically and/or environmentally determined (as in the cases of horizontal migrations inherent to nomadic pastoral farming and of vertical migrations in other social groups"). Rural-urban and urban-rural migration also could be regarded as a special case of cyclic migration. In the case of cyclic migration, usually only part of a social group is moving, while the rest of the population (mostly women, children, and the aged) remains at the permanent or semipermanent living place.

Migration with long-lasting consequences, sometimes called irrevocable migration, usually involves long-distance movements and is accompanied by total changes of permanent residence of individuals or a certain group as a whole. In most cases such migration is external and stipulates dislocation not only between administrative units, but also between countries. In the case of colonization, irrevocable migration is the only source of permanent residents in newly explored territories. If displacement is directed to already inhabited and actively explored regions, most widespread forms of migration with long-lasting consequences are emigration, or leaving one's native country to live in another, and immigration, or coming to a foreign country to live. Neither of these last forms of migration could be declared irrevocable as far as durability of their consequences depends on people's free will and the coercive actions of authorities in their former and new countries.

Human Migration as an Act of Free Will Versus a Coercive Action

In the contemporary world, migration flows tend to be regulated by separate countries' authorities and are also subject to international legislation. In the context of the political realities and international relations of the second half of the 20th century and the beginning of the 21st century, a series of human migrations resulting from coercive actions of national governments (forced migration) can be distinguished. These include *deportation,* or coercive expulsion imposed on foreign citizens or individuals without citizenship; *repatriation,* or forced return to the home country of citizens who due to different (mostly unfriendly) circumstances have appeared on the territory of other countries; and *expatriation,* or eviction from the native country usually accompanied by denaturalization.

In contrast to migrations resulting from coercive actions of national governments and international institutions, some forms of human migrations could be regarded as acts of migrants' own free will. Thus, *re-emigration,* akin to repatriation, is realized mostly on the basis of conscious choice and maintained by international legislative acts, such as the Geneva Convention on victims of war. Expatriation also could be the conscious act of protest against certain actions of the native country. All forms of *illegal migration* are derived exclusively from the free will of migrants; nevertheless this free will usually has a fundamentally sociopolitical, economic, or religious background. *Chain migration,* widely applied in the contemporary immigration policy of the United States, allows foreign citizens to naturalize in the country on the basis of the acquired citizenship of their adult relative. The idea of migrants' free will expressed in their displacements is the basis of the concept of *free* or *open migration* with its emphasis on people's freedom to move to whatever country they choose as most preferable for their self-realization. *Brain drain,* or emigration of highly qualified professionals in the field of fundamental and applied sciences and hi-tech, could be regarded as a special case of free migration.

Milton, John (1608–1674)

John Milton was an English poet and political critic, celebrated for his epic poem *Paradise Lost* (1667). In it he deals with the biblical account of Creation and the place of humankind in time. Total blindness late in life forced Milton to write this poem and others through dictation.

Milton was a devout Puritan with a deep interest in the Bible. His writing often deals with religious themes. His masterwork, *Paradise Lost,* is an immense poem in 12 books. It describes God's Creation of Adam and Eve in the Garden of Eden and their subsequent fall and expulsion. The poem describes the biblical story of Creation of the earth and the universe as well as of hell and the emergence of the devil (Lucifer). The devil is given a prominent role in Milton's poem, characterized as an overly ambitious angel banished from heaven. The timeless struggle between God and the devil, or good versus evil, is a major theme in the poem. Eve notoriously yields to the devil's temptations, resulting in the loss of paradise for humanity. Milton also argues for the doctrines of predestination and salvation.

John Milton was born in London on December 9, 1608. He attended Christ's College, Cambridge, from which he graduated with a master of arts degree in 1632. He demonstrated an interest and ability in writing poetry while a student. Following graduation from college, Milton retreated to his family's summer home in Horton and devoted six years to private study and poetry. His works from this period include *Comus* (1634), a masque, and *Lycidas* (1637), written to commemorate the death of a close friend. In 1638 Milton left Horton to take a tour of Europe, meeting the astronomer Galileo Galilei in Florence. He returned to England during the civil war to write political pamphlets defending the Puritan cause. These include *The Tenure of Kings and Magistrates* (1649), which argues that the people have the right to remove a tyrant from power. The Puritans won the civil war, and King Charles I was beheaded.

Milton was married three times. The unhappiness of his first marriage led him to write *The Doctrine of Discipline and Divorce* (1643). He wrote *Areopagitica* the following year in defense of the freedom of speech. The government of Oliver Cromwell appointed Milton to the post of secretary of foreign tongues, where he oversaw the translation of dispatches into Latin. In 1652 Milton suffered a permanent loss of his eyesight. Thereafter his work had to be dictated to an assistant. In spite of this challenge, Milton's final years were highly productive. He published *Samson Agonistes* and *Paradise Regained* in 1671. *Paradise Regained* deals with the future of humankind. These and Milton's other works have had a lasting impact on world literature and have influenced artists and writers for more than 400 years.

Moon, Age of

The moon, a natural satellite of the earth, was formed at approximately the same time as the earth, roughly 4.6 billion years ago. The origin of the moon remains the subject of debate; differing theories have been advanced, each with its merits and defects. Scientists have created a lunar geological timescale and used radiometric dating methods to aid in estimating the age of the moon.

Theories explaining the formation of the moon include the fission theory, capture theory, cocreation, and collision-ejection theory. The fission theory states the moon was a piece of the earth that broke away in an early stage of the planet's development. The circumstances for this event to have occurred are considered somewhat implausible.

The capture theory states that the moon was an asteroid, or another similar spatial entity, that was pulled into orbit by the gravitational field of the earth. This theory is improbable given the size of the moon and the gravitational force needed to trap it.

The cocreation theory states the moon accumulated from the debris orbiting the earth as it, too, was forming. This theory succeeds in explaining the similar ages of the two bodies, but it fails to explain the difference in composition between the Earth and the moon.

The collision-ejection theory is the favored theory; it combines aspects of the different theories into one unified theory. It theorizes that an asteroid, possibly the size of Mars, collided with the earth, ejecting debris from both bodies and merging the fragments into one. The fragments fused over time while captured in an orbit around the earth. This theory is fairly consistent with the known facts about the moon.

The moon has its own geologic timescale consisting of five periods. Unlike the earth's geologic timescale, there are no subdivisions of these periods due to the insufficient amount of information available. Two of the major reasons for this lack of information are the limited accessibility of the moon and the nonexistence of fossils, which helped to detail the geological timescale of the Earth. A lot of what we know about the moon is through distant observations and rock samples returned from numerous lunar missions.

Using relative and radiometric dating methods, scientists have been able to determine that the moon sustained a period of bombardments after the surface solidified. This accounts for the vast number of craters across the moon's highlands. Toward the end of this period, known as the Nectarian period, asteroids 100 kilometers in diameter collided with the moon, leaving enormous craters. These craters were later filled with basaltic lava during the next 500 million years, also known as the Imbrian period. Early earthbound observers believed these lava-filled craters, long since solidified, to be large bodies of water and dubbed them *maria,* or seas.

Scientists tested the rock samples from lunar missions using radiometric dating methods. The age of these rocks varies between samples from the older highlands and the younger maria. The samples range from 3 to 4.5 billion years old. The older rocks confirm that the moon was formed when the earth was in a primordial state.

Moon, Phases of

The phases of the moon have played an important role in the determination of time. The word *month* is directly derived from the word *moon.*

Traditionally, one month was equivalent to one revolution of the moon around the earth. As the moon orbits the earth, the visible reflective portion (called the lunar disk) seen from the earth varies in predictable patterns. At the beginning of the cycle, the moon is a very thin crescent that increases in size within hours. Because the full cycle of the moon is not exactly 28 days, a day-length based on the rising and setting of the moon results in inconsistent solar positions during the daytime.

Lunar Calendars

A lunar calendar is divided into even periods between phases. In using a lunar calendar, for example, the solstices and equinoxes are never the same. This calendar, utilized by the Greeks, was devised by the philosopher Metones of Athens and bears his name as the Metonic cycle. The Metonic cycle is equivalent to 19 solar years or approximately 235 lunar months. The lunar calendar was eventually abandoned, as it never remained evenly synchronized with the annual solar cycle. The Romans devised their own solar calendar to replace the Metonic calendar.

Lunar Phases

Lunar phasing is the visible change in the daily appearance as the moon orbits the earth. There are four major phases: new, first quarter, full, and third quarter. Additionally, the moon passes through phases as it rotates on its own axis. In modern times, the new moon occurs when the moon is positioned relatively between the sun and the earth. Because the moon orbits the earth at an inclined angle with respect to the earth's revolution around the sun, the moon is not always in a direct line between the sun and the earth (see Figure 1). Occasionally, a solar eclipse occurs when the moon does get into direct position, and the moon's shadow darkens the daytime skies of earthbound observers. At the new moon, the lunar age is zero days. Lunar age is defined as the number of days from the last new moon.

New Moon to First Quarter

As the cycle progresses, the lunar disk continues to gain luminescence (wax), and a crescent shape appears to the right of the lunar face. This stage is known as the waxing crescent and continues for approximately 7 days. To the observer, the moon shifts approximately 12° per day, an effect that causes the moon to rise 48 minutes earlier each day as it lengthens an apparent gap between itself and the sun. Occasionally, when atmospheric conditions are met, the darkened portion of the lunar disk can be seen as a very dull, gray feature in contrast to the illuminated area. This effect, called earthshine, is caused by the reflection of direct sunlight from the earth projected onto the moon (see Figure 2). Earthshine is best viewed when local weather conditions are clear, and the relative humidity is low. Another factor of waxing earthshine magnitude is cloud cover over a location westward of the observer. Clouds reflect more sunlight than land and water reflect.

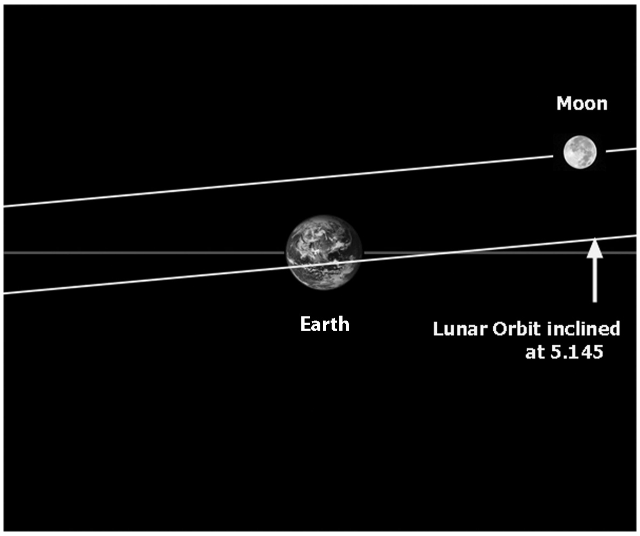

Figure 1 The moon's inclination to the Earth's orbit

Notes: Distances and diameters are not drawn to scale. The visible inclination is drawn to scale.

First Quarter to Full Moon

At the age of 7 days, the moon reaches a relative right angle with the sun and the earth (earth at the apex); the right half of the lunar disk is visible to the terrestrial observer. This phase is the first quarter, and the term quarter refers to two aspects. First, the moon has completed one quarter of its revolutionary period, and second only one quarter of the lunar sphere is visible. At this location, the

Figure 2 Earthshine on the lunar surface

Source: James P. Collins, reproduced with permission.

Note: The lunar cycle in this photo is 2.5 days old.

moon is exactly 90° east of the sun. Once the moment of the first quarter has passed, the moon continues to wax; yet, the crescent shape appears on the left, unlit portion of the lunar disk. This stage is a gibbous stage; therefore, the term *waxing gibbous* is used to describe the luminescent increase from the first quarter. This process continues for 7 days, after which time the moon gets to the halfway point in its revolution.

Full Moon to Third Quarter

The full moon occurs when the entire lunar disk is illuminated at an age of 14 days. Although it is not widely known, the full moon is technically considered second quarter phase. Throughout history, we have applied the term *full moon* to the visible portion of the lunar disk. However, this is a misnomer, as in reality the moon is a sphere, not a disk, so only half the lunar sphere is truly reflecting the sun's light. At this point, given the right circumstances on the inclined lunar orbit, we can see the moon passing into the shadow of the earth, resulting in a lunar eclipse. Lunar eclipses are much more common than solar eclipses due to the earth casting a bigger shadow over the moon than the moon does over the earth.

From the moment of the full moon, lunar disk illumination begins to recede (wane). Marking the second half of its revolutionary motion, the crescent face of the moon is again on the darkened side; however, the darkened portion shifts to the right side of the moon. This stage is termed *waning gibbous*. During the current lunar cycle, 21 days has elapsed.

Third Quarter to New Moon

The moon forms another right angle with the earth and sun and has now reached the third (last) quarter phase. From earth, the left side of the moon is illuminated and is exactly 90° west of the solar position. As lunar disk recession proceeds, the crescent shape returns to the left side of the lunar disk, and the stage is called waning crescent. During this stage, earthshine is prominent again; however, the magnitude of the projection depends on what is eastward of the observer's location. Figure 3 depicts the entire lunar cycle from start to finish. As it completes the nearly 28-day cycle, the moon is visible in the early morning until it returns to its starting position between the earth and sun, at which point none of the lunar disk is visible, as it is lost in solar glare. The new moon, under the right conditions, will provide a solar eclipse on earth.

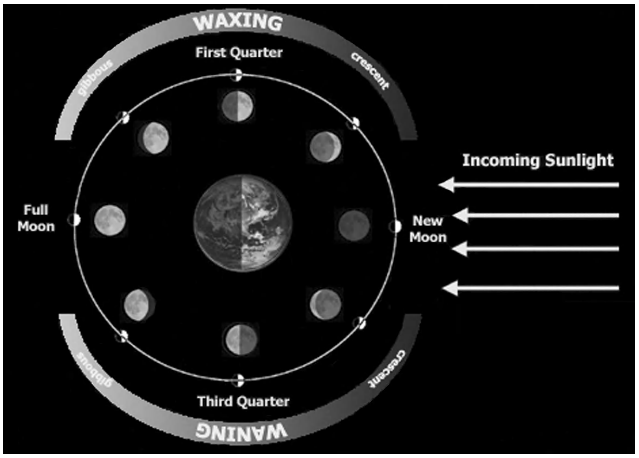

Figure 3 Complete lunar phasing diagram

Notes: As the moon orbits the earth, the sun illuminates half of the lunar sphere. Inside the lunar orbit is a photograph of the moon as seen on the observer's local meridian.

Period Lengths

The lunar sidereal period is one complete lunar cycle. It is equal to 27.321661 days, or the time needed for the moon to revolve around the earth. However, as the moon moves around the earth, the earth is moving around the sun. Observationally, it takes time for the moon to return to the local meridian over its orbital period around the earth. The earth has proceeded in its own orbit, and as a result, the terrestrial observer's moon has not quite reached the same location. When it does, it will have completed one lunar synodic period, which is equivalent to 29.53 days.

During the course of a lunar cycle, the positions of the craters tend to change slightly. Lunar libration is the apparent wobble of the moon as it revolves around the earth caused by the difference in inclination between the earth and moon, the shape of the moon's orbit, and the effect of the earth rotating, creating a parallax shift from the observer's perspective. Although the moon's daily rotation is locked to the terrestrial rotation, these factors result in approximately 10% more surface feature visibility. Time-lapse photography of all the lunar phases results in a slight shift in the daily positioning of lunar features such as craters, mountain ranges, and lunar maria or seas.

Morality

Broadly considered, morality encompasses all beliefs and practices associated with our concerns about humans and human conduct, along with all that we conceive or do to improve ourselves or others, all that we conceive or do to improve the world, and all that we conceive or do under the feeling that we must, should, or ought to, for any reason. It specifically includes all that we conceive and do, or don't do, either for or against what we think of as base, bad, evil, wicked, wrong, immoral, unjust, or cruel, by any name, whether in ourselves or in the world. It also includes our assessments of humans and their effects on the world, including assessments of human actions and human efforts, whether in gardening, governing, writing, dance, or sport. At this broadest level of description, almost all thought either is, or is importantly impacted by, moral thought. Given its emphasis on controlled or directed change, morality is implicated in every aspect, or almost every aspect, of our thinking about time.

Theory and Morality

Because it is otherwise too broad and unwieldy, most theorists restrict their conception of morality so that it encompasses only traditional practices and beliefs that are specifically concerned with human conduct toward persons. But even under this severe limitation, it still names a feature so general and pervasive that one cannot help but think of morality as fundamental to our lives, for nearly every greeting, parting, and discussion exhibits easily identifiable, traditional practices concerned with the well being of persons.

In the most remote reaches of theory, traditional expectations about conduct toward persons are encountered at every level. For example, in the sciences, where we expect to help one another find true statements, we also expect to be able to trust researchers to be honest about their findings. Intentional violations of these expectations about the conduct of colleagues have traditionally been severely dealt with. These dimensions of science as a moral enterprise are complemented by another, in which science is motivated by moral beliefs, such as the belief that science benefits humanity, or that its practice improves one's character. In the austere world of epistemology, morality is found in an ethics of belief formation, which proposes that it is wrong to form beliefs on the basis of inadequate evidence, not because the beliefs formed that way will be unreliable but because forming them that way is unethical.

Morality is also found in questions about the normativity, that is, the compulsory quality, of rules, rule-bound inference, and rational thought. Attempts to reduce epistemology to morality continue to receive many a hearing. Ethics, the branch of philosophy concerned with morality, has often been aided in its studies by metaphysics, the branch concerned with descriptions of reality. Together, they have produced centuries-long discussions about the nature and conceptual status of the self, obligation, value, evaluative judgment, pain, pleasure, envy, sympathy, privacy, freedom, conscience, justice, rights, acts, sin, redemption, and dozens of other morally charged items.

Questions about the spatial and temporal standing of these items are perennial sources of philosophical and theological lucubration. Is obligation extended in space? How, if at all, is it extended in time? Is the will temporally limited? Is sympathy? Is justice? The aging self and responsibility pose many a conundrum. At what point, if any, am I no longer liable for any one of the most minor moral lapses of my youth? And in what sense, if any, could I be responsible already for something I do in the future? If God is omniscient, and thus already knows what I will do tomorrow and every day after that, then am I really free? Doesn't an omniscient God entail a universe without free will and therefore without moral responsibility?

Among the more daunting problems arising for moral theorists who think about time is the problem of moral change. It is challenging merely to say what moral change is a change of. Shall we think in terms of changes in an individual's moral thinking, or that of a society? In both of these directions further questions await. Is it an alternation in conception? Rules? Judgment? Sentiment? Brain structure?

Consider a child who has moved from tolerance for the dismemberment of live grasshoppers to intolerance for it. An answer to the question of what has changed will determine how we explain it. If we think that he has altered his judgment, we might then imagine that he has learned a new rule, so that the set of moral rules he understands has grown by one. We might then hope to explain that acquisition environmentally. Perhaps an adult told him it was wrong or cruel. However, he might have long understood the rule that it is wrong to harm small creatures, but only recently began to conceive of grasshoppers as small rather than large creatures. In that case, his rule set remains the same, and the alteration of his judgment is based on a new way of classifying creatures. Thus, what needs to be explained is not a rule acquisition, but a new application of an old concept.

