This Encyclopedia is dedicated to Professor Berislav Žarnić who passed away on May 25, 2017. Berislav was an Associate Editor of the Encyclopedia and we deeply regret that he wasn't around to see the publication of the project to which he was greatly committed. We would like to acknowledge his important contribution.

Preface

The Encyclopedia of Educational Philosophy and Theory began its life in 1999 when Paolo Ghiraldelli and I decided to establish an encyclopedia dedicated to philosophy of education although a decidedly different kind of philosophy of education than what most English-speaking scholars have been conditioned to expect. Paolo came from Brazil with a double Ph.D. and experience in media. He was interested more widely in critical and cultural accounts. I came to philosophy of education from philosophy after working on Wittgenstein to a field dominated by analytic philosophy of education. I also brought to my vision of the field an interest in philosophy of science, existential philosophy, and critical theory. “Philosophy of education” is often taken to be an application of philosophy either looking back to the philosophical tradition of philosophers who wrote specifically on education like Plato, Rousseau, and Kant or the application of an analytic method to the clarification of education concepts. In my Ph.D. thesis on Wittgenstein, I came to the conclusion that while the analytic method (if against Wittgenstein admonitions we can talk of *one* method) provided rigor, logic, and argumentation, it did not recognize the cultural and social significance of language, as revealed by the early Wittgenstein who inspired a generation of thinkers on viewing education as a set of practices. Methodological rigor notwithstanding I decided that the Springer *Encyclopedia of Philosophy and Theory*, named after the journal of the same name, should embrace a much wider view of education in terms of both philosophy and theory. This construction to my mind helped to wider the terms of reference and aided the process of making “philosophy” and “theory” more socially and culturally inclusive. It helped also to recognize the fact that much theoretical work that has not raised an eyebrow in the field deserves attention of philosophers and educational theorists. Education as an academic subject is such a huge enterprise embracing many different specialities that it is given to a kind of fragmentation. This Encyclopedia while not attempting to provide a unified view at least is based on the intention of recognizing the theoretical and philosophical significance of many different branches. It is also explicitly based on two further principles: first, the Encyclopedia attempts to be socially inclusive and culturally responsive; second, while respectful of different traditions and specialities the Encyclopedia is forward looking as much as it is sensitive to the past. This means, for example, that we can include sections on Socrates and the Socratic tradition alongside Confucius and the

Confucian tradition. One of the motivating ideas is to update educational philosophy and theory in terms of the contemporary movements in policy, technology, teacher education, to name a few possibilities, and to see them in terms of the unfolding and development of globalization.

This philosophy of the Encyclopedia requires a full exposition in terms of the dynamic evolution and development of education as a discipline. It is a philosophy of openness and inclusion that admits for instance the significance of critical theory, postcolonialism, feminism, indigenous studies, gay studies, and disability studies. The same editorial openness is implicitly based on the principles of technology-enabled features of intertextuality and dynamic updating to make the Encyclopedia a living and working document. The intention is to include new sections and entries every year.

Finally, a word of thanks to Springer staff Nick Melchior, Alexa Singh, and Sunaina Dadlwal; to my Associate Editors Andrew Gibbons, Berislav Zarnic, and Tina Besley; and to all Section Editors and contributors. This reminds me how much of worthwhile scholarship and research is a *collective* process based on some form of peer review – a notion that while relatively recent is enhanced with the digital turn.

About the Editor

Michael A. Peters is Professor in the Wilf Malcolm Institute for Educational Research at Waikato University, New Zealand, Emeritus Professor at the University of Illinois at Urbana-Champaign, USA, and Professorial Fellow at James Cook University, Australia. He holds degrees in Geography, Philosophy, and Education from New Zealand universities. He trained as a secondary school teacher and taught for 7 years during the years 1971–1978 and taught at NZ universities before holding posts at Glasgow and Illinois. He has been a Visiting Scholar and Fellow at many universities around the world. He is the Executive Editor of *Educational Philosophy and Theory* and Founding Editor of several other journals, including the *Open Review of Educational Research* and *The Video Journal of Education and Pedagogy*. His research interests are broadly in areas of education, philosophy, social theory, and policy.

His recent writing and scholarly activity revolves around two main areas: contemporary philosophy focusing on critical theory and poststructuralism with a particular interest in philosophy of education, and the politics of education and social policy. The two areas of interest inform each other. In the first category, Peters develops a distinctive poststructuralist approach in philosophy and education.