However, it is possible that his conceptions and rules have remained the same and the change we see is something else, such as a change in sentiment or taste. In that case, we might seek to explain his new attitude in developmental terms. Perhaps he has acquired sympathy for grasshoppers, or grown averse to the sight of struggling animals. This kind of change might then be explained in physiological terms, so that the child appears to acquire new attitudes because his brain is becoming more sophisticated. In this scenario, one will be tempted to conclude that moral changes in the child are not changes of judgment per se, but changes in something prior to and more fundamental than judgments that are in turn reflected in altered judgments.

The development of moral understanding in the individual might be studied by psychologists or biologists, while philosophers and historians are more likely to take an interest in social and cultural levels of description. At this more general level, the difficulties found in the individual case are multiplied and complicated, because a change at this level might involve more factors.

Moral Change

One may tackle the problem of collective moral change by tying the object of study to traditional judgments. At any given point in human history, there is a prevailing or traditional evaluation of typical, widely recognized practices, such as war, slavery, usury, monogamy, homosexuality, and cremation. At any other significantly distant point in human history, the prevailing traditional views of these same practices are likely to be very different as compared to those at the first. When the difference is plainly due to geography, or to a long temporal distance, we can speak of differing moral traditions. We can then restrict ourselves to speaking of moral change only when the difference is found in the same tradition at different times, and we can say that changes in prevailing traditional views are the moral changes we seek to study and explain. Although this is a simple and elegant first move, many difficulties await.

Consider a tradition that formerly disapproved of cremation but now shows a wide tolerance for it. Attempting to explain this change in traditional views will bring our system of thinking face to face with the fact that, as in the earlier case, these differing judgments might reflect a change in something more basic than judgments, such as rules, concepts, or sentiment. In addition, it could be that the alteration in reported judgments reflects a change in social or political conditions, such as an influx of cremation-favoring immigrants or the rise of a cremation-favoring regime. In the first case, demographics can account for the change in prevailing attitudes, while in the second, what we are proposing to treat as moral judgments might be nothing of the sort, because people might privately hold traditional anticremation views while tactfully compromising with the new authorities by publicly expressing only cremation tolerance. This possibility illustrates a difficulty in identifying moral views for study—when does a publicly expressed moral judgment express a moral belief, rather than tact, supererogatory good manners, or a fleeting taste?

Absolutism and Relativism

One means of avoiding all of these problems simply denies that there is any such thing as moral change. Moral absolutism is the thesis that there is only one moral standard that is universal, eternal, and static. Though the standard may remain undiscovered, it is not subject to change. Thus, for example, if slavery is in fact immoral, then it was always immoral, for all persons and at all times, regardless of the fact that it has been widely practiced and tolerated for many centuries and in many lands. For the absolutist, theorists of moral change study only the alterations of fickle human judgment, not morality as it is. That, they believe, never changes, and the problem of moral change is no problem at all, but a mistaken intellectual pursuit.

Ethical relativism, on the other hand, holds that moral standards depend on time and place and thus are subject to change as circumstances change. Morality as the absolutists describe it does not exist. What exists are human contrivances—rules, laws, agreements, conventions, knowledge, and expectations. For the relativist, the existence of morality implies a specific time and place. For the absolutist, it implies no particular human location at all.

Cognitivism and Noncognitivism

If all problems having to do with setting up the study of moral change could be handled, explanations of moral change would encounter further difficulties from the fact that moral beliefs, whether at the individual or cultural level, can be understood in either of two ways that are deeply incompatible.

One way emphasizes rational thought, while the other emphasizes nonrational, historical, or causal processes. The former method implies cognitivism, the view that moral judgments are the kinds of statements that can be either true or false, while the latter goes in the direction of noncognitivism, in which moral judgments, such as "cremation is an acceptable practice," are the kind of statements that cannot be either true or false. If moral beliefs are cognitive, then a decision to break with a traditional view in favor of a nontraditional one can, at least sometimes, be taken because the nontraditional view is or seems true, more plausible, more likely, or more probable on some moral ground. For example, duty might require that cremation be tolerated when duty is conceived as doing what is best for the health of the community, and cremation is discovered to be healthier than its alternatives. Or, where there is oppression of cremation supporters, a sense of justice might demand a more tolerant view of the practice wherever justice is taken to imply equal rights.

Causal and Normative Theories

If they are noncognitive, moral beliefs are held due to causal necessity and not for moral (or any other kind of) reasons. Many theorists account for moral change causally. The Marxist looks for economic forces to explain moral changes, the Freudian looks for psychosexual causes, and the postmodernist seeks underlying hegemonic powers. But all agree that moral beliefs are not held on the basis of moral insight, moral judgment, or morally based rational decisions of any kind.

In contrast to these causal theorists, normative theorists hold that moral changes are, at least in some cases, morally justifiable. If there are justifiable moral changes, it would be because the new attitudes reflect better normative insights or better moral reasoning or cognition. In holding that some moral changes can be morally justified, these views endorse the basic elements of a belief in the possibility of moral progress.

Normative theorists often search for rational grounds for holding to views different from prevailing or traditional moral views. The traditional view is likely to be held by most of the persons native to a given place and time. It is usually beneficial to hold the prevailing view, especially when we have no interests at stake. Nevertheless, rational insights might be capable of creating the conditions for disinterestedly accepting nontraditional moral beliefs. To begin with, one can become aware that norms in one area violate norms accepted in another area, rendering the tradition, which can be thought of as a body of practical knowledge, internally inconsistent. Perhaps the realization that abuse of pets is a felony, while the abuse of livestock is not, creates discomfort and prompts questions.

Other Conditions

In addition to inconsistency, general rules might prompt alternative moral views. For example, 19th-century Quakers strove for moral purity and clear conscience. On this basis they refused slave ownership due to its high likelihood of polluting the soul with unnecessary distresses of conscience. Meanwhile, knowledge of history and alternative traditions offer abundant examples of moral attitudes that contrast with those of our local tradition and can form a basis for criticism of it. A process based in this kind of reasoning appears, for example, when the ancient world's tolerance for homosexuality is employed to criticize less tolerant contemporary attitudes, or when attitudes toward a practice, such as prostitution, in a foreign tradition are appealed to in criticizing local attitudes. In the same way, knowledge of the Quaker attitude toward slavery could supply a moral example for non-Quaker critics of the practice.

Rationally justifiable alterations in traditional moral views might also be caused in part by a change in social conditions. John Langbein has argued that moral attitudes toward judicial torture evolved rapidly toward intolerance only after confessions ceased to be requirements for convictions in the most serious cases. Until this change in the law, moral criticisms of torture could gain little public footing. More recently, Lynn Avery Hunt has argued that the 18th-century appearance of the epistolary novel and the accompanying rise of portraiture allowed large numbers of people to grasp and to empathize with the subjective experiences of people very unlike themselves. On the basis of these new arts, talk of inalienable rights was able to move from the rarefied air of Enlightenment philosophy into the streets and, just as important, into the homes of the powerful.

More, Saint Thomas (c. 1477–1535)

Thomas More, in former times also called Thomas Morus, was an English statesman, attorney, and author of humanism. More served as lord chancellor from 1529 to 1532. He was executed on the king's orders for refusing to accept the secession of the English Church under King Henry VIII from the Catholic Church of the papal Holy See. Today More is seen as an ideal of steadfastness in defense of morality and conviction, especially among Roman Catholics. More was declared Saint Thomas More in 1935; Pope John Paul II made him the "heavenly Patron of Statesmen and Politicians" in the year 2000. He is considered founder of the literary school of Utopia, picturing a vision of an ideal society.

More was born on February 7, 1477 or 1478, in London, the eldest son of the eminent and prosperous judge Sir John More. After attending St. Anthony's School and spending some time as a scholar with the lord chancellor and archbishop of Canterbury Cardinal Morton, More entered the University of Oxford in 1492. There he studied history, logic, and the classical languages. In 1494 More left the university to study law in London, where he became a lawyer in 1501 and was elected a member of parliament in 1504.

The following year More married Jane Colt, with whom he had four children. Upon the death of his wife in 1511 he married again.

By 1510 More had become an influential public servant in the city of London. In 1516 he became a diplomat of the crown for a short time; then, in 1521, he was knighted and appointed subtreasurer of the court. In 1523, More became speaker of the House of Commons according to the will of the influential confidant of the king, Cardinal Wolsey. In 1529 More was appointed the first layman in the history of England to become lord chancellor. Being known for refusing any Protestant influence in his new function, he also soon acquired a reputation as a persecutor of so-called heretics.

Starting around 1530 More ran into deep conflict with King Henry VIII, triggered by the latter's attempt to cancel his marriage with Catherine of Aragon and the king's later self-proclamation as the "Supreme Head of the Church," culminating eventually in More's absence on the occasion of coronation of the succeeding queen, Anne Boleyn. In 1532 the king finally accepted More's second request to resign as lord chancellor. Then, in a campaign against him driven amongst others by his successor Thomas Cromwell, More was charged several times and for different arbitrary reasons, imprisoned in the Tower of London, and deprived of any income and land. On July 6, 1535, five days after his sentence in an unjust trial for high treason, More was beheaded.

Literary Work and Influence

Notwithstanding his manifold duties, More left a rich humanistic literary legacy; as an author he was influenced by his correspondence with his friend Erasmus of Rotterdam. More's primary literary achievement is *Utopia* (1516), a thought experiment and a humoristic critique of the zeitgeist in which More flings off the restraints of his own times and describes an imaginary, ideal, tolerant, humanistic society. More thus became the originator of a new literary style and a mode of dealing with time and present circumstances that would exert considerable influence on thinkers in the centuries to come. *Utopia* is said to even have influenced Karl Marx, despite the fact that the communism More pictured was religious.

Furthermore his *History of King Richard III* (1518) attracted attention not only as a dispraise of Richard III but also as a cryptic critique of the royal totalitarianism of the ruling Tudors. This work exerted an influence on William Shakespeare's play *King Richard III*.

Thomas More was beatified in 1886, was canonized in 1935, and received the title "heavenly Patron of Statesmen and Politicians" in the year 2000. Especially his canonization is thought to have been intended by the Vatican to form a strong warning against the inhuman and un-Christian conduct of German National Socialists as well as of Soviet Communism. Thomas More, who preferred to die rather than betray his firm ideals, still serves as a symbol of humanity and a just societal order.

Morgan, Lewis Henry (1818–1881)

Although Lewis Henry Morgan (1818–1881) was a successful New York attorney in the mid-1800s, he is remembered as a pioneer in the fledgling science of cultural anthropology. Morgan focused his study on the Iroquois Native American tribe, particularly the Seneca. His objective observations and chronicling of their daily cultural routines became the basis for the study of ethnology as we know it today. He is also credited with applying the idea of evolution to cultural behavior. Accordingly, some have called him the father of American anthropology. Scientists following Morgan's model have recorded the traditions of peoples that have since been acculturated to modern society, and their works have preserved these peoples' customs for future generations to study.

Morgan was born on November 21, 1818, in Aurora, New York. Little was recorded about his personal life. He attended Union College and earned his degree in law in 1840. Lewis married Mary Elizabeth Steele in 1851. His legal practice was very lucrative, and over the span of his career Morgan amassed a small fortune. He was greatly respected among his peers and served in the New York State Assembly and Senate.

Morgan's wealth allowed him to pursue his interests outside of the courtroom. One of his law clients was Ely S. Parker, a prominent Native American engineer and member of the Seneca tribe. Morgan's relationship with Parker inspired him to learn more about the native culture of the region. Setting out to learn firsthand about the customs and traditions of the Iroquois, he spent years immersing himself in the culture of the Seneca people. In 1847 he published his observations in a series in the *American Review* entitled "Letters on the Iroquois." In 1851 he released a longer work, *The League of the Iroquois,* explaining the social and political structures of this tribe. This is considered one of the first ethnographies, or scientific descriptions, of an ethnic group.

These studies led Morgan to think about the social structures of all societies and peoples around the world. He took a broad approach in examining the kinship systems and clan organization of many different cultures. Such a scientific approach to culture and behavior was a new concept in the 19th century. Morgan wasn't interested in individuals or societies in the ancient past but in the interactions of people in his contemporary world. He was also curious about how culture changed through time. As were many of his contemporaries, he was influenced by Darwin's theory of biological evolution and tried to apply it to cultural behaviors.

Morgan theorized that culture progressed unilinearly through time and that there have been three stages in cultural evolution; savagery, barbarism, and civilization. He linked technological progress with social change and published these ideas in *Ancient Society* in 1877. For better or for worse, he is often associated with the movement of social Darwinism, although he seemed to support equality for all ethnicities.

As did members of the legal community, his fellow scientists held Morgan in high regard. In 1879 he was elected president of the American Association for the Advancement of Science. He became an official adopted member of the Iroquois tribe and was given the name *Tayadaowuhkuh,* meaning *bridging the gap*. Morgan died on December 17, 1881.

Mortality

Mortality is defined as "the quality of being mortal or subject to death." Death is the permanent end or ceasing of the life of a biological organism. A common thread that links all living creatures is the fact that someday they will die. Unlike their fellow creatures, human beings are aware that they are mortal and have devoted much of human history to the pursuit of overcoming this mortality.

One of the favorite themes throughout history in religion, literature, and art has been the theme of immortality or the escape from death and the extension of one's time. The belief in life after death is based on the notion that some part of the human person, usually described as the soul, goes on for an infinite period of time. This is a quest that has produce many stories and is the basis for many systems of belief.

The fascination people have with their own mortality is not a new phenomenon. The literature of the ancient Greeks mentions it frequently. One of the most well-known scenes in ancient Greek philosophy is Socrates' deathbed speech. Most of what we know about Socrates comes from Plato's account of this speech. Stories of the River Styx and Hades illustrate the early Greek ideas of mortality and death.

In the Judeo-Christian tradition, the Hebrew scriptures provide insight into the concept of mortality as understood by the ancient Hebrews, whose focus was very much on this world; little is said about the notion of an afterlife. A similar outlook underlies many of the beliefs and practices found in modern Judaism. With the advent of Christianity, however, ideas of the afterlife took on greater importance. Islam, which shares the Abrahamic tradition with Judaism and Christianity, also finds the basis of some of its beliefs about an afterlife in these early traditions.

In the Asian religious and philosophical traditions, reincarnation is a concept that takes on major importance; to be reincarnated is seen as a form of prolonging life, but in Hinduism and Buddhism, the cycle of endless reincarnation is understood as a form of bondage that the enlightened hope to escape into a state of nonbeing, thus attaining true immortality.

In popular culture, a continuing fascination with mortality and the human desire to escape the finality of death manifests itself in the current interests in ghosts, mediums, and other psychic phenomena. In an age when tangible evidence is often needed for people to believe in something, some are trying to find tangible evidence to prove the existence of life beyond death.

Science, too, is subject to a concern with mortality and the search for ways to overcome it. Studies in genetics have made some previously fatal diseases treatable. Advances in certain medical technologies have made physical life sustainable in cases where it previously would not have been. This has given rise to the debate over exactly what constitutes life.

In the health care and insurance industries, mortality usually refers to the measurement of life expectancy. Mortality rates, which assess the frequency of death occurring annually in a given population, have declined substantially over the last century in many countries because of progress in science, medicine, and sanitation.

Moses

Moses is the most prominent figure in the Hebrew Bible, or Pentateuch. He is noted for receiving the law from God and for leading the Israelites out of bondage in Egypt to the promised land. Being such a pivotal figure, Moses plays an important role in later Jewish, Christian, and Islamic traditions. Through the centuries, Moses has been a prominent subject in art, literature, and, in modern times, film; even, most recently, as a toy action figure based on the young Moses as depicted in an animated movie.

Moses's life as described in the Bible is fairly straightforward. He was a Hebrew born in Egypt, raised by the pharaoh's daughter, and trained in the Egyptian court. Following an incident in which he killed an Egyptian who was abusing a Hebrew slave, Moses fled for his life toward Midian, where he lived 40 years. Moses received a calling to deliver the enslaved Israelites when he encountered God at a burning bush at Mt. Sinai. Upon returning to Egypt, he had several confrontations with an unnamed pharaoh accompanied by a series of

Iconic figure of Moses holding tablets with the Ten Commandments and a short staff.

divine signs and increasingly severe plagues. Finally, after the deaths of Egypt's first born, the pharaoh allowed Moses and the Israelites to leave Egypt. After a few setbacks, these people reached Mt. Sinai, where Moses met God on the mountain and received the law. Moses spent the rest of his life (about 40 years) wandering in the wilderness with the Israelites, dealing with their stubbornness and sins. After appointing Joshua to succeed him, Moses died on Mt. Horeb at the edge of the Promised Land.

Postbiblical Jewish sources depict Moses as lawgiver, prophet, priest, inventor, philosopher, holy man, and paradigm of a king. Both Philo and Josephus use the exploits of Moses to convince their audience of the viability of the history of the Jews. Artapanus, a 2nd-century BCE Jewish writer, claims Moses led an Egyptian military campaign against Ethiopia, where he won many great battles. Further, he says, Moses introduced the custom of circumcision to Egypt. Other Jewish writers wrote books containing Mosaic legends, such as the *Testament of Moses* and the *Assumption of Moses*. The book of *Jubilees* recounts the events of Genesis 1 to Exodus 12 and adds additional revelations of God to Moses.

Christian sources emphasize Moses's role as lawgiver and as a significant historical figure. He appears at the transfiguration of Jesus along with Elijah (Matt. 17:3ff.) representing the most significant persons in Jewish history. The writer of Jude adds to the Mosaic tradition by telling of a dispute between the Archangel Michael and Satan over the body of Moses after his death (Jude 9). Islamic sources treat Moses in a manner similar to that of the Hebrew Bible; however, it is in his role as a prophet that he is most often mentioned.

The portrayal of Moses in Roman sources is mixed. Generally, he is rendered as the Jewish lawgiver; however, writers like Manetho, Tacitus, and Quintilian blame Moses for teaching practices that go against civilization. Strabo wrote that Moses taught against making any kind of image of God, asserting that Moses left Egypt because the Egyptians made images of their gods.

Moses has been the frequent subject of western art, appearing in many paintings, sculptures, and stained-glass windows. In 1515, Michelangelo completed a marble statue of a seated Moses wearing horns, a pictorial convention now understood to be based on a mistranslation from the Hebrew phrase meaning "radiated light." This statue is the centerpiece for the tomb of Julius II. Moses has been the subject of several modern biographies and scholarly works, most notably Sigmund Freud's 1937 study *Moses and Monotheism*. Interestingly, Freud acknowledges that he was strongly influenced by Michelangelo's statue, which he viewed with fascination during a visit in Rome. In popular culture, Moses has been depicted in several movies, from Cecil B. DeMille's 1923 silent film *The Ten Commandments* to the 1998 animated feature *Prince of Egypt*. In the public imagination, however, the character of Moses is perhaps best known from the actor Charlton Heston's stoic and commanding portrayal in DeMille's 1956 remake of *The Ten Commandments*.

MULTIVERSES

The idea of multiple universes, or parallel universes that exist next to our own universe, has been discussed by physicists, cosmologists, and philosophers. Many different approaches and theories have been developed to consider the nature of such universes within a physical framework. If such multiverses do exist beyond our own, then one can easily imagine that the element of time could be very different in other universes.

One important theory is based on the picture of cosmic inflation. The idea of cosmic inflation, introduced by physicist Alan Guth at the beginning of the 1980s, describes a phase of rapid expansion of the universe in its very early stages. The concept behind this scenario is that the tension of the vacuum manifests itself in a repulsive gravitational force, and as a result the universe is blown up like a balloon. In more detail, a transition between different vacuum states, starting from a state with repulsive gravity and passing over to its state today, marks the beginning and end of inflation, while the vacuum energy is being released into a hot fireball of particles. After this, the normal cosmological evolution takes place. This so-called vacuum decay is not simultaneous for the overall universe as a result of quantum fluctuations during the decay process. This means that some regions have not yet reached the end of inflation, while others including our own have, resulting in island universes that can also be pictured as bubbles. This process is called eternal inflation and has been studied in detail by Alex Vilenkin; similar approaches also based on inflation have been proposed and discussed by Andrei Linde.

These island universes can be viewed as multiple universes, each following its own laws with its own time. A single universe has its own timeline, completely independent of any neighboring universe. It is possible to define a general "time" that includes all universes, although there are still problems in making any direct predictions. Such island universes can be completely different from our universe or be similar. An infinite number of such universes may exist, and it is possible that elsewhere our universe is repeated, complete with exact copies of ourselves!

Another possibility to describe and interpret multiverses comes from quantum mechanics (QM). Here, the many-worlds view of Hugh Everett and the so-called Copenhagen interpretation are two heavily discussed topics. In QM, any observable values (e.g., a subatomic particle's position and velocity) cannot be measured simultaneously, as stated in the well-known uncertainty principle of physicist Werner Heisenberg. This view is completely at variance with our common experience. In the quantum mechanical world, however, a physical object like an electron can occupy only states that have defined values (eigenvalues) with a certain probability. This probability is described by a wavefunction. Any measurement influences the system, thereby forcing the electron into one of the defined states (wavefunction collapse). In the many-worlds interpretation, the ensemble of possible states represents different universes. This means, if we measure that the electron is located in state A, it will be in state B in another universe. Note that all possible outcomes happen at the same time. Put most simply, one could say that any measurement leads to a number of universes presented by the different possible states.

The Copenhagen interpretation differs from the many-worlds view. Here, a measurement is taken over all possible universes (with different timelines), where we find ourselves in a universe with a high probability.

Many other theories have been proposed, some perhaps more plausible than others, regarding this fascinating subject. For now, all are necessarily consigned to the realm of speculation until such time as we gain the ability to test them by direct measurements.

MUMMIES

A mummy is the corpse of a human being or animal whose soft tissue has been preserved by either accidental or intentional exposure to airlessness, chemicals, extreme cold, or very low humidity. The presence of any of these conditions halts the growth of bacteria and fungi that would normally cause decay. Mummification freezes a moment in time, giving scientists a unique look at aspects of a culture that existed centuries or millennia earlier. Some mummies are so well preserved that autopsies could be performed on them. Details of diet, dress, hairstyle, tattooing, and more can be witnessed in their original context.

The English word mummy is derived from the Latin *mumia,* which was borrowed from the Arabic *mumiyyah* (bitumen). The Arabic word was also borrowed, from the Persian word *mumiyá,* which also means bitumen. Because unwrapped mummies had blackened skin, it was believed that bitumen, a black, tarry substance that seeps from cracks in the earth naturally in various locations in the Middle East, was used in embalming procedures by ancient Egyptians. Bitumen was widely used for a variety of medical applications in ancient times, so this was not an unreasonable assumption. However, the discoloration was actually caused by resins, used to prepare the body, that blackened over time.

Spontaneous mummification occurs when natural environmental conditions cause preservation without human intervention. It is rare, because very specific conditions are required. Better-known examples include Otzi the Iceman frozen in an Alpine glacier, bog people dumped in the peat bogs of northern Europe where acid and airlessness preserved soft tissue, the Greenland mummies preserved by cold and dry winds, and mummies from deserts in Chile and Egypt where heat and aridity preserved human and animal remains.

In anthropogenic mummification, humans deliberately halt the process of decay for a purpose. Examples of deliberate mummification have been discovered on every inhabited continent on Earth. While ancient Egyptians are the best known for making mummies, they were not the first to do so. The Chinchorros, a sophisticated culture occupying the northern coast of Chile, were embalming and reassembling their dead 7,000 years ago. Further to the north, the Incas used naturally occurring salts and the cold dry air of the region to preserve their mummy bundles. Human sacrifices left for the gods in caves on Andean mountaintops also were mummified in the cold, dry air. The Aleuts off the coast of Alaska processed bodies and dried them in the open air before placing them in caves. Island natives in the South Pacific smoke-cured their dead, covered them with clay, and displayed them in their villages.

Different cultures practiced mummification for different reasons. Some societies believed a person's spirit remains near after death. Mummification would pacify the spirit, hasten it along on its journey, or keep the spirit near for consultation. The preservation of enemies killed in battle gave status to the victor or filled them with the strength of those that perished. Mummification of leaders in some cultures linked the ruler to the gods and made them immortal. Animals would be mummified for use in rituals or to appease the spirit of prey after a successful hunt.

In most cases, mummification was an expensive endeavor, requiring a significant investment of time, effort, and materials. However varied the reasons for intentional mummification among the cultures of the world, the practice illustrates the power of motivation and the desire to endure through time.

MUSEUMS

All museums can be said to have a common origin in certain institutions that began many centuries ago. Whether identifying when a historic event took place, when a species became extinct, or when an art form was popular, museums share a common theme that underlies their particular mission: namely, understanding changes to human, animal, plant, and inorganic artifacts that occurred through time.

The development of museums occurred over millennia, with the first museums originating in Old World nations nearly 2,300 years ago. The earliest forms, such as the Mouseion of Alexandria (Egypt), were sanctuaries that housed a multitude of collections, including gardens with diverse plant species, remains of unique and common animal species, technological innovations, and miscellaneous writings. These institutions also served as centers for discourse between scholars who sought to unravel intellectual puzzles and educate others. Additional museumlike institutions existed in areas of Asia, Africa, and Europe, but many were simply private gatherings of antiquities, far removed from the complex structure of the museums of today and from the view of the general populace.

Private collections remained a major source of collected antiquities until the spoils of war and discoveries of New World voyages, gathered by explorers and military commanders, made their way to Europe to be housed and displayed in museums developed to serve national interests during the 17th, 18th, and 19th centuries. These institutions, developed as part of universities and as individual establishments, included the Louvre in Paris and the British Museum in London and established the practice of exhibiting botanical, zoological, library, art, and other miscellaneous collections. American museums originated during the 18th and 19th centuries, focusing chiefly on natural and local history. By the early 20th century, these institutions were often supported by funds and collections provided by patrons who traveled the world and then donated antiquities they collected in their travels, including religious paraphernalia, paintings, sculptures, coinage, human remains, and ancient weaponry. Some of the unique items brought to the United States during this time included mummies from Egypt, coins of the Roman Empire, Japanese *katanas,* and paintings created by some of the world's most celebrated artists.

In the mid-20th century, museums collectively started to receive new sources of funding, such as grants from government and private endowments, and began to expand their missions to include more systematic exploration of their own existing collections. While a number of museums had devoted efforts to understanding collections throughout history, it was during the 20th century that a widespread reevaluation and modification of museums' research activities took place. These activities led to a deeper commitment to understanding the development of humanity and specific societies through time as well as an analysis of emerging technologies. It is to all these predecessors that contemporary museums owe their existence, public support, and direction.

Each type of museum has different temporal concentrations integrated into their missions and, consequently, their collections. History museums and historical societies are among the prevalent museum types found today and have one of the most uncomplicated focuses on time. Although history museums and historical societies exist that have a world focus in their mission, most museums of this kind concentrate their collection, research, and exhibit practices on their own locality, whether it be a town, city, state, or province. These institutions seek to acquire artifacts and oral history documenting the history of their respective regions, often collecting materials connected to events or people that significantly influenced the course of that society's history. In recent years, history museums and historical societies have placed particular importance on exhibiting the genealogy of families that most affected a region's history and materials documenting the contributions to the society of different ethnic populations through time.

Art museums, meanwhile, concentrate on the collection of works including paintings, sculptures, and print media that document the different historical styles of art. The foci of exhibits in such institutions may be on art techniques (e.g., Cubism or Impressionism), individual artists (e.g., Michelangelo or Picasso), or regions (e.g., Native American art of the Southwest). Whatever the art form highlighted, exhibits usually emphasize time, whether it be the duration of popularity of an art technique or the life of an influential artist.

Science museums and centers place emphasis on innovative technologies while also exploring scientific discoveries, particularly through the fields of archaeology, astronomy, paleontology, and zoology. Science museums and centers place a special focus on the emergence and evolution of individual animal and plant species, animal orders, planetary bodies, and the universe itself. In regard to technological advances, science museums often assess specific technologies and their impact on society, examining what technologies such innovations replaced, and industry progress through time.

Natural history museums are primarily concerned with organisms and their development over time. Such institutions vary in their exhibits, collections, and research goals, which may include understanding and illustrating life forms both in stasis and within an evolutionary context.

Ultimately, all kinds of museums—whether a history museum collecting art created by local artists, a natural history museum displaying watercolor renderings of birds, or a science museum exploring the evolution of dinosaurs through a virtual exhibit—share common collection goals. Museums also show a tendency to amass artifacts or whole collections outside their mandates. That said, all museums place an emphasis on time in their own research, within their exhibit designs, and when educating visitors to their institutions.

Music

Many scholars regard music as the most important of all temporal arts. In ancient Greece music was called *μουσική τέχνη*—the art of the muses, or music drama, as it consisted in a combination of dance, singing, and instrumental music. The word *music* can still refer to musical genres like opera or music drama. There are, however, scholars who employ the notion "music" to refer solely to instrumental, or absolute music. For two reasons, a wider notion of music will be used in this entry, one that includes not only instrumental but also noninstrumental music. First, operas, musicals, and songs are usually referred to as music. Second, the etymology of the word *music* is such that the word has usually been connected with a broad meaning.

If they wish to define what music is in a short and specific phrase, scholars have to face many problems, as there are always musical pieces that are clearly musical but that do not correspond to the definition given. On the other hand, if they put forward a wider definition, it is usually the case that too many examples are included. Are bird songs music? The safest way to define music is to hold that music is everything that experts such as composers, musicologists, or music critics regard as music.

A central idea about music is that it is a temporal art, which implies that music needs to be performed in order for it to exist. All arts that need to be performed for their realization are temporal arts. Drama is a temporal art based upon a text, dance is one based upon corporal movement, and music is one based upon sounds. In temporal arts, an interplay between objective, intersubjective, and subjective time exists. Objective time refers to the time from God's perspective or from the perspective of an eternal realm of ideas in which musical works might exist. The existence of objective time can certainly be doubted.

Intersubjective time, on the other hand, is the time a watch tells us. This kind of time is based upon an interhuman agreement concerning the duration of intervals and how we calculate the duration of time. Human beings agreed to relate time to contingent natural constants like the period of time taken by the earth turning around the sun or the moon turning around the earth. Intersubjective time can be found on musical scores as *tempo,* which is discussed later in this entry.

Another type of time relevant for temporal arts is subjective time. Subjective time depends on our perception of something. If we perceive a musical piece as boring, instants seem to have a longer duration than when we regard the music as entertaining. Another kind of subjective time is related to the stage of life in which the maker or the listener happens to be. Human interests differ significantly between, say, a teenager and an adult in midlife. Concerning the difference between music makers and listeners, some distinctions need to be presented. In the case of music, there are makers of various orders. The first-order maker is often the composer who is responsible for the score. The score needs to be read and interpreted directly by the makers of the second order, whether musicians or a conductor. If the conductor is on the second level, then on the third order would be musicians. Even though the maker of the first order creates the music, the maker of the third order performs it and enables the audience, the receivers of music, to listen to it.

The following section presents some definitions of musical terms concerning the relationship between music and time, such as tempo, meter, and rhythm. Next follows a description of what the philosophers Plato and Schopenhauer put forward concerning the relationship between words and rhythm. Third is a short summary of the history of rhythm in music, and finally comes a discussion of the importance of time for the concept of the musical work.

Musical Notions and Time

Tempo

The *tempo* (plural form *tempi;* Italian for time; from the Latin word *tempus*) determines the basic pulse of the musical piece. Traditionally the tempi were described as follows (from slow to fast): *grave, largo, larghetto, lento, adagio, andante, andantino, moderato, allegretto, allegro, vivace, vivacissimo, presto, prestissimo.* When adjectives are added, the descriptions of the tempi became more precise, for example, *ma non troppo* (but not too much), *con fuoco* (fiery), and *molto* (much). In addition, there are terms specifying the change of tempo. If the tempo is supposed to become faster, the following expressions can be used: *accelerando, stringendo, piu mosso, poco piu.* If the tempo is supposed to become slower, the following expressions can be used: *poco meno, piu lento, calando, allargando, rallentando, ritardando, ritenuto.* Even though most of the time Italian tempo markings have been used, they can also turn up in French, German, or English.

By using words to specify the tempo of a musical piece, the subjective understanding of the respective notions of musicians, conductors, and the composer of a piece become more relevant. In order to fix the tempi, the metronome was invented. By means of the metronome, musical time is related to intersubjective time so that the tempo of a musical piece is specified by clarifying the amount of beats per minute (BPM). As minutes are defined on the basis of a human decision, the tempo of a musical piece that is specified by means of a description of beats per minute includes a relationship between musical and intersubjective time.

Meter and Rhythm

There are two further terms that are important for the temporal structure of a musical piece: meter and rhythm. The musical term *meter* (*μετρον*; ancient Greek for *measure*) is used to describe the organization of beats within a regular pattern. One single entity of such a pattern is called a *bar.* A *beat,* on the other hand, is the basic temporal unit of a piece—it is a type of pulse that may or may not be heard.

The specific temporal organization of a musical piece is referred to as *rhythm* (*ῥυθμός* ancient Greek for *flow*). The surface structure of a piece, which is called meter, is more constant and regular than the rhythm. However, meter and rhythm are not independent of one another. There are several theories that try to describe their relationship. It can be the case that both meter and rhythm are something similar, that rhythm is subordinate to meter, as rhythm is a meter come alive or that meter is regulated rhythm, which implies that it is a basic structure necessary for rhythm taking its proper shape.

Rhythm and Words

There are several possibilities for how rhythm can come about. In the history of music philosophy, two positions concerning the relationship between rhythm and words have been dominant. On the one hand, there is Plato's position. He defends the superiority of words over sound. His position had an enormous influence on the Florentine Camerata, whose members invented the opera genre. A similar position was also put forward by the composer Richard Wagner in *Opera and Drama*. On the other hand are thinkers like Immanuel Kant and Arthur Schopenhauer, who defend the superiority of sound over words. Concerning other musical aesthetic questions, such as that of the effect of music, those thinkers disagree significantly. Kant stresses the pleasure music provides listeners, whereas Schopenhauer regards the brief liberation from the personal will as the most important effect of great music. A more permanent kind of salvation can only be reached by means of asceticism, according to Schopenhauer.

According to Plato, a song (*melos*) consists of word (*logos*), harmony (*harmonia*) and rhythm (*rythmos*), whereby the word is supposed to be fundamental; that is, rhythm and harmony are supposed to follow the words, because words specify the content of a musical piece. Without words we would not understand the piece and would not know what it is about. It is important that we know what it is about, because music is supposed to convey the idea of the good, and only if words are at the basis of a song can it fulfill this task.

Even though Schopenhauer's philosophy of art includes many Platonic elements, he disagrees with Plato concerning the relationship of words and melody. According to Plato, words come first and determine harmony and rhythm. According to Schopenhauer, the instrumental sounds come first. The genius composer transcends the personal will and gets an understanding of the will in itself, which can directly be represented in the artistic genre of instrumental music. In order for music to have the highest kind of quality, the laws of instrumental music have to be dominant, and the words simply have to follow those laws as in the case of the composition of an opera. Here the aesthetic laws of sounds are supposed to be responsible for rhythm, melody, and harmony.

History of Rhythm

Rhythm has been dealt with theoretically as well as practically since antiquity. This entry provides a summary of the history of rhythm since the baroque era, because the history of music from that time onward includes most of the music we still listen to today. A significant notion in baroque music is the "monody," which then meant music for one voice which is accompanied with chords. The words of the one voice were supposed to bring about the sounds and with it the rhythm. The monody became popular together with the invention of the music drama by the Florentine Camerata at the end of the 16th century. Instead of simply entertaining the audience, music was also supposed to convey values. The members of the Florentine Camerata thought that music can achieve this best by means of the monody. They were inspired by a reading of ancient texts on philosophy of music, especially Plato. It was their intention to revitalize ancient Greek tragedies. They believed that ancient dramas were sung from beginning to end, a concept that scholars now regard as false. As a consequence, the opera genre was invented. Another important aspect of baroque music is its dancelike character. Hence, the general rhythmical stream was more important than each single beat, which had to be embedded in the general, overall structure.

In classical and romantic music, however, the rhythmic aspect within music became more complex. The tension between musical periods and meter became stronger. The meter of a musical piece represented its body, but the rhythm was an expression of the human spirit. Consequently, the rhythm was supposed to represent and deal with the variety of affects that human beings can have. Music was therefore far less schematic than in the baroque era. A particularly impressive representative of that period is Richard Wagner. He developed the concept of the "infinite melody," whereby rhythm also developed into something undetermined and unlimited.

In contemporary music we find an immense variety of rhythmic concepts. According to Adorno, one can distinguish two traditions within 20th-century music. The first is the avant-garde tradition, which is associated with Schoenberg. Various concepts of musical time turn up in this tradition. Here Luigi Nono has to be mentioned, because some of his scores contain no bars. The second is the neoclassical tradition, to which Stravinsky belongs; it consists mostly of linear music in which the rhythmic element is similar to that of 18th-century music, as often the rhythmical figures remain constant throughout a movement. Bartok is another composer who is representative of this tradition.

One might wish to add a third tradition to which one could refer as the postmodern one. It unites elements from various cultures and plays with these elements. The most important postmodern musical movement is called minimal music, and its leading representatives are Philip Glass and Michael Nyman. It is mostly tonal music based on simple harmonies. Of particular importance is the rhythmic element. Very often a type of polyrhythm is used, which means that various rhythms overlap. Polyrhythmic elements are usually associated with jazz and have their origins in African and Indian music. In minimal music, a simple pattern is repeated very often, whereby only simple variations occur. A piece of minimal music is in many cases constituted by uniting various such patterns and variations. Once a pattern is played at a different speed, phase shifting or phasing occurs.

Many non-Western traditions of music are even more challenging concerning the variety of rhythms. Within the Chinese, Japanese, Indian, and African traditions, irrational and polyrhythmic patterns were developed that have recently had an impact on Western minimal music. In India, the *talas* are of particular interest in this respect, as talas are rhythmical patterns that determine a composition of classical Indian music. The tempo of most talas, which are the basis of their classical compositions, can vary.

Musical Works and Time

In musicology one distinguishes between musical works and other musical pieces. A musical work is determined by means of the following qualities: it is autonomous, original, and unchangeable; was created by one composer who is regarded as its origin; is the center of attention when it is being performed; and was created for eternity.

When musical works first came about is a matter of controversy. Some scholars think that the beginning of the musical work is connected to the first formulation of the concept, which was done in the 16th century. Then Nicolaus Listenius used the phrase *opus perfectum et absolutum*. However, many scholars regard the beginning of the musical work tradition as related to its historical representation, and most scholars agree that around 1800 the tradition of the musical work became particularly strong.