He writes: “The deepest influences upon my thinking and writing include Wittgenstein, Nietzsche, Lyotard, Derrida and Foucault. These philosophers teach us how to think or philosophize in the postmodern condition in an age when the grand *récits* or metanarratives have lost their legitimating power. They also provide a positive philosophical response to nihilism, globalization

and to the fragmentation and dissolution of Western culture. For these thinkers also the question of the style of philosophy is paramount and it is productive to approach their philosophies as a kind of writing.”

He is currently editing *The Companion to Wittgenstein and Education: Pedagogical Investigations* (Springer) with Jeff Stickney. He coauthored *Saying and Doing: Wittgenstein as a Pedagogical Philosopher* (2008) with Nicholas Burbules and Paul Smeyers; and *Wittgenstein: Philosophy, Postmodernism, Pedagogy* (1999) with James D. Marshall. Other philosophical works include: *Education and the Postmodern Condition* (ed.) (1996); *Poststructuralism, Politics, and Education* (1996); *Derrida, Deconstruction and Education* (2004) and *Deconstructing Derrida: Tasks for the New Humanities* (2005) with Peter Trifonas; *Derrida, Politics and Pedagogy* (2009) with Gert Biesta; and *Subjectivity and Truth: Foucault, Education, and the Culture of the Self* (2008), *Why Foucault?* (eds.) (2007), and *Governmentality Studies in Education* (eds.) (2009), all with Tina Besley.

He is also interested in the philosophy and political economy of knowledge production and consumption within the academy having written many books on knowledge economy and the university. His current projects in this area include work on distributed knowledge, digital learning and publishing systems, and “open education.”

His written works in this area include most recently *The Global Financial Crisis and the Restructuring of Education* (2015) and *Paulo Freire: The Global Legacy* (2015), both with Tina Besley; *Education, Philosophy and Politics: Selected Works* (2011) and *Education, Cognitive Capitalism and Digital Labour* (2011), with Ergin Bulut; and *Neoliberalism and After? Education, Social Policy, and the Crisis of Capitalism* (2011), *Education in the Creative Economy* with Dan Araya (2010), and *Building Knowledge Cultures* (2008), with Tina Besley.

He is a lifelong Fellow of the New Zealand Academy of Humanities and he was made an Honorary Fellow of the Royal Society of NZ in 2010. He has acted as an advisor to government on these and related matters in Scotland, NZ, South Africa, and the EU. He was awarded honorary doctorates by State University of New York (SUNY) in 2012 and University of Aalborg in 2015.

About the Associate Editors

Andrew is an early childhood teacher educator and Associate Professor at the School of Education, Auckland University of Technology. He has worked in journalism, in the social services in England, and in early childhood education in Auckland. He is Executive Editor of *E-Learning and Digital Media*, Associate Editor of *Educational Philosophy and Theory*, and member of the Philosophy of Education Society of Australasia. He has published on a wide range of educational and philosophical topics including the role of technology in education, NZ ECE policy directions in the past two decades, the educational implications of the work of Albert Camus, the future of the university, the role of science fiction in education, and working conditions for early childhood teachers.

Berislav Žarnić is Full Professor of University of Split in philosophy, branch of logic. He works at the Faculty of Humanities and Social Sciences, University of Split doing scientific research and teaching logic, philosophy of

education, and philosophy of science at various departments. His main interests and scientific contributions belong to branches of philosophical logic and philosophy of education. In his current research, he applies the methods and results of contemporary logic in the analysis of educational communication, conceptual changes, and structure of educational theories. He has been coeditor of Internet Encyclopedia of Educational Philosophy and Theory (formerly, Encyclopedia of Philosophy of Education) since 2002. Personal web page: <http://marul.ffst.hr/~berislav>

Professor Besley returned to New Zealand in late 2011 after 11 years in universities in the United Kingdom and United States. From 2000 to 2006, she was Research Fellow and Lecturer at the University of Glasgow, Scotland.

She spent 6 years in the United States, which included 2 years as a full tenured Professor at the Department of Educational Psychology and Counseling (College of Education, California State University, San Bernardino) teaching masters students in the Counseling program.