There are various reasons for this position: First, before 1800, music was performed on the occasion for which it was written. From then on, older music was performed again; for example, in 1829, more than 100 years after its first performance, Bach's "St. Mathew Passion" was performed again. Second, before 1800, composers were considered not very important, but the occasion for which a piece was written or the person for whom it was composed was of significance. From 1800 onward, for at least 150 years, musical works were the dominant kind of music. After 1950 music became extremely diverse. Musical pieces were composed that were heteronomous (John Taverner, Arvo Pärt) or involved chance elements (John Cage, Iannis Xenakis), which cannot therefore be regarded as proper musical works. Most composers in the Western tradition before 1800 composed heteronomous music. Their music was created for a particular purpose, such as a coronation or a specific religious or royal celebration. These musical pieces were usually performed solely at the event for which they were made. The composition of a musical piece was, therefore, mostly related to a specific contemporary event in the here and now.

Autonomous music, on the other hand, is usually composed for eternity. Composers are sometimes seen as geniuses who manage to put together eternal music, maybe even by having access to an eternal realm themselves. What makes this music autonomous is that the music comes about via a composer who decides for himself which pieces he wishes to realize and which not. Antonio Vivaldi is an exemplary composer of heteronomous music who clearly did not write musical works; he composed about 300 concerts that all sound fairly similar. When he was alive this was not a problem, because then musical pieces were supposed to represent the type to which they belong in an exemplary matter, which is what his pieces did. A musical work, on the other hand, represents a specific solution to a detailed aesthetic problem. In the 20th century the development went so far that many works represent a type of music in itself.

Another aspect of a musical work is that it is original and unchangeable. After it has been created, it remains identical with itself. Iannis Xenakis, however, composed stochastic music, which means that it involves chance elements. It might include the demand that the audience makes a specific sound when the conductor tells them to do so. As the size of the audience is different at each performance, it is clear that his compositions involve chance elements, which is the reason why his works are not musical works. Magical music includes the Indian *raga,* a series of notes upon which a melody of classical Indian music is founded, and the tala, which knows only some vaguely given rules on the basis of which one has to improvise. As improvised music is not eternally fixed, such musical pieces are by definition not musical works. Until the 19th century, German folk songs (*Volksmusik*) were such as to enable people to have a pleasant or cozy evening together, and they were not written by a single composer. Both are reasons for their not being considered musical works.

The musical work represents a means of uniting objective, intersubjective, and subjective time. The composer grasps eternal music (objective time) and puts it together in a score so that it can be performed (intersubjective time), and listened to (subjective time). In any case, the relationship between music and time is a complex one, and it also has to be stressed that this relationship has been neglected by many modern and postmodern musicologists and philosophers of music.

Mysticism

Mysticism is a type of religious experience or altered state of consciousness in which a person senses intimacy or union with the source or ground of ultimate reality. Mystical states or experiences are qualitatively different from normal, everyday consciousness. They can be experienced variously as a vision, an ecstatic state, an emptying or silencing of the self, union with God, or absorption into God.

For the monotheistic Western religions, mysticism exists as a movement or school of thought within the religious tradition. For the Eastern world religions, mysticism is the central practice and goal. Mysticism is also a central aspect of primal religions such as shamanism. Some people without an explicit religious attachment also testify to personal mystical experiences; these include Aldous Huxley, Walt Whitman, Carl Jung, and Simone Weil.

Eastern forms of mysticism are directly related to the concept of time. For example, Hindus believe in an endless cycle of death and rebirth called *samsara.* Through the discipline of yoga, one can obtain *Samadhi,* the highest level of spiritual perfection. Through the resulting union of *Atman* (the essential self) with *Brahman* (that which is truly real), one experiences liberation (*moksa*) from *samsara.*

The Western religions of Judaism, Christianity, and Islam do not share the Eastern view of the reincarnation or transmigration of the soul, so they do not seek release from this cycle into a state of existence outside of space and time. However, many thinkers in these religions view God as existing outside of space and time. Therefore, when devotees experience mystical union with God, they often report sensations of the absence of space and time.

The adjective "mystical" (*mustikos*) was used by Christians from the 2nd century onward, but the noun "mysticism" was first used in French (*la mystique*) in the 17th century. Because it is a relatively new term, attempts to define it have varied greatly. The term can be defined broadly as consciousness of the immediate or direct presence of God (which many have claimed to experience). This broad definition would identify mysticism with spirituality or religion in general. It can also be defined narrowly as a union of the self with God or absorption of the self in the Absolute (which few have claimed to experience).

One of the most notable attempts to describe mysticism was William James's list of four characteristics of mystical experiences. First, they are ineffable: Mystics struggle to put their experience into words. Second, they are noetic: Insights gained from the experience inform a person's knowledge and understanding. Third, they are passive: They are experienced as an undeserved gift. Fourth, they are transient: Mystical experiences usually last for a short period of time. The last characteristic has proved to be less convincing to students of mysticism than the first three.

Religious traditions of mysticism have developed practices and disciplines that enable a person to achieve a state of mystical union. They provide systems of initiation and apprenticeship to inculcate mystical values and disciplines. Central to most mystical systems are the practices of meditation and contemplation, which are distinguished from each other in most traditions. In meditation, a person focuses attention and imagination on a religious idea or image. In contemplation, a person suspends the activity of the body and the thought processes of the mind in order to center the spirit on the presence of God. Meditation would be more closely associated with kataphatic mysticism, which utilizes images in order to experience intimacy with God. Contemplation is associated more closely with apophatic mysticism in which the union of the self with God is experienced as negation or absence. The terms *extrovertive* and *introvertive* mysticism are sometimes used to describe similar phenomena.

The mystical traditions in various religions reveal a diversity of practices and goals but also some similarities. Students of mysticism tend to emphasize either the common core found in all mystical traditions (e.g., Walter Stace) or the irreducible differences among them (e.g., R. C. Zaehner). Hindus practice various forms of yoga through which the conscious and the subconscious are mastered by means of moral, physical, respiratory, and mental discipline. In Zen Buddhism, the practitioner contemplates a nonsensical *koan* in order to free the spirit from the domination of the conscious mind. In Kabbalah, adherents mentally manipulate numbers and images in order to annihilate the ego, detach themselves from the physical world, and experience the presence of God directly. Christian mystics have relied upon contemplative prayer, fasting, solitude, and other forms of asceticism in order to focus the mind and spirit on the presence of God within the person. Sufi Muslims practice fasting, sleep deprivation, vigils, dancing, chanting, and contemplation to achieve annihilation of the self.

Mystical elements were present in the teachings of Plato. Centuries later, these were developed more fully by Plotinus, the founder of Neoplatonism, and his later follower Proclus. Plotinus taught that the soul must lose its present identity in order to find a transcendent self in the One or the First Principle. Neoplatonism was a major influence on mystical traditions in Judaism, Christianity, and Islam.

Mystical elements were present from the very beginnings of Christianity in the teachings and practices of both Jesus and Paul. The first Christian theologian to develop fully a theory of mysticism was Origen in the 3rd century, which led to the development of monasticism in the 4th century. Christian mystics have often spoken of three stages on the way to the vision of God: (1) purgation, which is a purification of the flesh and soul brought about through ascetic disciplines such as prayer, fasting, and almsgiving; (2) illumination, which is an enlightenment of the mind by the Holy Spirit; and (3) contemplation or union, which is an unadulterated awareness of the love of God.

Following John of the Cross, some mystical writers have identified a "dark night of the soul" that occurs before the final stage of union is reached. Notable Christian mystics through the centuries include Evagrius, Gregory of Nyssa, Pseudo-Dionysius, Augustine, Gregory the Great, William of Saint Thierry, Bernard of Clairvaux, Bonaventure, Marguerite Porete, Meister Eckhart, Henry Suso, John Tauler, Jan van Ruusbroec, Richard Rolle, Catherine of Siena, Julian of Norwich, Ignatius of Loyola, Teresa of Avila, John of the Cross, Jeanne Guyon, Emanuel Swedenborg, Thérèse de Lisieux, Thomas Merton, Karl Rahner, and John Main.

Some Christian mystics have offered theological and philosophical speculations on the nature of time. In Augustine's view, time was created by God, and it flows from the future into the present and recedes into nonexistence. One may access fleetingly and fragmentarily the experience of timeless eternity by means of a "rare vision" of enlightenment. These experiences result from withdrawal from the sensory world, an interior movement into the depths of the soul, and a movement above the soul to the vision of God. Meister Eckhart taught that the soul must look outside space and time in order to know God, because God exists outside of space and time. Giordano Bruno's mystical reflections on the heliocentrism of Copernicus led him to propose that both space and time were infinite, without beginning or end. Miguel de Unamuno y Jugo posited that the conflict between reason and the desire for human immortality gives rise to the need for faith in God. Pierre Teilhard de Chardin taught that the perfection of humanity through the evolutionary process will culminate in an Omega Point in the future.

Sufi mystics promote the role of single-minded love in the pursuit of God. Two crucial stages on the Sufi path are fana' and baqa'. *Fana'* ("passing away") is the annihilation or nullification of the ego in the presence of the divine, and *baqa'* ("subsisting") is subsisting in the divine reality, which is all that remains. In Iran, the development of the dervish as a method of achieving mystical trance popularized mysticism among all levels of the population. Some of the notable Sufi mystics are Ja'far as-Sadiq, Rabi'ah, Ibn Mansur al-Hallaj, Abu Yazid al-Bistami, Abu al-Qasim al-Junayd, Abu Hamid al-Ghazali, Ibn al-Farid, Ibn al-'Arabi, and Jalal al-Din Rumi.

Through the centuries, Judaism has produced various forms of mysticism. The earliest form of Jewish mysticism is found in Merkabah literature, written between the 2nd and 10th centuries. It promoted meditation on Ezekiel's vision of the heavenly throne room of God so that the seer might ascend through the various levels of heaven (*hekhalot*) until he arrived at the highest heaven where God dwells. Hasidism originated in eastern Europe in the 12th century. Kabbalah mysticism originated in Spain in the 13th century and was spread to the rest of the Jewish world when the Jews were expelled in 1492. Its most notable document was the *Zohar.* A new Hasidism arose in eastern Europe in the 18th century. Important figures in Jewish mysticism are Abraham ibn Ezra, Moses ben Shem Tov de Leon, Isaac of Acre, Abraham Abulafia, Isaac Luria, Dov Ber, Shne'ur Zalman, Aharon Halevi Horowitz, and Nahman of Bratslav.

Psychologists and scientists have tried to explain the phenomenon of mystical experience from the perspective of their disciplines. Sigmund Freud theorized that mystical experiences were illusions caused by a neurotic desire to recapture the infantile bliss of union with the mother. Carl Jung, who described his own mystical experiences in his autobiography, explained them more positively as encounters of the individual unconscious with the archetypes of the collective unconscious. Some psychologists view them as pathological symptoms of schizophrenia, psychosis, epilepsy, or other psychological and brain disorders, but others report that people who experience mystical states possess higher-than-average levels of psychological health.

Recently, neuroscientists have conducted brain-imaging studies of people undergoing mystical experiences. These studies suggest that repetitive, rhythmic rituals deprive the brain's orientation association area of sensory and cognitive input. As a result the brain would not be able to orient the self in its spatial context or identify the boundaries of the body. The mind experiences these sensations as a spaceless and timeless void.

MYTHOLOGY

In an effort to comprehend the whole of human experience and the place of humanity in time, ancient civilizations generated myths. The Romans chronicled time as beginning with birth and culminating in death, with great emphasis placed upon the need to be "good" in order to earn eternal life. Myths, then, are largely religious in origin and function and are in fact the earliest records of history and philosophy. Interestingly, myths have been created throughout the course of human existence and have been rendered timeless because they remain an integral part of the culture that framed them. Myths may be classified as traditional stories that deal with time and eternity, nature, ancestors, heroes and heroines, supernatural beings, and the afterlife that serve as primordial types in a primitive view of the world. Myths appeal to the consciousness of a people by embodying their cultural ideals or by giving expression to deep and commonly felt emotions. These accounts relate the origin of humankind, its place in time, and a perception of both the visible and the invisible world.

Why Were Myths Created?

It is not surprising that myths evolved in primitive cultures when people were faced with impersonal, inexplicable, and sometimes awesome or violent natural phenomena and the majesty of natural wonders. In comparison to these wonders, human beings felt dwarfed and diminished. As a result, they bestowed extraordinary human traits of power and personality to those phenomena that most profoundly evoked human emotions. The beginning of time, the miracle of birth, the finality of death, and the fear of the unknown compelled early humans to create deities who presided over the celestial sphere. In time, every aspect of nature, human nature, and human life was believed to have a controlling deity.

Initially, myths of cosmogony illuminated the origin of humankind. Virtually every culture embraces a Creation myth. Myths explain the beginnings of customs, traditions, and beliefs of a given society and reinforce cultural norms and values, thereby depicting what that society regards as good or evil. Myths assist in defining human relationships with a deity or deities. Judeo-Christian-Islamic societies have established a supreme power, a father figure, whereas the Norse tradition restricts the power and purveyance of the gods. Finally, myths help to dispel the fear and uncertainty that is part of the human condition. Fear of the elements may be explained by the activities of the gods. Fear of failure is overcome by reliance on them. Fear of death is often explained as the passage or transition to another dimension or to another domain. Simply stated, myths are a symbolic representation reflecting the society that created them. Although unjustified and unjustifiable, myths take the raw edge off the surface of human existence and help human beings to make sense of a random and threatening universe.

Universal Themes

Myths are seldom simple and never irresponsible. Esoteric meanings abound, and proper study of myths requires a great store of abstruse geographical, historical, and anthropological knowledge. The stories underscore both the variety and the continuity of human nature throughout time. The abiding interest in mythology lies in its connection to human wants, needs, desires, strengths, fears, and frailties. By their nature, myths reveal the interwoven pattern of circumstances that are beyond the control of the mortal and the immortal.

A study of the world of myths imparts greater appreciation for the subtle and dramatic ways that they pervade societies and that particular myths mirror the society from which they were created. Myths are decidedly human in origin. Ironically, it is the human ability to make myths, and the very need to do so, that ultimately sets us apart from other inhabitants of the earth. Only we humans can identify our place on the eternal timeline or calculate our brief appearance in time and space as we search for significance and immortality.

Myths may be drawn from any era and any geographical area. This entry examines components of Greek and Roman mythology, Norse and Teutonic (Germanic) mythology, Asian mythology, and commonalities among these and several other cultures.

Greek Mythology

To people of Western cultures, the most familiar mythology outside of the Judeo-Christian culture is that of Greek and Roman mythology. The mythology of ancient Greece and Rome stemmed from the human desire to explain natural events, the origin of the universe, and the end of time as we know it. Our journey through time commences with birth and continues on as we experience the tribulations and celebrations of life, and it culminates with death. Time encapsulates us. The Greek myths chronicle Zeus and his brothers, Poseidon and Hades, who exacted control of the universe from their father, Cronus, and the Titans, a powerful race of giants. Cronus himself had wrenched control from his own parents, Uranus (heaven) and Gaea (earth). Great epics were recorded of war and peace and proud heroes and courageous heroines who represented the basic cultural values of the Greek people.

Men and women alternately worshipped and feared a ménage of gods and goddesses who traditionally resided on Mt. Olympus. People attributed failure and defeat to the wrath of the gods and success and victory to the grace of the gods. The most powerful of the gods and goddesses were Clotho, Lachesis, and Atropos, the goddesses of destiny. It was they who determined how long a mortal would live and how long the rule of the gods would endure. When a mortal was born, Clotho wove the thread of life. Lachesis measured its length, and Atropos cut the thread at the exact point in time that life would end. Not even Zeus could alter their timeframe.

Roman Mythology

Much of Roman mythology had its roots in Greek mythology, although Jupiter and Mars were part of the Roman tradition long before the Romans interacted with and eventually conquered the Greeks. Subsequent to 725 BCE, the Romans adopted many Greek deities, renaming them, and making them their own. In both Greek and Roman mythology, realms of the universe were delineated. They saw the cosmos in terms of the skies, the earth, the seas, and the lower world. Jupiter (Zeus) ruled the skies from atop Mt. Olympus, where he controlled the movement of the sun, the phases of the moon, and the changes of the seasons. The fairest and the wisest of all immortals, Jupiter, when outraged, hurled lightning and thunderbolts down upon the earth. Neptune (Poseidon), the second-most-powerful god, ruled the seas, and Pluto (Hades), the god of wealth, ruled the lower world.

In Roman mythology, myth and time are closely related. The Romans equate the onset of time with the birth of Rome, which is accredited to Romulus and Remus. While these two were infants, they were set afloat to die in the river by their uncle who feared that they would usurp his power. The children survived their ordeal and eventually founded the city of Rome, named after Romulus, and this founding was considered to be the advent of time. Saturn, the father of Jupiter, Neptune, and Pluto, was believed to be the god of time, birth, and death. The Romans strongly believed that living an honorable life on Earth could earn for them eternal life in heaven and possibly a place among the gods. Evildoers, unless they appeased the gods, would be damned to the underworld, where they would spend eternity. The end of time for man was marked by death and reclaimed for eternity in the afterlife.

As we read these highly entertaining and often spiritually uplifting myths, we learn a great deal about human nature and of our debt to Greek and Roman cultures. Even today, in our struggle to survive, Greek and Roman myths help people to better understand humanity's obedience to a higher power, the relationships of men and women to one another, the power of love and friendships, the horror of war and natural catastrophes, and the passage of time, with death and the afterlife to come.

Norse and Teutonic (Germanic) Mythology

Germanic mythology refers to the myths of people who spoke Germanic dialects prior to their conversion to Christianity. These ancient Germanic people from the continent and England were illiterate. Most of what we do know about the mythology and beliefs of that era comes from literary sources written in Scandinavia and then transcribed into the Old Norse language of Iceland between the 12th and 14th centuries. Two collections of verse, known as the *Eddas,* exist. The earliest, the *Elder Edda* or *Poetic Edda,* contains the earliest Norse mythology; the *Younger Edda* or *Prose Edda* was written by Snorri Sturluson about 1220 CE. In the *Prose Edda,* Sturluson combined a variety of sources with three earlier poetic accounts of the origin of the world in order to create a wholly representative mythology.

In the *Prose Edda* version of the Creation, all that originally existed was a void called Ginnungagap. There was no time, and everything remained still. To the north of the void was the icy region of Niflheim; to the south, the sunny region of Muspelheim. Warm breaths from Muspelheim melted the ice from Niflheim, and a stream of water flowed into the void from which the giant, Ymir, ancestor of the Frost Giants, emerged. Created from drops of the melting ice, Audhumbla, the cow, nourished Ymir and was nourished herself by licking salty frost- and ice-covered stones. The stones were formed into a man, Bori, who was destined to become the father of Odin, Vili, and Ve. The brothers slaughtered Ymir and created the earth from his flesh, the mountains from his bones, the sea from his blood, the clouds from his brains, and the heavens from his skull.