Tina spent 4 years at the University of Illinois at Urbana-Champaign (UIUC), where for the last 3 years she was a Research Professor in the Department of Education Policy, Organization and Leadership in the College of Education. In this position, she taught graduate programs in Global Studies in Education and Critical Thinking. She also held a Ph.D. seminar on Michel Foucault. She remains an Adjunct Professor at UIUC.

Prior to her career in academia, Tina was a secondary school teacher, school counselor, and Head of Department (Guidance). She is MNZAC, a long-standing member of the New Zealand Association of Counsellors having been involved on both the Auckland subcommittee and the NZ membership committee.

Academic Literacy Across the Curriculum

Jon-Philip Imbrenda¹ and Michael W. Smith²

Introduction

This entry examines academic literacies across the curriculum with respect to the orientations scholars have developed to the nature of the knowledge of reading and writing required for academic literacy and to the extent to which that knowledge is generalizable across different texts and different contexts. The focus is on reading and writing here as these are the most prevalent modes of participation in academic settings, recognizing both that students engage in a wide variety of other literacies outside school and that both in-school and out-of-school literacies could be enriched by a more permeable boundary between those settings. The questions of if, when, and how learners transfer or appropriate knowledge across domains and contexts has long been of interest to

educational psychologists, and research in academic literacy has paralleled those debates (Smagorinsky and Smith 1992). Three distinct understandings have emerged: academic literacy as general knowledge, as genre-specific knowledge, or as membership in a community of practice. How teachers and researchers view the nature of literacy across classrooms, disciplines, and content-areas is largely a function of how they have been informed by the three views. Each differs in its assumptions toward the nature of knowledge itself, the extent to which literacy embodies a kind of knowledge, and the manner in which literacy instruction should be approached. Drawing upon influential research and theory, this entry will describe each view and address its theoretical and pedagogical assumptions.

The General Knowledge View

The governing assumption behind a general knowledge view of academic literacy is that the robust strategies employed by expert readers and writers are common across domains and disciplines. The general knowledge view has proven to be highly influential in the structure and organization of conventional educational curricula, as evidenced by the extent to which English and language arts classrooms are held as the primary arenas in which reading and writing are taught, as well as the role of first-year composition courses across most universities as the chief means of preparing incoming students for the demands of reading and writing that will follow in their later coursework. It is assumed that what students learn in such settings will transfer to other contexts. Teachers and researchers who embrace a general knowledge view hold an *a priori* belief that reading and writing, as forms of activity, involve a set of essential processes that operate independent of the specific type of text being read or written or the context in which the activity is being carried out. Although recent, large-scale reform efforts have begun to consider the role of discipline-specific approaches to reading and writing in the design of curriculum and instruction, the general

knowledge view is still largely dominant in educational practice.

General knowledge views of academic literacy are rooted in an understanding of learning as individual cognition. For example, driven by Piaget's notions of accommodation and assimilation, schema theory (Anderson and Pearson 1984), one manifestation of the general knowledge position, articulates the role of individual cognition in the processing of written text. Comprehension is understood as the interaction between a reader's existing knowledge, or schema, and the new knowledge encountered through the activity of reading. A schema represents a summation of abstracted knowledge that organizes what is known about a collection of cases which may differ in their particulars. To understand what has been read is either to encode it onto a mental representation that matches with a preexisting schema or to modify a preexisting schema so as to accommodate the new information. Anderson and Pearson (1984) demonstrate the schematic basis of reading comprehension through a series of experiments in which readers are presented with deliberately ambiguous texts. In one example, the text could be read as a description of a prisoner escaping a cell or as a wrestler escaping a hold. The initial inference made by each reader to determine which schema to activate dictates how subsequent information is processed. Schema theory reflects a general knowledge orientation toward literacy because it takes as its locus of concern the individual reader's cognitive equipment as opposed to the linguistic demands of specific text types or contextual circumstances surrounding the activity of reading. Whereas the nature and variety of schema will differ across individuals, the general knowledge position holds that all readers employ schema in similar ways.