The heavens, according to the *Prose Edda,* were balanced by four dwarfs: Austri, Westri, Nordi, and Sudri, the directions on a compass. Sparks from the fire-land, Muspelheim, became the stars of the sky. This newly created land, named Midgard, was to become the somber home of mortal humans. Even in Asgard, home of the gods, the atmosphere was grave, and the Norsemen believed that the end of time would come in a bleak and horrible way. The only hope was to face disaster and fight the enemy bravely to earn a seat in Odin's castle, Valhalla.

As did so many similar myths, Norse mythology reflected the attitude of the culture that in death there is victory and true courage will not be defeated. The final chapter in Norse mythology is called Ragnabrok, meaning the twilight of the gods. In this period it is prophesied that winter will continue for three years. On the last day, Odin will lead dead heroes in a fierce battle against the Jotuns (trolls) and the power of darkness. Odin, himself, will be devoured by the Fenris Wolf, and the world will become a smoking ruin swallowed by the sea. From this will come new life and a time of peace.

Asian Mythology

The myths of India, China, and Japan are highly complex and sophisticated. They differ from Greek, Roman, and Germanic mythologies in that rather than venerating anthropomorphic deities, the structures of their deities are often polymorphic, intricately combining human and animal forms. The gods and goddesses of the Hindus sometimes take extraordinary human forms, with numerous heads and eyes and arms. Hindus believe that their religion existed before the universe came to be. Their mythology on the afterlife is unique. They believe in karma and reincarnation. Simply stated, karma is the effect of an individual's actions resulting in consequences in present and future lifetimes. At the time of death, to be reincarnated as a human being is thought to be a blessing. Reincarnation as an animal or a plant is reserved for those for whom a spiritual life is not possible.

Deities in Chinese and Japanese myths were also animistic, but these myths were supplanted by mythologies derived from the three great religions: Taoism, Confucianism, and Buddhism (Buddhism having been brought to China from India in 300 BCE). Shinto, the religion indigenous to Japan, borrowed much from Chinese mythology, resulting in a tradition that paralleled that of the Buddhist pantheon. Notably, in Asian cultures, two or more religions may be observed simultaneously, because they are less eschatological but more ethical or philosophical in emphasis.

Generally speaking, before there was heaven or earth, there was chaos, devoid of time, shape, or form. First to materialize was the Plain of High Heaven and the three creating deities. Earth was born, and immortals procreated. It was due to the "divine retirement" of the goddess, Izanami, that the notion of death or life limited by time entered the world. It is interesting to note that there is difficulty in finding a Chinese word equivalent to the English word "time." "Shi" can be associated with time, but the meaning tends to mean "timelessness" or "seasonality." In Asian cultures, time is marked by history, as in the duration of a dynasty. Individually, time is of little concern, because a person's life is viewed as part of an ancestral continuum. Although the tenets of these religions encompass a belief in life after death, the focus is showing people how to live rather than what will happen to them upon their demise. We may deduce, then, that oriental myths not only explain the origin of the universe and the parameters of earthly time, but they also deal with commonly held distinctive aspects and cultural values of each civilization.

In ancient times, throughout history, and even today, the family is considered to be a critical part of oriental society and culture. Honor and obedience to one's parents is related to ancestor worship. During the Han period in China, emperors set up shrines for their ancestors because they believed that spirits could bring blessings to them and to their families. In general, oriental myths connect the actions of deities and other supernatural beings to the everyday actions of men, women, and the natural world around them. Individual gods protected the family, the home, and the country and represented the sun, the moon, and the planets. Myths describe how the islands of Japan were created and deliberately located by the gods in the very center of the world. The two main books of the Shinto religion are the *Koji-ki* and the *Nihon-gi*. *Nihon-gi* explains how all of the emperors of Japan are directly descended from the sun goddess. Today, the rising sun is symbolized in the Japanese national flag.

Commonalities

What the disparate mythologies from all over the world have in common is their heartfelt desire to explain the origin of humankind and to validate its existence. We are searching to satisfy the very human need to explain our relationship with the powerful and mysterious forces that drive the universe. Throughout the world, myths reflect those themes that deal with nature, supernatural beings, ancestors, heroes and heroines, life, death, and time. In Africa, where myths have been preserved mainly through the oral tradition, the natural elements are immortalized through myths. Many versions of Creation stories abound. The Dinka of Sudan believe that the first man and woman were made from clay and put into a tiny, covered pot, where they grew to full height. Australian aboriginal mythology deems that their community and culture were created during dreamtime, "the time before time," when spirited creatures came from the sky, the sea, and the underground to generate mountains, valleys, plants, and animals. We are familiar with the great spirit myth of North American Indians and the time that Native Americans identify for their ancestors in the happy hunting ground. The Aztec people of South America were polytheistic and offered sacrifices to appease their gods. Huitzilopochtli, the great protector of the Aztecs, was portrayed in the form of an eagle, and it was he who deemed where the great pyramid would be built as "the heart of their city and the core of their vision of the universe." From Ireland comes a myth about Cu Chulainn, a hero who could change form to oppose evil forces. A Polynesian myth from the islands of the Kanaka-Maori people centers on Maui, who brought the gift of fire to his people. In ancient Egypt, from pharaohs to peasants, each individual had a god or a goddess corresponding to his or her time and place in society.

As we can perceive, in every era and in every geographical area, myths have evolved as nearly sacred literature, devoid of theology. Each myth is unique to a culture and is in itself a monument to the precariousness of human existence.

As society becomes increasingly more global and less local, people continue to find experiential concepts that are impossible to fathom and beyond human comprehension. The beginning of time, the miracle of birth, the finality of death, and the fear of the unknown compelled early humans to create deities who presided over the celestial sphere. If myths are a symbolic representation reflecting the society that created them, how, then, will the mythology of our times satisfy our collective need to know?

Nabokov, Vladimir (1899–1977)

Vladimir Vladimirovich Nabokov, a Russian author and entomologist, was born into a wealthy patrician family in St. Petersburg, Russia, and died in Montreux, Switzerland. Time plays an important role in all of Nabokov's novels, and in all of his works a certain melancholy is noticeable.

Nabokov's father, Vladimir Dimitrijevich Nabokov, was a liberal criminologist, publicist, and politician who was one of the leaders of the Constitutional Democratic Party in Russia before the Russian revolution. His mother, Jelena Ivanova Nabokov, née Rukavishnikov, came from a family of industrialists and land owners. In the Russian October Revolution of 1917, the family lost all its property. The elder Nabokov was one of the leaders in the Duma in the February Revolution, but he had to flee after being captured by the Bolshevists in the October Revolution. The family left Russia for England, where Nabokov attended Cambridge and studied Russian and French literature; later the family moved to Berlin, Germany. In 1922, while shielding a friend from gunfire, his father was assassinated at a political meeting by a reactionary Russian exile.

In 1925, Nabokov married Vera Jevsejevna Slonin, a Jewish Russian. In the same year, his first novels, *Maschenka* and *Korol, Dama, Walet* (*King, Dame, Knave*) were published. In 1937, Nabokov had to flee to France because he was married to a Jew in Germany. In Paris, he wrote his first novel in English, *The Real Life of Sebastian Knight* (1939), was published in 1941. In the same year, his mother died in Prague. In 1940, together with his family, he moved to New York shortly before France was conquered by Germany. From 1941 to 1948, he worked as a lecturer in Russian language and literature and as a research fellow in entomology at Harvard University in Cambridge, Massachusetts. From 1948 to 1959, he was a professor of Russian and European literature at Cornell University, in Ithaca, New York.

Nabokov's first autobiography was published in 1951, and it was republished after many changes as *Speak, Memory* (1966). In 1955, what was to be his most famous work, the novel *Lolita,* was published. In this novel, the cultured Frenchman Humbert Humbert writes his memoirs concerning his love for a 12-year-old American girl. The book was a succès de scandale and a literary sensation; the substantial income from this novel allowed Nabokov to quit his work as a college professor and to move back to Europe, where he and his wife lived in a suite in a hotel at Switzerland from 1961 onwards.

His second famous novel, *Pale Fire,* appeared in 1962 and consists of two parts. The first part is a poem by a fictional author called John Shade. In the second part, the scholar Kinbote, who claims to be the king of a country called Zembla, comments at length on the poem and interprets it as the story of his own life.

In his most famous novel, *Lolita,* there is the contrast between the protagonist and the narrator of the story. Both are one person: Humbert Humbert.

But, the narrator Humbert tries to relive the pleasures he once had by telling the story of his time with Lolita. The pervading melancholia results from the feeling of being small and powerless in comparison with the universal laws of time and the universe. On the other hand, time does not matter for that work of art which can revive memories (even the memories of strangers). Unfortunately, these memories are always deficient.

While Nabokov's concept of time remains implicit in his novels, it is one of the main themes in his autobiography *Speak, Memory: An Autobiography Revisited* (1966). Many of his creative ideas were inspired by his reading of Marcel Proust. Nabokov's main theme in this context is human consciousness. For him, the human life is "a brief crack of light between two eternities of darkness." But in consciousness, a human life (even other human lives) can be preserved in memories. From this viewpoint, literature is a way to preserve memories (although a deficient one) and also a way to prevent others from dying. Moments and persons can be conserved in words, but not without a loss of reality. Consequently, consciousness is superior to literature.

From Nabokov's point of view, literature is a desperate fight against time and darkness, which, in his opinion, follow the consciousness of a human life.

Nāgārjuna, Acharya (c. 150–c. 250 CE)

Mahayana Buddhist tradition attributes the founding of the Madhyamika School to Acharya Nāgārjuna (c. 150–c. 250 CE), but this attribution is probably incorrect, because there is no designation for such a school until the work of another monk named Candrakirti refers to it in the 7th century CE. Although he is credited with composing other works, Nāgārjuna's seminal text is *Fundamentals on the Middle Way,* in which he advocates a philosophy of the middle way between the extremes of being (eternalism) and nonbeing (nihilism).

This philosophical position means that nothing in the world exists absolutely and nothing perishes totally. Nāgārjuna's middle way is located beyond concepts or speech in the sense that it is transcendental. This philosophical position also means that no specific position is limitless or ultimate. In fact, the ultimate truth is that there is no correct view, final truth, or goal, because all views are flawed. Nāgārjuna's middle way implies rising above clinging to either existence or nonexistence. More precisely, the middle way is the practice of the perfection of wisdom (*prajnaparamita*), or ultimate virtue for a bodhisattva (enlightened being). When one achieves wisdom, one does not arrive at a particular type of knowledge, but one rather reaches a point at which all knowing and theorizing are terminated.

Nāgārjuna makes a distinction between two kinds of truth: conventional and ultimate. The former is valid and useful for practical living, but it is illusory, because it becomes self-contradictory if we push it too far. This is evident with the concept of time. From a conventional perspective, the concept of time represents the past, present, and future that appear as a series of moments; this is associated with human perception and conceptual formulation. The conventional concept of time is formed by the assumption of a self-substantiated reality that binds persons to their own emotional and conceptual habits. In short, for Nāgārjuna this is the realm of ignorance, which involves mistaking things or concepts for what they are not in fact, because ignorance obscures the real nature of things and constructs a false appearance.

In contrast to conventional truth, Nāgārjuna defines ultimate truth as a nondual type of knowledge that involves a contentless intuition. By viewing time from this perspective, we observe it simultaneously much as we view a painting on a wall by seeing the whole of it. This intuitive type of knowledge is beyond ordinary objective knowledge and reason, because it represents dissolution of the conceptual function of the mind, although it does not represent a total rejection of conventional truth. It is the realization that all distinctions, such as the three moments of time, are empty (*sunyata*), which is true of everything in the world.

If time and everything else in the world is empty, there can be no essential distinction between existing things. Nāgārjuna denies the distinction between self-being (*svabhava*) and other-being (*parabhava*). If self-being is the essential nature by which something is what it is and not something else, and other-being owes its existence to something else, Nāgārjuna denies that there is anything that is not dependent or conditioned. The heat of fire, for instance, is never encountered apart from fire, making heat something created and not self-existent. If the true nature of everything is emptiness, there is nothing that is self-existent, because it would have to be necessarily noncontingent and unrelated to anything else, which means that lack of self-existence is the nature of things.

These fundamental philosophical convictions motivate Nāgārjuna to criticize basic categories, such as causation, motion, and time. If all things are conditioned, each phase, for instance, possesses a before (future) and an after (past) relative to it. Using his dialectic that undermines all philosophical positions, Nāgārjuna asserts that each part of his dialectic is a counterpart to the prior step, which results in each part negating and canceling out its predecessor. Nāgārjuna's dialectic moves toward the negation of the final part. By thus disposing of all philosophical views, Nāgārjuna uses his dialectical method as a therapeutic device to cure humankind of its suffering, which is caused in part by its mental and emotional attachment to phenomenal and conceptual entities in preparation for genuine insight into the nature of things.

With respect to the notion of time, the dialectic indicates that neither the present, past, nor future can be seized as absolute, but they have significance only relative to each other. Thus the three moments of time are relational concepts. There is no such thing as the past in itself, the present in itself, or the future in itself. Moreover, time is pertinent merely to this world. If ultimate truth indicates that there is neither past, nor present, nor future, time is a derived notion or a mental construct. There are no individual entities of time.

This position means that time is not an immutable substance that can be grasped and measured. There is also no absolute time that continues to be real apart from successive moments. Time is merely a mode of reference that points to the arising and perishing of events. When a person witnesses these arising and perishing events, he or she names them "time" and draws distinctions among the moments of time in relation to each other.

From Nāgārjuna's perspective, the three moments of time enable one to grasp time as a set of relations. To be located in any particular moment—past, present, or future—means to be dependent upon the location of the other moments. Therefore, the present is, for instance, such only because it is located within the instants of the past and future, which suggests that time is a dependent set of relations among three moments. No single moment of time represents an entity in its own right.

From the perspective of attaining liberation, there is no escape from time, because there is nothing from which to escape. In the final analysis, Nāgārjuna does not deny the commonsense view of time. What he wants to show is that time and other categories are not ultimately real.

Navajo

The Navajo, or Diné (meaning "the people"), are the most numerous of the North American Indian tribes, having more than 290,000 people. The Navajo nation ("the big rez"), which is about the size of West Virginia, officially encompasses 25,000 square miles at the juncture of northeastern Arizona, southeastern Utah, and western New Mexico. The reservation itself was created in 1868 by the U.S. government; however, the Navajo live within the four sacred mountains, (Mt. Blanca, Mt. Taylor, San Francisco Peaks, and Mt. Hesperus), a place of great beauty where they feel they belong in accordance with the guidance of their holy ones. This space is actually larger than what is considered the present day reservation.

Life and time are cyclical in the Navajo cosmology, and everything has a place within it. Stories passed down in Navajo culture explain that the people emerged into this location after going on a long and arduous journey during which they passed through four different colored worlds. In the first world (black world), first man and first woman were formed. They passed through the second world (the blue world), the third world (the yellow world), and the fourth world (the glittering world). Quarreling forced them out of each world; they had encountered insect beings, several species of birds, and many mammals, including Coyote, a trickster who is an important figure in Navajo culture. The natural world was put into harmony or balance (*hozjo*) by the Creator or spiritual life force. Finally, a flood brought the Navajo to the fourth world or glittering world of the four sacred mountains. The Navajos are said to have emerged from a hole in the La Plata Mountains.

Early History

Archaeological and linguistic evidence shows that the Navajo migrated from present-day northwest Canada and Alaska to the American Southwest around 1000 CE. Linguistic similarities suggest that the Navajo and Apache tribes were once a cohesive ethnic group, speaking the dialect of the Athabaskan and Apachean language family. Navajos were considered highly adaptive to changing conditions and were able to incorporate things from other cultures. They were famously known to their Pueblo neighbors as traders and raiders. The Pueblo groups exchanged maize and woven textiles for meat and hides of deer, antelope, and elk. The Spanish arrived in the 1500s, bringing with them horses, sheep, and goats of European origin. After Spanish colonization in the 17th century, Navajo life became more sedentary as the people established camps to raise sheep and corn. They learned weaving from the Pueblos and silver crafting from their Mexican neighbors.

Shaping of the Navajo Nation

Anglo Americans and Navajos lived in relative peace during the 1800s until a Navajo leader named Narbona was killed in 1849. In the 1850s the U.S. government began to set up forts in Navajo territory, including Fort Defiance and Fort Wingate. After the Spanish were expelled by the Anglo Americans in the southwestern United States, the Navajos fell under the scrutiny of the U.S. government, which was determined to settle the West. The Treaty of 1868 is a significant event in Navajo history and Navajo/U.S. government relations. Unlike so many other Native American tribes during the 19th century, the Navajo were allowed to return to a portion of their traditional homelands. Attempts were being made to round up tribal groups in an effort to solve the "Indian problem" by creating reservations. In 1863, the dispossession of their lands was a major blow to the Navajo. The U.S. government was trying to prevent raids intertribally and on encroaching settlers. In addition, whites suspected that there were valuable minerals on Diné lands. Colonel Christopher "Kit" Carson was called in with his army to defeat the Navajo. Carson commanded his soldiers to shoot on sight men, women, and children. He also wiped out the Diné food supply, burning crops, killing domesticated animals, and torching houses. In February of 1864, the Navajo began to turn themselves in to army forts in surrender.

The policy of Indian relocation set forth by the U.S. government proved to be a disaster. The Long Walk (to Bosque Redondo) is an especially painful moment in Navajo history. The Diné were forced to walk for 3 weeks for more than 300 miles, and hundreds lost their lives. When the Navajo finally arrived at Bosque Redondo, they faced extreme living conditions. The water was unfit to drink, there was no firewood, and they were rationed poor-quality subsidized food from the U.S. government. Around 9,000 Navajos were relocated and were not allowed to return to their lands until the Treaty of 1868, which many Navajo leaders signed to recover their lands.

Navajo Family and Daily Life

The Navajo tribe is a group of more than 100 separate clans, including the four originals: Towering House, Bitterwater, Big Water, and One Who Walks Around. Families consist of extended kinship networks, with clans being traced through the mother's side ("born to"), and the father's side is acknowledged by saying "born for." Women have an important status in Navajo society. When a man gets married he joins his wife's family, and the wife's brother takes on many roles associated with fatherhood toward her children. Traditionally, marriage within clans is not permitted. Both men and women care for children. The women have land rights, in addition to owning the house, the goats, and the sheep.

When Navajos first meet each other, they state which clan they are from. *Ya'at eeh* is a common phrase, which means "greetings" in the Navajo language. Navajos live in isolation from one another on the landscape. It can be miles between two Navajo sheep camps, the land between can appear to be uninhabited. Physical and personal space is valued. It is estimated that 80% of the Navajo still speak their native language. Language, customs, and lifeways have been preserved and passed down in the Navajo culture despite strong outside Anglo influences to assimilate.

Hogans

Traditional houses are called *hogans*. The houses are eight-sided, domed, and nearly circular in shape. Old timers still use these as a dwelling, while more often in contemporary times these structures are used for ceremony. They are made of wood poles and earth with the doorway open to the east to welcome the morning sun and receive positive energy and blessings. The sun is an important symbol of the divine and Creation; however, the sun itself is not worshiped in Navajo religion. The Navajo find balance with an orientation within the four directions. East represents the dawn and thinking, south signifies planning and what needs to be done, west represents life and how to carry out plans, and north an evaluation and reflection of how to continue of the path of life. ("Before me, behind me, below me, and above me, with balance I pray" is a common morning prayer of centering along with the focus on beauty: "All is beautiful, if everything around you is beautiful, beauty is the way you live.")

Today, many hogans are constructed with modern materials and have windows. Sometimes, small hogans are built for sweat baths. The steam makes the body sweat and a cleansing occurs on both a physical and spiritual level. Additionally, some families build summer hogans and winter hogans near appropriate places where their sheep graze.

According to custom, it is considered rude to greet a person when visiting a hogan without waiting several minutes before entering. It is also considered rude to make eye contact or to shake hands with another with a firm grip. Religion is integrated into all other aspects of daily life for the Navajo. Life itself is considered sacred along with the earth and the idea of maintaining balance or harmony with all things. Life is cyclical, as well as time, and everything has a place and a season in Navajo religion and cosmology. In the Navajo culture there is no such thing as a coincidence; things happen because they were meant to. Religion ceremonies are elaborate and complex, lasting anywhere from 3 to 8 days or more. Religious gatherings include songs, chants, prayers, and sandpaintings. Ceremonies are called *Ways* and the religious leader is a *singer* who sings special songs and makes sandpaintings. Ceremonies were given to the Navajo by the holy ones, who instructed them in how to recite the prayers and songs. Important lessons have been passed down along with history and universal wisdom. Ceremonies are used for healing the sick, for blessing a person, or for celebrating a happy moment, such as the birth of a child. Corn and corn pollen are considered sacred and play an important role in Diné ceremonies. The content of ceremonies includes much sacred knowledge with great power, and parts of ceremonies remain secret and are not discussed outside the ceremony.

Sandpaintings

Sandpaintings are "a place where the gods come and go" in the Navajo language and are used in healing ceremonies and to connect with nature. These elaborate creations are filled with symbolism and often contain representations of the first man and first woman from Navajo cosmology. After the ceremony, the pictures are swept up and the sand is taken away.

Ways

There are several Way ceremonies that serve a certain purpose in Diné culture. The Night Way is a 9-day healing ceremony where friends and relatives gather around the sick person and songs, and prayers, are offered and sandpaintings are created. The enemy Way is used when a Navajo returns from a non-Navajo society to cleanse that person of foreign influences. The Blessing Way is a ceremony that is used to be sung over someone. It is unique, because it is not used for healing; rather, it is used to foster good luck, good health, and blessings relevant to a person's life.

Navajo Code Talkers

During World War II, 3,600 Diné men and 12 women entered military service. The Japanese had been able to decipher all U.S. military codes until the Navajo marines created a code in the Navajo language that was an impenetrable means of secret communication. This made the contributions of these Diné soldiers indispensable to the U.S. military. In 1982, President Ronald Reagan declared August 14th Navajo Code Talkers Day, and in July 2001, 29 code talkers were given Congressional Gold Medals.

The Navajo Today

The Navajo Nation today is a mixture of traditional and modern. There are houses and hogans, sheep farmers and engineers, silversmiths and nurses. However, much is preserved due to the organization of tribal government and Navajo schools with curriculums relevant to Navajo culture and staffed by Navajos, including Diné College. The Diné nation continues to grow and flourish in the 21st century despite some major dark points in its history. The Navajos have proven to be highly adaptable and have overcome adversities. Their determination and philosophy of life allows them to continue and to "walk in beauty."

Nebular Hypothesis

At the beginning of the 17th century, Johannes Kepler was able to illustrate that the planets tended to move elliptically. Subsequently, the publication of Isaac Newton's laws of motion and gravitation in 1687 marked the first systematic scientific approach to examining the origin of the solar system. Then, in 1755, the German philosopher Immanuel Kant proposed the theory that the solar system had its beginnings as a cloud of dispersed particles of both dust and gas and that it is a product of centrifugal and centripetal forces. In 1796, the French mathematician Marquis Pierre-Simon de Laplace refined the theory further. He described the original state of the solar system as a hot, rotating nebula. As the mass cooled and contracted, the nebula assumed a flattened shape. The sun was formed at the center, with rings of gaseous material surrounding it. Planets then condensed from the rings. By the same process, moons formed around planets. This theory seems to explain why planets generally move in the same plane and direction.

It was at this point in time that the theory first became known as the "nebular hypothesis." It has since sometimes been referred to as the Kant/Laplace nebular theory, because Kant apparently arrived independently at the modified version of the hypothesis about the same time that Laplace did so. Laplace thought that the theory supported the predictability of the universe, while Kant believed that it indicated the universe was likely to change through time.

Though the nebular hypothesis has been examined and modified through the subsequent years by the scientific community, Kant's original brilliant concept can still be said to serve as an important component of current theories on planet formation.

Early in the 20th century, several British and American scientists pointed out definite deficiencies in the nebular hypothesis and proposed that planets were formed by a rare encounter of a star and the sun. In the mid-20th century, these star encounters were shown to be impossible, as the gaseous material involved would naturally dissipate rather than condense as planets. Therefore it was generally concluded that the formation of planets and stars must take place during the same process. Scientists have indeed noted that planets tend to form around newborn stars, and they now refer to the disks of dust and gas they have observed around these stars as "protoplanetary disks."

Naturally, scientists have always been interested in determining how long it took the universe and specific planets to form. A common theory has been that there are two stages in the formation. It is during the first stage of accretion that small, rocky planets such as Earth form. Solids collide and stick together, with gases forming atmospheres around these smaller planets.

A smaller planet must have the time to grow large enough for the second stage to begin and for larger, gaseous planets to form. There is more limited opportunity for these larger planets to form, because the gas itself might disappear in a few million years. On the other hand, the formation of the smaller planets can continue more slowly for up to 10 or hundreds of million years.

It has been speculated that the disks around smaller planets disappear after 3 to 5 million years. Yet that time period may well be too limited to permit the formation of larger planets, such as Jupiter. A number of scientists now accept the theory that other solar systems with similar sized planets must be fairly common (and planets larger than Jupiter have actually been noted), but more research is needed to attempt to explain exactly how Jupiter—and all the other planets—did form.

Two theories of how the gas giants formed have been proposed. "Core accretion" would result in these giants forming relatively slowly, because a large, solid core would be necessary to attract a large quantity of gas. "Disk instability" proposes that a cold disk could break up on its own if it is cold and dense enough, resulting in gravitational abilities. The latter process could produce protoplanets in only hundreds or thousands of years.

The original concept that the nebular hypothesis involved a disk forming around a condensed center is still held regarding what is now commonly referred to as the Solar Nebula. As gas and dust collapsed toward the center, kinetic energy was formed and the temperature rose to the point of producing a nuclear reaction and the subsequent birth of the sun.

Theories have also been developed about the differences between the inner and outer planets. Their size appears to involve how much water is available and whether planets are far enough away from the sun for ice to form. Planets located at a far enough distance from the sun can acquire more solid mass and attract large amounts of many other elements, including the abundant elements hydrogen and helium. These larger planets formed beyond what is referred to as the "snow line." As is the case with many credible theories, there have been questions about whether or not this process is inevitable. Discoveries and observations of other solar systems, such as 51 Pegasi, indicate enough definite differences from our solar system to raise further questions about exactly how planets are formed.

Current efforts to verify or modify the body of knowledge about how planets are formed are employing many avenues for research. Some, such as Richard H. Durisen's attempt to update Laplace's theory, make use of computer simulations while still identifying dense gas rings as the mechanism of planet formation. Other research focuses on areas beyond our own solar system, such as the Hubble Space Telescope's production of images of protoplanetary disks around stars in the Orion Nebula—about 1,600 light-years away. Continuing observation by astronomers is likely to yield greater understanding of the process of planet formation.

Neogene

The Neogene, a term introduced by Moritz Hörnes in the mid-19th century, is a period in the geochronological scale and a system in the chronostratigraphic scale. This dual procedure (time interval and corresponding rock record) is used by earth scientists to subdivide geologic time in deciphering the history of the earth. The Neogene is the last period/system of the Cenozoic era/erathem and, accordingly, the most recent one of the earth's history. It began 23 million years ago, at the Paleogene-Neogene boundary, and it ends at the present. Under the current proposal of the International Commission on Stratigraphy, it includes four epochs/series: Miocene, Pliocene, Pleistocene, and Holocene. The classification and interpretation of the last two epochs/series, as well as a Quaternary sub-era, have been, and still are, a matter of debate. An important consequence is that the scientific community inherited different notions for the Neogene. Thus, the end of the Neogene has been variously interpreted to be at the Pleistocene–Holocene, Pliocene–Pleistocene, and Tertiary–Quaternary boundaries.

Marine microfossils are the backbone of the subdivision of the Neogene into its constituent ages/stages. Complex mammal evolution under the influence of major continental separations and climatic change and orbital forcing cyclicity in sediments and oxygen isotopes records in the Atlantic and Mediterranean (supported by the Australian–Antarctic marine magnetic polarity scale) provide a precise and highly accurate Neogene timescale.

The Neogene Earth looked much like our own. However, the relatively similar distribution of landmass between then and now masks some dramatic changes. Some continental motion took place during the Neogene, the most significant event being the counterclockwise rotation of the Arabian Plate, connecting Africa and Eurasia and cutting off the remnants of the old Tethys. India collided with Asia, giving rise to the Himalayan Mountains and the connection between North and South America.

In the south, a continuous circumpolar current circled Antarctica, isolated from other landmasses. Thus both poles were thermally isolated from warm equatorial waters, and (perhaps for the first time since the Ordovician) both poles accumulated heavy coverings of ice. At the same time, the virtual closing of east-west circulation through the Mediterranean Sea and between the Americas changed the hot, circulating currents. Thus, during the Neogene the world became much drier and cooler, culminating in the Pleistocene ice ages and the harsh conditions of the present day.

The world dried out. Huge deserts developed in North Africa and Central Asia. Grasslands expanded and quickly replaced the thinning forests. During the Neogene, birds and mammals evolved considerably, and the dawn of the genus *Homo* occurred. However, most other animals not needing grasses were relatively unchanged. Grasses are poor fodder: tough, low in nutrients, high in tooth-destroying silicates. Consequently, herbivorous species were smashed or utterly changed. Some grazer species emerged and evolved high-crown teeth. Ruminants diversified, and cranial appendages appeared. Nevertheless, their predators followed them into extinction or transformation. The later Neogene saw the creation of an entirely new type of hunter, the pursuit predator. The pursued developed their own responses: herd behaviors, seasonal migrations, and big bodies adapted for speed and endurance in open country.

Another line of adaptation led to small-bodied generalists (rodents, raccoons, rabbits, and opossums) and their predators, the foxes, cats, dogs, and snakes. These generalists were mainly unspecialized herbivores or omnivores with partially fossorial habits, strong territoriality, and high reproductive rates. Theirs was the ability to exploit many resources within small, locally, or temporarily favorable conditions.

The Miocene epoch (23 to 5.3 million years ago [mya]) or "less recent" is so called because it contains fewer modern animals than the following, Pliocene, epoch. The Miocene is the longest epoch of the Neogene. During the late Miocene the island continent of India slammed into Asia, pushing up the Himalayas. Elsewhere, the western American cordilleras, the Alps, and the Caucasus rose as well. One of the best known events in the marine realm is the Messinian salinity crisis at the end of the Miocene. The rise of mountains in the western Mediterranean combined with the global fall of sea level due to formation of the Antarctic ice cap sealed the western end of the Mediterranean for about 600,000 years. During this time, the Mediterranean Sea virtually dried up, forming enormous evaporite deposits. When the present Strait of Gibraltar was ultimately opened, the Atlantic would have poured a vast volume of water into the Mediterranean drying basin, resulting in a giant waterfall, much higher than 1,000 meters and far more powerful than Niagara Falls. On the other side of the African continent, three major rifts opened in roughly an east to west sequence. These events were probably related to the counterclockwise rotation of the Arabian plate. The Miocene was a time of warmer global climates, but during the mid-Miocene (14 mya), a marked drop in temperatures occurred and further led to the buildup of the East Antarctic ice cap.

The Miocene was a time of huge transition, the end of the ancient world, and the birth of the more recent sort of world. Two major ecosystems first appeared during the Miocene: kelp forests and grasslands. It was also the high point of the age of mammals. Also, this period saw animals that had evolved on different continents during the Eocene and Oligocene spread via land bridges.

The Pliocene epoch (5.3 to 1.8 mya), compared to previous epochs, was a relatively brief period of only 3.5 million years. The name *Pliocene* means "more recent." During this time, the earth approached its current form, with ice caps, relatively modern geography, modern mammals, and the evolution of hominids. Continents had taken up their present positions. Both North and South America were drifting northward. However, South America was moving somewhat faster, related to a shift in the Caribbean tectonic plate. Thus, a permanent land bridge between the Americas developed in the mid-Pliocene, allowing mammals to migrate across. The closing of the Isthmus of Panama isolated the waters of the Gulf of Mexico and separated the marine biota of the east and west coasts. This tectonic episode had major consequences for global temperatures, because warm equatorial ocean currents were cut off and the climate became cooler and drier. At the same time, the Himalayan uplift accelerated the unfolding cooling process.

The Pleistocene epoch (1.8 to .011 mya) is known as the ice age, because this short epoch witnessed a dramatic, continued cooling, culminating in a series of advances and retreats of the ice as the climate fluctuated between cold (glacial) and warm (interglacial) periods at periodicities fitting Earth's orbit cycles (Milankovitch cycles). The sea level rose during the melting of the glaciers; then land bridges, created during cooler periods when glaciers sequestered more water, enabled the migration of animals and humans across continents. The term *Pleistocene* ("most recent") was coined for strata with 90% to 100% present day species. Animals and plants were basically modern species, although distributions were unusual. The great mammalian megafauna flourished. Many giant mammals evolved and lived on all continents. During the Pleistocene, the hominid tendency to increase brain size and hence intelligence continued, and finally modern man (*Homo sapiens*) emerged.

The Holocene epoch covers the last 11,500 years of the Neogene period. The term *Holocene* means "completely recent" and refers to the present geological epoch. The Holocene represents a marked climatic warming phase corresponding to the present interstadial (warm period between glaciations) phase. All other ages, epochs, and eras are represented by natural evolutionary and geological phenomena. The Holocene in contrast is distinguished by being the epoch during which there has been an exponential growth in human population and knowledge. Human activities have had a marked, and for the most part extremely detrimental, effect on the rest of the biosphere.

Nero, Emperor of Rome (37–68 CE)

Nero Claudius Caesar was the fifth of the five Julio-Claudian emperors and one of the most notorious. Two millennia after his death, his name continues to conjure images of a cruel, self-indulgent tyrant who "fiddled while Rome burned." He is also legendary for being one of the first rulers to order the persecution of a small religious sect known as the Christians. Despite the overwhelmingly negative views of Nero and his rule, he represents an important period in the history of Rome. Nero was the last emperor with a hereditary link to Julius Caesar. He reigned at the end of a century of peace. After his death, civil war broke out. Because Nero had ordered the death of any relative who might inherit the throne after him, when he died the throne was open to anyone with the power to claim and keep it.

Early Years

Nero was born in Antium in December, 37 CE, and was named Lucius Domitius Ahenobarbus. His father, Cnaeus Domitius Ahenobarbus, was a member of a distinguished noble family of the republic. His mother, Agrippina the younger, was the daughter of Germanicus. When Lucius was 2 years old, his father died. The reigning emperor, Gaius (Caligula), brother to Agrippina, seized his inheritance and banished mother and son to the Pontian Islands, where they lived in near poverty. Caligula and his wife and infant daughter were killed in 41 CE. His uncle Claudius, a far milder ruler, ascended to the throne and recalled his niece and her son from exile. Agrippina, a very ambitious woman, promptly arranged a proper education for her son.

In 48 CE, Claudius had his wife Messalina executed for adultery. The following year he married his niece Agrippina, and she furthered Lucius's prospects by having him betrothed to his stepsister Octavia (whom he married 4 years later). Lucius completed his education under the tutelage of the eminent Stoic philosopher Lucius Annaeus Seneca. In 50 CE, Agrippina persuaded Claudius to formally adopt her son, securing his place as heir to the throne. Lucius's name was officially changed to Nero Claudius Drusus Germanicus.

Emperor Nero

Claudius died in 54 CE—probably poisoned by his wife. Nero claimed the throne with the support of the praetorian prefect Sextus Afranius Burrus. Agrippina acted as regent to the 16-year-old emperor. Nero's first few years as ruler were stable, led by the sound guidance of Burrus and Seneca. Nero announced that he would model his rule after that of Augustus, a very prestigious and respected ancestor. Nero applied himself to his judicial duties, granting more freedom to the senate, forbidding the killing of gladiators and criminals, lessening taxes and the extortion of money by provincial governors, and making reforms to legislation.

Difficult decisions and administrative pressures eventually caused Nero to withdraw. He devoted himself to pleasures: chariot racing, singing, poetry, acting, dancing, and sexual activity. Seneca and Burrus attempted to keep his performances private and the government running smoothly. Agrippina was furious about (some say jealous of) Nero's conquests. She also deplored her son's interest in Greek art. Nero grew hostile toward his mother as news of her virulent gossip came back to him.

Nero's life reached a turning point when he took a new mistress named Poppaea Sabina. Agrippina supported his wife Octavia, who was naturally opposed to this latest affair. Nero responded by making various attempts on his mother's life. After three unsuccessful attempts to poison her, the ceiling over her bed was rigged to collapse while she slept. That also failed, so a boat was constructed that would break apart and sink in the Bay of Naples. However, Agrippina managed to swim ashore as the boat sank. An exasperated Nero finally sent an assassin who clubbed and stabbed her to death in 59 CE. Nero reported to the senate that his mother was plotting his death and he had no choice but to retaliate. The senators had never approved of Agrippina and did not question her removal.

Nero celebrated his freedom with even more contests, festivals, and orgies. He sang, acted, and played instruments in public. Performers were considered unsavory, so it was an outrage to have an emperor on stage. In 62 CE, Burrus died from an illness. He was succeeded as praetorian prefect by two senators who were corrupt and encouraged Nero in his excesses. Seneca found the situation uncontrollable and resigned. Nero's life became a series of scandals. He divorced Octavia and had her killed later that year. He then married Poppaea, who was also killed by Nero a short time later.

Despite Nero's behavior in Rome, the empire as a whole was relatively peaceful and prosperous until one of the greatest disasters in Rome's long history occurred. In July of 64 CE, the great fire of Rome ravaged the city for 6 days. When it was finally contained, 10 of the 14 districts of the city had been reduced to rubble and ashes. After the fire, Nero claimed a vast area and began construction of his "Golden Palace." Given the vast size of this complex, it could never have been built before the fire. The Roman people began to have suspicions about the source of the blaze. Nero, always desperate to be popular, looked for a scapegoat to blame. He found a new, obscure religious sect called the Christians. Many were arrested, thrown to the wild animals in the circus, burned to death, or crucified.

Beginning of the End

A large-scale conspiracy planned by a number of senators to remove Nero from the throne was discovered in 65 CE. The 27-year-old had been emperor for more than a decade, and the only positive result of his reign was the strict building codes put into place after the great fire, making Rome a safer and more attractive city. Nero's response to the conspiracy was to take an extended tour of Greece while his prefect decimated the senatorial ranks by execution or ordered suicide. In the year 68 CE, another revolt began in the provinces. Galba, an elderly provincial governor, claimed the throne and marched his troops toward Rome. Nero was abandoned by the few supporters he had remaining. The senate ordered Nero's death. Nero heard and chose to commit suicide instead, with the assistance of his secretary. He died on June 9 in the year 68 AD. Even at the very end of his life, Nero remained more concerned with his artistic pursuits than affairs of state. His last words were "*Qualis artifex pereo!*" or, "What an artist the world loses in me!"

Nero ruled when there had been over 100 years of relative peace. Despite his antics in Rome, the people in the rest of the empire lived well enough to prevent unrest. Before Nero's death, he had every relative who might ascend to the throne killed, to assure that a child with his blood would rise to power. After he died childless, civil war broke out, because the throne was open to anyone who claimed it. The last of the Caesars was succeeded by a series of provincial strongmen with personal armies.

NEVSKY, SAINT ALEXANDER (1220–1263)

During his short life, Saint Alexander Nevsky, born Aleksandr Yaroslavovich, made his mark in history as one of Russia's best-known Christian military commanders; he protected Russia against European invasion during the Middle Ages. He was heralded as savior of the Russian Orthodox Church.

A military strategist of the time, Nevsky's triumphant defense against the invasion of Russia by the Swedes, the Teutonic Knights, and the Lithuanians saved Russian culture. Many historians believe that, through his collaboration with the Mongols, Nevsky was able to save Russian lives and land and also saved Russia from Roman Catholic control, thus preserving the Orthodox faith. He also did much to advance the centralization of the Russian government.

Nevsky's role as defender of Russian land from the German and Swedish feudal lords began when he was at the tender age of 16, when he became the duty-bound prince of Novgorod. His legendary victory over the Swedes, who in 1240 attempted to block Russia's access to the Baltic at the Battle of Neva, earned him both the name of Nevsky and a place in history by raising him to legendary status. The military tactic of a surprise lightning attack in this battle ensured Nevsky's victory. This was an especially significant event because it prevented an all-out invasion of Russia by the Swedes. This victory further strengthened the young prince's political aspirations.

When the invasion of Russia was again at hand, Alexander Nevsky again went to war. His victorious battle with the German Knights in the Battle of the Ice in 1242 was a significant historical event of the Middle Ages, for it was in this victory that foot soldiers first defeated mounted knights, a military tactic that was to become a timeless battle strategy. This victory and the victory over the Lithuanians in 1245 established Nevsky as a one of the greatest military leaders of that time and ensured the survival of Russia.

In 1246, Nevsky faced a problem that would require his skills not on the battlefields but in diplomacy. The problem concerned a loss of Russian independence. At this time, with the Mongols' conquest of eastern Russia, Nevsky wisely cooperated with them. He was made Grand Prince of Vladimir (1252–1263), and his cooperation with the Mongols allowed him to protect the Orthodox Church from aggression, to spare Russians from further hardship, and to achieve some stability in northern Russia.

Nevsky died in 1263. The end of his leadership was a loss deeply felt by the country, but his heirs ruled Russia until 1917. With his successors and descendants, princes came to be monarchs in Moscow. In death, he continued to be an influence in Russian history. In the 14th century (1381), Nevksy was elevated to the status of a local saint, and in 1547 he was canonized by the Russian Orthodox Church, because his collaboration and intercession with the Mongols helped to maintain Russia's way of life and religious freedom and prevented much bloodshed. This endeared him to the Russian people.

The Alexander Nevsky Monastery, founded in 1710, now includes some of the oldest buildings in the city of St. Petersburg and burial places for some of the giants of Russian culture. In 1725, one of the highest Russian military decorations, the Order of Alexander Nevsky, was established to revive the memory of Alexander's struggle with the Germans, and in 1836 a triumphal arch was erected in his memory and a principal street was named for him in St. Petersburg. In 1937, Sergei Eisenstein made a classic film to promote Russian nationalism using Nevsky as the subject. The Soviet Order of Alexander Nevsky was introduced during the Great Patriotic War of 1942.

Several Russian naval vessels were named for him, including the 19th-century frigate *Alexander Neuski*. Without Nevsky's leadership the history of Eastern Europe and thus of the world might have been very different.

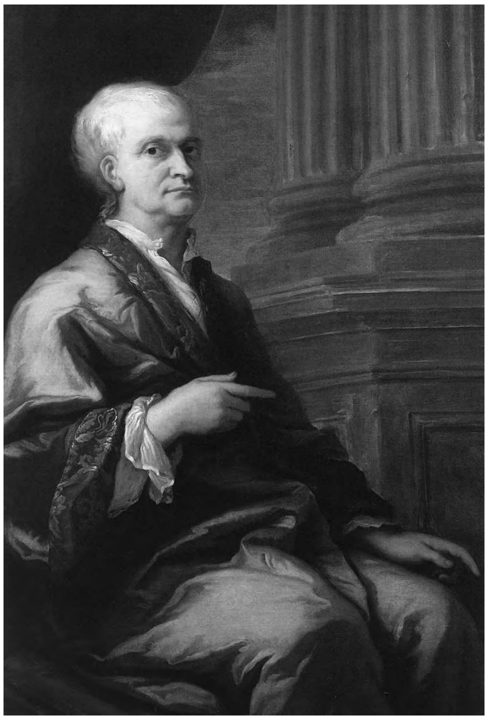
NEWTON, ISAAC (1642–1727)

Sir Isaac Newton, English natural philosopher, mathematician, and physical scientist, revolutionized the theoretical concepts regarding the physical laws that govern the universe. The impact of his contributions to the understanding of the mathematical perspective of motion, space, and time provided the means to further challenge both the Aristotelian foundations of science and ecclesiastical authority over science. Additionally, Newton's metaphysical distinctions based on his theoretical principles drew criticism from many theologians and philosophers of the Enlightenment traditions, including rationalist and empiricist.

Praised as a scientist and ridiculed as a philosopher, Newton attempted to construct a metaphysical bridge in order to reconcile the mechanics of the universe with God, but his attempt was vastly underscored or dismissed. For Newton, there had been a conflict between traditional or orthodox religion and science that he now attempted to overcome in presenting his own unorthodox metaphysical approach to God and God's significance for the universe and humankind. Newton's major works include *Philosophiae Naturalis Principia Mathematica* (1687), *Opticks* (1704), and *Arithmetica Universalis* (1707).



Portrait of Sir Isaac Newton (1642–1727) by Sir James Thornhill. A mathematician, physicist, and English astronomer, Newton proposed that gravity was a universal force and that the sun's gravity was what held planets in their orbits.

Newton's scientific, albeit philosophical, explorations in the laws that govern the physical universe are steeped in cursory observations, rational speculations, and mathematical computations. Regarding the temporal nature of the universe and its relation to physical matter, the abstract notions of motion and space are irrevocably united within the conceptual framework of a theoretical and sometimes theological framework. Beyond the eternal, infinite, and geocentric concepts set forth by Aristotle (384–322 BCE), Ptolemy (c. 90–168 CE), and, theologically, Saint Thomas Aquinas (1225–1274 CE), the scientific advancements of Nicolaus Copernicus (1473–1543), Galileo Galilei (1564–1642), and Johannes Kepler (1571–1630) changed and influenced previous perceptions of space, motion, and more important, time. Newton influenced and integrated advancements in both science and philosophy within his perspective; he furthered scientific advancements by creating a mathematically systematic approach to explain the natural phenomena of the universe. These secular contributions to science and mathematics, along with a theistic cosmological perspective, had secured the separation of physics from theology. Interesting and yet obscure, the theistic tendencies within Newton's cosmology possess a confounding blend of ontology and teleology.

Newton provided a scientific explanation for the symbiotic relationship of gravitation and motion. In the explanation of the physical phenomena observed on this planet and in the universe, he calculated that gravitation had an effect on physical bodies, from earthly objects to celestial bodies. In resolving the terms of motion, Newton had stated three laws:

1. Motion is constant until an external force is applied.
2. Force can be calculated by the relationship between mass (m) and acceleration (a); thus $F = ma$.
3. Every action has an equal and opposite reaction.

These explanations in terms of motion have unique implications for the concept of time. Time and space, interrelated and reflected in Newton's established laws, are not in constant and fluid motion. Objects exist in absolute time, and absolute space is perceived in relation to motion. This would question the exact nature of space—space being a void or some reactionary force—and the conceptualization of time in terms of the interactions between the mass and velocity of bodies. Furthermore, a lack of knowledge regarding physical composition, especially of celestial bodies, and its relationship to space and motion, would have greater implications. Although Newton provided mathematical computations to support his rational speculations, his metaphysical implications drew criticisms from both philosophers and scientists with differing theological and philosophical perspectives. However, as a precursor to the work of Albert Einstein (1879–1955), these speculations would lead to monumental contributions to theoretical physics.

The concept of time and its relationship to our own species' developmental ontology and teleology are easily tracked within the historical accounting of philosophical ideals. Reflected in these ideals, self-awareness and temporal perception are uniform; some are supported in part by mathematics. Time becomes an integral part of human existence far beyond the physical mechanics of the universe. For Newton, this reality in the concept of time is often underscored. Within his theistic cosmology, Newton acknowledged that a divine power existed that was both infinite and eternal. Space, similar to this divine power, was infinite yet containing finite objects. These celestial bodies, placed within the confines of space, are not only maintained by a divine force but also explained in terms of mechanical operations of gravity within space. The necessity for a stable system, both theologically and cosmologically, became paramount. The infinity of the universe, as opposed to sidereal boundaries of space, precludes any philosophical distinction and definition of what exists beyond the boundaries of time and space. The distribution of stars and planets, albeit complete solar systems, are finite within the infinite. For Newton, the temporal nature of the material universe, involving creations, recreations, and dynamic (yet stable) changes, was beyond the depiction of time necessitated by religious scripture. The age of the solar system was steeped within the immensity of time. Regardless of the duration of time, the material universe and the mechanical operations of gravity and motion remained to be the sole factor in Newton's argumentt for the existence of God.

The cosmological ideas of Newton concerning the sensorium of God, though heretical, depicted an infinite universe governed by the mechanical operations of an intelligent and divine power. Contrary to the views of his day, the previous Aristotelian order and operation of the universe was replaced by a mathematically ordered universe that reflected this divine power. Motion was considered not as a result of the actions of an unmoved mover but of natural laws of gravity, acceleration (velocity), and space. Although Newton never attributed this design to the Greek notion of *logos,* the natural order and laws that govern the solar system and stars was reduced to a theistic "proof" of God's existence, although Newton's perspective on the basic structures of Christianity remains elusive.

Regardless of Newton's theistic beliefs, the universe, stars, solar systems (perhaps multiple systems), and planets were much older than depicted in the Bible. With the errors within scripture being pervasive, it would be interesting to speculate on Newton's own temporal view of our species. The concept of time, regardless of scientific advancements, becomes a personal and universal reality by means of which human beings are aware. Motion and its related mechanical principles illuminate this concept of time and our relation to the external world. Newton's contributions to understanding of gravity, motion, and abstract notions of time and space (finite and infinite) were critical for the foundations for modern physics.

Newton and Leibniz

The controversy between Isaac Newton (1642–1727) and Gottfried Wilhelm von Leibniz (1646–1716) was primarily over their views of space and time. There had been some claims among Newton's followers that Leibniz had plagiarized from Newton, particularly regarding the calculus. It was later proved that there was no plagiarism, but that these two geniuses, standing on the shoulders of those (like Johannes Kepler, for example) who had preceded them, had each made the conceptual leap independently to the calculus. However, Newton (somewhat paranoid) may have retained some feelings of resentment toward Leibniz, and thus does not respond to him directly about their differing views; rather, the differences are aired primarily in the correspondence between Leibniz and Samuel Clarke, a follower of Newton.

Newton had expressed his views on space and time in his *Principia Mathematica* (1686), in the scholium following the section on definitions. He explains why he did not include in the definitions time, space, place, and motion, because they were well known to everyone. However, people commonly held prejudices regarding these concepts, so he expounds his technical definitions. "Absolute, true, and mathematical time, of itself, and from its own nature, flows equably without relation to anything external." It is also called duration. Relative, or common, time is a sensible measure of duration (by means of motion). "Absolute space, in its own nature, without relation to anything external, remains always similar and immovable." Relative space is somehow a measure of this absolute space. It is important to look at both concepts together, because they share characteristics that may help in understanding what Newton means. Space (absolute space) is a kind of permanent container in which things may come and go, appear and disappear. Imagine a huge matrix on which one might move pieces (a kind of cosmological chess board); the pieces may move and change, but the board always remains. By analogy, absolute time is always flowing, and does not depend for its existence on the motion or change of bodies. Change implies a before and an after in time, which therefore presupposes time, so it must be more fundamental, an objective reality, according to Newton. He says that absolute time would exist even if there were no motion, or a lapse between motions.

Leibniz denies that space and time are absolute; he argues that they are relative, that they are relations. Space is the order of perceptions of monads (a monad is Leibniz's basic metaphysical, indivisible substance, a concentration of energy, a kind of mind) that coexist; time is the ordering of a monad's different perceptions. Because space and time depend on monadic perceptions (of the world), they are ideal (phenomenal), not real. Just as other relations (such as "smarter than") do not have an independent existence, but are dependent on the entities compared, neither do space and time have an independent existence. Time is more fundamental; for a monad, the present is represented clearly, the past and the future more obscurely. Space is then the ordering of coexisting monads (or aggregates of monads) at the same time. Leibniz argues that there is a continuum of monads in this best of all possible worlds. (God would have created nothing less; existence is maximized in the best possible world.) If there had not been a best possible world, God would not have had a sufficient reason to create anything.

A controversy between Leibniz and the Newtonians began in 1705 over these serious disagreements. It culminated in 1715–1716 with an exchange of letters between Leibniz and Samuel Clarke, a follower of Newton. It began with a criticism of Newton's position sent by Leibniz to Princess Caroline of Wales; Clarke responded on behalf of Newton, Leibniz wrote back in defense, and so on. There were five letters written by Leibniz, five replies by Clarke, and it ended without resolution, at the death of Leibniz.

Leibniz begins his first letter by attacking Newton's materialism (of atoms and void) and its implications for religion. He argues that Newton's system implies that God is a kind of unskillful watchmaker who has to fix and adjust his creation periodically and has need of space as his sense organ. Clarke responds that God needs no medium of perception, because he is omnipresent. Clarke argues that a God who does not attend to his creation would be like a king who ignores his kingdom and lets it run on its own. Leibniz responds that God, in his wisdom, foresaw everything and has made the best possible world machine, which consequently does not need his intervention; his action, as supreme ruler, is that of continually preserving his creation.

Leibniz's fundamental principle is that of sufficient reason (nothing happens without a sufficient reason why it is so and not otherwise), a rational self-evident truth. If space were a real absolute being, as Newton says, all points in space would be indistinguishable, and there would not be a sufficient reason why God placed bodies in one arrangement rather than its opposite (east instead of west, for example). Similarly with absolute time, its parts would be uniform, so there would not have been a sufficient reason why God created everything *when* he did, and not sooner or later. Clarke replies that God's will is the sufficient reason for creating how and when he did. He attacks the idea of space as relational by saying that if God reversed the position of the stars with that of the moon and Earth, on a relational account, it would be the same, which is contradictory. Or if God moved the material world in a straight line at any speed, on the relational account it would continue in the same place and time (which is absurd).

Leibniz calls Clarke's examples impossible fictions, and says that Clarke did not understand the nature of relational space, by supposing that a world would be moved against an absolute background space and time, which is what is denied. Two indiscernible states are the same state, says Leibniz, and so "'tis a change without a change." Another fiction is that God might have created the world sooner, because God does nothing without a sufficient reason. Leibniz says that the order of bodies (aggregates of monads) makes space/situation possible, just as the succession of bodily states makes time/duration possible. If there were no creatures, there would be no space and time. Clarke reiterates that there can be identical parts of space that are yet distinct, and two points in time that are identical; quantity of time can be greater or less, yet the order of temporal events could be the same. Leibniz's principle of continuity denies this; between any two states there must be another state, so greater elapsed time implies more successive, distinct states.

Clarke argues that Leibniz's universe destroys freedom; everything would be determined. Leibniz replies that he has argued at length, in his *Theodicy,* that God's foreknowledge is compatible with free choice. God, in his wisdom, simply created (thought) the one possible world full of free creatures that was the best "actualizing their free natures." What God did not create, in thinking the best world, is nevertheless possible.

Leibniz argues that absolute space and time would be infinite and eternal and so independent of God, thus possibly greater than God (which is contradictory). If being *in* space and time is necessary to God, he would then be in need of them and thus limited (but God is without limits). Motion depends on a change that can be observed. Time without things, Leibniz says, is only an ideal possibility; to say the created world might have been created sooner is not intelligible (if it *could have* been created sooner, God would have done so, because that would mean more existence). Space and matter are different, but inseparable; time and motion are distinct, but inseparable, says Leibniz.

Nicholas of Cusa (Cusanus) (1401–1464)

Nicholas of Cusa (Kues), a German cardinal of the Roman Catholic Church, philosopher, jurist, mathematician, and astronomer, is widely considered as one of the greatest geniuses of the 15th century. He received a doctorate in canon law from the University of Padua in 1423. His ideas influenced philosophical, political, and scientific thought and anticipated the work of astronomers Nicolaus Copernicus and Johannes Kepler.

Generally speaking, Cusa's theory of time exemplifies a Christian Platonism whose elements already had a long tradition (in, e.g., the work of Saint Augustine of Hippo, William of Conches, Albert the Great, and Saint Thomas Aquinas). Cusa's elaborations of this material, however, are sometimes quite original. Space permits inclusion here of only a few examples from among his many discussions of the topic.

In *De venatione sapientiae* (1463), Cusa begins his exposition of the subject by dealing with eternity, the image of which is time (*imago aeternitatis*). Eternity itself (*aeternum*) has to be distinguished from "perpetuity" (*aevum et perpetuum*): Whereas eternity is a mode of duration that has absolutely no beginning and no end, such that it is the peculiar mode of being of God who can himself be called eternity (*aeternitas*), perpetuity designates a duration that has no beginning and no end within the realm of time. On the other hand, the subjects of perpetuity, like the heavenly entities (*caelestia*) and the objects of pure thought (*intelligibilia*), transcend the realm of coming-to-be and perishing. Those passages, where Cusa distinguishes two senses of eternity—the pure eternity of God and the derivative eternity of the perpetual elements of the cosmos—have to be understood according to the same passages; that is, they also reflect the distinction between eternity and perpetuity. Cusa describes eternity as the realm of things that have a being as possible things (*posse fieri*). The existence of such *possibilia* is a necessary condition for God's being able to create the sensible world. The eternal objects themselves, however, are not created, but initiated (*initiata*). In this respect, Cusa echoes the Scotistic model of eternal ideas within God, which are the elements of the world in possibility while they are necessary in their own form of existence as *possibilia*. Time, on the other hand, has the connotation of change, of coming-to-be and perishing—in other words, of the sensible world. Only in this respect, Cusa sometimes also uses the Aristotelian definition of time as a measure of motion. The creation of the sensible, or timely, world is described in Neoplatonic terms as the unfolding (*explicatio*) of that which exists not unfolded (*complicite*) in the intelligible realm of perpetuity. The intelligible world is already structured in a way that enables God to create our world in its beauty. It is probably because of this connection of both the intelligible and the sensible world that Cusa sometimes calls the world itself eternal (*aeternus*) without qualification: the world in its entirety, that is, including the intelligible world, has no beginning in time; rather, it is the realm within which time begins and ends. In the eternity of God himself, on the other hand, the difference between the two worlds of being able to coming-to-be (*posse fieri*) and existing actually (*esse actu*) is suspended, because he alone is what he can be (*possest*). It is obvious from these remarks that Cusa's theology stays fairly close to the classical Neoplatonic system from late antiquity, though he reformulates it in terms that show some traces of the earlier Christian discussions. In ancient Neoplatonism, however, these ideas about time and eternity were closely connected with the idea of an eternal cosmos, which contained only a limited number of souls that migrated from one body to another one. Thus, it is no surprise that Cusa has difficulties explaining in which way the eschatological elements of Christian thought—that is, the resurrection of the dead—can be explained as related to time. In his early work *De docta ignorantia,* he explains that at the time of resurrection we will arrive, because of the end of all motion, at a place beyond time (*supra tempus*). But this process of transcending that way of being into which we have been born cannot be explained by philosophical reasoning, and consequently Cusa in his subsequent works does not give a new treatment to this question.

In his sermon *De aequalitate* (1459), Cusa approached the problem of time from another point of view. Here, he discusses the relation between soul and world in a way that is clearly inspired by Augustine's treatment of the topic in *Confessiones XI:* The soul sees that it is "timeless time" (*anima videt se esse intemporale tempus*). This is because it apprehends time to exist only in the world of change. While the soul sees itself as an active element of this world, and consequently as an element of time, it understands too that it is in its essence separate from all temporality, because it can find in itself both the past and the future moments of time, which do not exist in the world of change. Insofar as all three stages of time are present to the soul, each of them can be called "perfect time" (*tempus perfectum*). According to Cusa, the past is the memory (*memoria*) of the soul, the present its intellect, and the future its will. All of them depend, insofar as they are in the soul, on memory as their reason of being (*quia est*), but what they are (*quid est*), they are as objects of the intellect; in the will they are like an intended goal (*in intento fine*). Though the soul can liberate through these activities the instants of time from its necessary connection with elements of the world, its own existence is still timely, because the soul itself is directed toward the moments of the successive time. In this regard, it recognizes itself as different from eternity: It is in a timely way free from corruption, but not absolutely free from it as God is. It is an analogy to eternity (*similitudo aeternitatis*), but not itself eternity.

In principle, the more perfect intelligences (which must probably be understood as the angels, but the concept clearly echoes the Neoplatonic doctrine of *nous*) are in the same situation of existing timeless in time. But while they always have an active awareness of their natural state, the human soul has to strive for such an awareness by reducing its dependence upon the timely world. The relation between time and the human soul is treated again in the second book of *De ludo globi* (1463). In this work, the timelessness of the soul is explained by its intention to reach its highest good, the science of God. In its fundamental "first intention," the soul is free of any change, but one can speak about change insofar as the soul's "second intentions"; the soul's actual strivings are subject to many changes that, however, do not infect its timeless and changeless essence. This solution reminds the reader of the theories of Albert the Great (who is the interlocutor of the cardinal at this place) and of Aquinas's theories of a natural striving for the good that cannot be lost. From Cusa's explanation of *De aequalitate,* the new account differs insofar as it presupposes a difference between timely change and substantial timelessness in the soul itself.

Nietzsche, Friedrich (1844–1900)

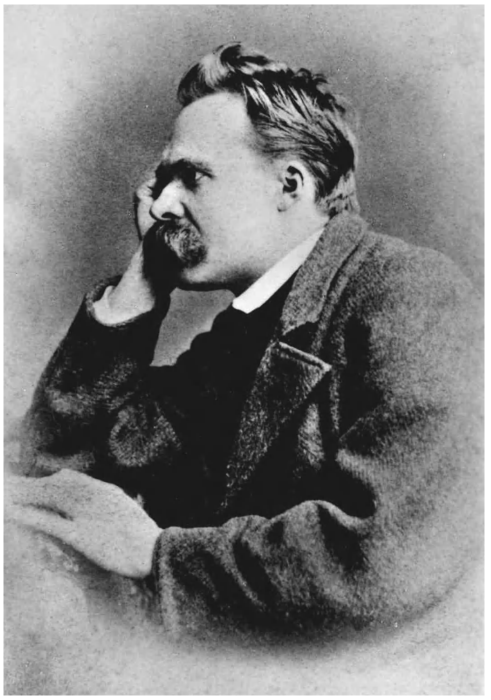
Friedrich Nietzsche has emerged as perhaps the most influential thinker of the recent past. To a significant degree, this is due to the fact that he took time seriously in terms of both cosmology and ethics. Nietzsche offered a dynamic worldview that rejected the entrenched Aristotelian philosophy and Thomistic theology of Western civilization. His provocative writings contained scathing criticisms of modern European culture, particularly its religious beliefs and social morals (all decadent values, as he saw them).

Nietzsche spent his formative years in Röcken and Naumburg, Germany, where he developed a lasting interest in music and literature. At universities, his academic concerns shifted from classical philology to ancient philosophy. He became fascinated with the early culture of Greece, especially the fundamental idea of Heraclitus, which maintained the cyclical flux of all reality. Furthermore, Nietzsche stressed the necessary value of feelings and emotions (over the use of reason) for human creativity and fulfillment. His own emerging ideas were greatly influenced by the seminal writings of the philosophers Ludwig Feuerbach and Arthur Schopenhauer.

After his studies at Bonn and Leipzig, Nietzsche became a professor at the University of Basel, Switzerland. Due to chronic illnesses, he left the university after 10 years and became a solitary wanderer in the mountains of southern Europe. The following years gave the philosopher free time to rigorously reflect on the place of our species within both Earth history and sociocultural development. He wrote a series of ingenious books, his masterpiece being the four-part poetic work *Thus Spake Zarathustra* (1883–1885).

Over time, Nietzsche wrote blistering criticisms of Christianity that dismissed all the basic beliefs of traditional theism. He boldly proclaimed that "God is dead!"—guaranteeing himself a permanent place in Western thought. He remained an unabashed atheist his entire life.

It was Charles Darwin the scientist who awoke Friedrich Nietzsche the philosopher from his dogmatic slumber. Although he benefited from reading Darwin's writings on evolution, Nietzsche's own interpretation of organic evolution offered startling philosophical speculations that were far beyond the views of his scientific naturalist contemporaries. The Darwinian struggle for survival (existence) became the Nietzschean struggle for power (creativity). The iconoclastic Nietzsche also called for a rigorous reevaluation of all values, because he saw religion, democracy, communism, and utilitarianism promoting values that were reducing human beings to a collective mediocrity. Consequently, he stressed the value of those superior individuals who are unencumbered by the vacuous ideas and false beliefs of the inferior masses.



One of Nietzsche's most important ideas, that of eternal return, is the theory that there is infinite time and a finite number of events, and eventually all events will recur again and again.

For Nietzsche, dynamic reality is essentially the will to power. As such, all the objects of this evolving universe are composed of vital energy as units of force. This is a strictly naturalistic stance that gives no credence to philosophical idealism or theological spiritualism. Throughout time, this will to power continuously creates all those objects that fill this evolving universe. If a steadfast observer with a high-powered telescope had witnessed, over billions of years, organic evolution on Earth from the surface of our moon (the process rapidly accelerated like a time-lapse film), then he or she would have experienced life forms exploding into an astonishing diversity of plant and animal species: One-celled organisms are followed by multicellular life forms, invertebrates precede vertebrates, and fossil apes give rise to human beings. Briefly, the creating universe includes creative evolution.

In terms of organic evolution, Nietzsche held that the human animal is a temporary link between the fossil apes of the remote past and the overbeings who will emerge from our species in the distant future. Moreover, in the creative sweep of biological history, he claimed that the overbeing to come will be as advanced beyond our species as the human animal of today is advanced beyond the worm! Quintessentially, this incredible progress will be made in terms of intellectual development (rather than merely temporal changes in physical characteristics). As a result, Nietzsche concluded that the overbeings to come are the meaning, purpose, aim, and goal of organic evolution on earth. These forthcoming noble beings will devote their superior intellect to creating artistic works and new values.

In early August 1881, while walking along the lake of Silvaplana near Sils-Maria in Switzerland ("6000 feet beyond man and time"), Nietzsche came upon a huge pyramid-shaped boulder. In a flash of intuition, he grasped a provocative perspective. This incident caused him to reflect upon time and, consequently, to develop his colossal idea of the eternal recurrence of this same universe. The resultant awesome temporal perspective that now occurred to him justified (so he thought) his philosophy of overcoming; the struggle for existence is worthwhile if one's personal life somehow continues to exist throughout time in this material reality. Nietzsche was delirious with joy over his immortality-granting idea. He even contemplated studying the natural sciences in order to empirically demonstrate the scientific truth of eternal recurrence.

Nietzsche argued that cosmic time is eternal, while cosmic space is finite. Moreover, he held that there is only a finite amount of matter and energy in this universe. Therefore, only a finite sequence of objects and events may take place in a cosmic cycle. But if time is eternal, then this finite cosmic cycle will repeat itself again and again. In fact, Nietzsche argued that this identical cosmic cycle has repeated itself an infinite number of times in the past, and it will repeat itself an infinite number of times in the future. Thus, material reality is the eternal recurrence of this identical universe, with no progressive evolution from cycle to cycle.

If true, then the ramifications of this cosmology are staggering for human existence. In general, it meant that everything that has ever existed will appear again in the same finite sequence throughout eternal time. In particular, it means that Nietzsche will never pass out of existence forever, since he will eternally return as the same individual living the exact life in every detail in each finite cycle. It also embraced the evolution of morality from the premorality of fossil apes to the metamorality of the future overbeings yet to emerge. In short, for our species today, eternal recurrence challenges one to seriously consider both the choices one makes and the values one holds.

Nietzsche's pervasive "Yes!" to dynamic reality, and therefore to cosmic time, is an affirmation of life with far-reaching implications for ethics, morals, and values beyond good and evil. It commands that every choice a person makes is a decision for eternity. In short, once is forever! Because an individual has no knowledge of his or her previous life, it is as if one is free to make choices, but this freedom is, in fact, an illusion. Moreover, each moment of existence has eternal value in this universal wheel of time.

Friedrich Nietzsche claimed that he wrote in blood and philosophized with a hammer. His this-worldly stance repudiated the human, all too human ideas and moralities of common life. In his dynamic viewpoint, neither species nor values are fixed in nature. Nietzsche offered an astounding interpretation of time and human existence. His optimistic philosophy is ultimately grounded in a cosmic perspective that teaches the eternal recurrence of this same universe. He held that time is an endless series of finite cycles, with each cycle being absolutely identical to all the other cycles. His extraordinary vision of cosmic time remains both a challenging and an essential frame of reference for scientists, philosophers, and theologians.

NIETZSCHE AND HERACLITUS

The philosopher Friedrich Nietzsche (1844–1900), although extremely critical of many thinkers, completely accepts Heraclitus's concept of time and develops it further. When Nietzsche read Heraclitus he felt at home, because concerning the form and content of being, Heraclitus's philosophy is similar to that of Nietzsche. Concerning the content of being, both defend a natural philosophy of permanent change that leads to a never-ending process of overcoming and of creation and destruction of forms. Nietzsche specifies the content of being further by developing the metaphysics of the will-to-power. (*Metaphysics* here is understood as a description of the nature of the world, which in Nietzsche's case is monistic and this-worldly.)

Both thinkers agree, however, not only concerning the content of being but also concerning its form, which is cyclical. In Nietzsche's case this form is referred to as the *eternal recurrence,* whereas Heraclitus calls it the *great year,* which is supposed to have a (metaphorical) duration of 10,800 years. Nietzsche stresses the similarity of his concepts to Heraclitus's in various published and unpublished writings. In *Ecce Homo* he stresses that traces of his concept of the eternal recurrence can be found in Heraclitus, and in *Thus Spake Zarathustra* he himself employs the notion of the great year in order to explain his understanding of the form of being.

Eternal Recurrence, Time, and Salvation

Many Nietzsche scholars today (such as Volker Gerhardt) stress the ethical relevance of Nietzsche's concept of the eternal recurrence. However, the fact that he clearly compares his concept to Heraclitus's metaphysical one in his published writings shows that it was meant as a metaphysical one. This reading of the eternal recurrence gets further support from his plans to study physics in Paris for 10 years in order to prove his concept scientifically, as his friend Lou Andreas-Salome pointed out, and from passages in his notebooks that he did not publish himself in which he puts together arguments with which he tries to prove the eternal recurrence philosophically. All of these arguments fail or are insufficient. At the least they do not establish what they are meant to establish. From the premises he mentions, he cannot infer the eternal recurrence by necessity. This, however, does not mean that his arguments cannot be improved so that the premises actually imply the eternal recurrence of everything. In addition, current scholars who stress the ethical relevance of the eternal recurrence are surely correct in doing so. The eternal recurrence is of immense ethical importance, as it is Nietzsche's theory of salvation, and it can give meaning to people who do not believe in a Christian afterlife but rather in a this-worldly concept of existence.

Eternal recurrence implies that whatever you have done and will do will recur identically. You lived the very same life before you were born, and you will lead it again in the very same manner. This implies that your life will not be over when you die but that you will return again and again, and you will meet the very same people you know now, and you will have to go through all the pains and pleasures you have experienced and will experience. You will not remember that you have lived the very same life before, but if you hold this concept, then you can feel comfort in realizing that you will experience all the wonderful events you have experienced again and again. These events are not over and done with. On the other hand, a life might have been so terrible that the concept of eternal recurrence can be unbearable.

What is important concerning salvation on the basis of this concept is that you experience one moment that you can affirm completely. Once you have had such a moment, then all other moments before and after this one are justified by means of this one moment, because all the other moments have been and are necessary in order for that moment to occur, according to Nietzsche. By saying yes to one moment, you also affirm all the pain and suffering you have to go through to reach it. However, if you experience a moment that you can affirm completely, you are saved on the basis of this concept. Therefore, the eternal recurrence or the great year increases the importance of any single moment immensely. Scholars who focus mainly on the ethical aspect of this concept stress that it is like an existential imperative: One ought to live as if one's life were to recur forever without this actually having to be the case. This does not correspond to Nietzsche's way of thinking. He was a classical philologist who was trained to think metaphysically and ontologically and did so himself because he understood that if you wish to have the ethical side of the concept, it needs an ontological foundation. Hence, he considered proving it scientifically and attempted to argue for it philosophically.

Circular Time and Identity

Nietzsche's eternal recurrence and Heraclitus's great year, understood philosophically, have implications concerning ontology and the philosophy of time. Concerning ontology, the concept can be seen as the form of being, the circle in which all other worldly events occur. Concerning the philosophy of time, the concept implies the circularity of time. If we take the notion of the circularity of time seriously, then it does not imply that we have the *x* plus *n*th (whereby *n* has to be a natural number) circulation but only one. Hence, we cannot talk about infinite time but rather circular time, time that is in itself circular. According to this concept, everything that occurs, occurs infinitely often. However, it would be more appropriate not to say that anything occurs infinitely often but rather that the very same thing occurs again and again. In the end, it is not the same but rather the identical that happens again. The circularity of time therefore implies that there is the relation of identity in its strongest Leibnizian sense between the various circulations of the world. The qualities that are valid in one circulation are also valid for all others. Here we also have to include spatiotemporal qualities.

Nietzsche tried to prove this concept philosophically. He argued, for example, thus: The law of the conservation of energy demands eternal recurrence. However, this is clearly false. The law of the conservation of energy alone does not necessarily imply this concept. If we assume the conservation of energy but also that the amount of energy is infinite, then we have an infinite number of possible combinations. However, an infinite number of possible combinations excludes the possibility of the eternal recurrence. If we assume that energy is finite but space exists separately from energy and is infinite, then again we have an infinite amount of combinatory options. Even if it were the case that energy is finite and time and space were qualities of energy, the eternal recurrence does not follow by necessity, as it could be the case that the law that is responsible for the change of the energy is itself subject to change, which excludes the possibility of the occurrence of the eternal recurrence.

Even if we further assume that energy is finite, time and space are aspects of energy, and the law underlying the change is determined and unchanging, the eternal recurrence does not follow by necessity, as there is the option that energy can turn up in an infinite amount of sizes, which also precludes that eternal recurrence takes place. Only when we assume, in addition to the premises just mentioned, that energy can turn up only in a finite amount of sizes, eternal recurrence follows, as the law of the conservation of energy (which is already included in our premises) also entails the reversibility of all states of the world—another necessary premise. By adding the premises just listed, however, we significantly expanded the argument suggested by Nietzsche.

It has to be noted that the notions "energy" and "force" that Nietzsche employs can be substituted by the notion "substance." There is a fairly wide range of words that can be exchanged for one another. However, the meaning of the words depends on the context in which they appear. Hence, it is not usually the case that one word has only one meaning in Nietzsche's writing, which is why one must be extremely cautious when interpreting him. Nietzsche's worldview is based on one substance, to which he refers using a great variety of words. This one substance is not unified but consists of various will-to-power quanta, to which he also refers as "force" or "energy." When various will-to-power quanta are unified, will-to-power constellations come into existence. In his notebooks he tried to develop a will-to-power metaphysics. By doing so Nietzsche was the only thinker who further developed Leibniz's monadology. However, Nietzsche's was based upon only one, nonunified substance, as "will can only act upon will." Because one type of substance is all there is, time and space have to be aspects of it and cannot exist separately from it. In addition, this substance is finite, as Nietzsche tries to banish all aspects of infinity from his philosophy.

In practice, this undertaking has the following implications: An infinite force cannot exist; therefore the existing force has to be finite. Infinite divisibility cannot exist; therefore the divisibility of force has to be finite. As a further premise we thus get the following: Force is not divisible infinitely often but turns up only in certain quantities. The logic or law of change demands that it be based upon a certain, specific law, which Nietzsche described in detail in his will-to-power metaphysics. It is decisive for eternal recurrence that such a law exists and that it is unchanging. Furthermore, the reversibility of all states of the world at an instant has to be given. Nietzsche solves this problem by reference to the law of conservation of energy. All the reflections just mentioned were not made by either Nietzsche or Heraclitus. However, they correspond to Nietzsche's and Heraclitus's way of thinking. We can summarize the foregoing as follows:

1. There is only one substance.
2. Time and space are aspects of one substance but do not exist independent of it.
3. The complete amount of substance is finite.
4. The divisibility of the substance is also finite, that is, there is a minimal amount in which the substance exists that is not divisible any further, whereby the size is different from zero.
5. There is a certain law that is the basis for change of the one substance.
6. The reversibility of all states of the world at an instant has to be assumed.

Conclusion: In such a system, substance can have only a finite number of states.

Once all states are present, then, one state has to recur, as the possibility of recurrence is given. If one state of the world at an instant recurs, and if the law governing the change does not change either, all other states of the world have to recur in an identical manner. As infinity is excluded, we cannot talk about infinite time either. As time is an aspect of the one substance, it also has to be identical with the previous time. (The word "previous" here has to be understood solely as a metaphor.) Such an understanding of time can be applied only if time is circular and finite. On that basis, the objection that this cycle is different does not apply either, as it is not different. This objection goes as follows: This cycle is different from all the other cycles, for we are in this cycle and we are conscious of being within this cycle, which does not apply to the cycles *n* plus 1 or 2. Hence this cycle cannot be identified with the other cycles. However, individuals who argue in this manner do not take the notion of circularity seriously, because if they did, they would know that there is only this one cycle.