In writing theory, the role of individual cognition as the basis for general knowledge is most clearly reflected in cognitive process models that describe the mental systems involved in the composition of a text. By analyzing a series of think-aloud protocols carried out by writers of varying degrees of expertise, Flower and Hayes (1981) developed a dynamic model for the writing

process as the interplay of the task environment, the writer's long-term memory, and the various cognitive activities involved in the actual writing of a text: planning, translating, and reviewing. By categorizing the cognitive elements of the writing process, scholars compared the strategies employed by expert writers with those employed by novice writers, revealing, among other things, valuable insights into how writers set and adapt goals, anticipate audience needs, and make micro-level choices about style and diction. As a result, the emphasis of composition instruction shifted from product to process. Learning to write could be framed as developing declarative understandings of the elements of the process coupled with facilitated opportunities to engage the process across a variety of tasks. Although differences across writers and tasks invite different ways of engaging the cognitive processes involved in writing, the processes themselves are essentially the same according to the general knowledge position.

General knowledge views of academic literacy have given rise to the importance of metacognition as a distinct aim of both research and instruction. Guided by the belief that students develop as readers and writers when they approach texts with the appropriate schematic resources and master the robust strategies employed by experts, research design and classroom practice have introduced methods for making such strategies visible artifacts of analysis and bodies of content. Teachers and scholars have become just as interested in how a text has been read or composed as they are in the resulting understandings or written products. The underlying hope is that, if literacy involves a set of universal processes, those processes can be named, taught, practiced, and transferred.

More recently, scholars in composition have called into the question the universality of literacy processes while still maintaining a general knowledge orientation toward composition instruction. Downs and Wardle (2007) argue that the best approach to composition instruction is one in which inquiry into writing itself is the curricular focus. In other words, the field of writing studies should be the central topic of a writing course. Taking as their framework the notion of threshold

concepts – discipline-specific concepts that must be mastered before one can engage in the actual work of a particular field – Downs and Wardle (2007) assert that the general knowledge of writing most relevant and useful to students involves key understandings of writing itself: that it is highly contextual, that written texts mediate activity, that reflection is a part of the writing process, etc. While several widely adopted textbooks suggest that this view has gained uptake among university writing programs, there is less evidence that middle and secondary classrooms have developed comparable interest. However, the work exemplifies efforts to make general knowledge approaches more compatible with genre-specific and communities of practice views of academic literacy.

The Genre-Specific View

Critics of the general knowledge view oppose its focus on individual cognition as the primary agent in literate activity. They argue that literacy is not solely a cognitive phenomenon – it includes social, cultural, and historical forces that shape the habits of mind and patterns of reasoning that involve written texts. One such view focuses specifically on the social functions carried out by typified forms of texts, or genres. While broad similarities among text types such as narrative or expository are visible on a macro-level, genre theorists attend to the microlevel differences among text types within these broader categories. For example, even within the broad category of narrative, there are key differences in the forms and functions of allegories, ironic narratives, epistolary novels, etc. Because they are socially constructed, microlevel genres reflect a specialized kind of knowledge that cannot easily be generalized across contexts, especially in situations where different genres have few similarities, or with genres that operate within esoteric communities, such as social science reports. Consequently, advocates of a genre-specific view of academic literacy favor the analysis of specific genres in order to identify the strategies most relevant to reading and writing particular kinds

of texts. Literacy, in this sense, is not a kind of general knowledge but a repertoire of task-specific proficiencies.

Traditionally, genre studies aimed to classify text types according to shared rhetorical elements. Miller (1984) first theorized genre as a representation of conventionalized social purposes. Typification – the patterning of text types over time – is a cultural process through which social action can be carried out. Rather than viewing genre as a function of the formal properties of similar texts, it is understood as a level of meaning in which personal, idiosyncratic motives are mediated through typified, rule-governed textual structures. Genre is rhetorically significant because it mediates social action: it is a set of normative, interpretive rules that allow for cultural artifacts to carry meaning. For students, genres are the vehicles through which they can participate in the literate activities of the classroom community.

Genre-specific orientations toward reading examine the relationships between the conventional features of particular text types and the interpretive strategies readers bring to those text types. Understanding a written text is neither a strictly objective matter of correctly decoding the words on the page nor is it a strictly subjective matter of the word's potential to evoke a response. Instead, it is an act of coordinating the autonomous elements of the text itself with the readers' capacity to arrive at culturally viable understandings. According to Rabinowitz (1987), culturally viable understandings are genre-dependent. Different genres, he argues, invite and reward different interpretive operations. He details how authors count on shared understandings of genre-specific rules as they play out across different types of texts. Rabinowitz (1987) offers a metaphor to make his case. Reading a text, he proposes, is like building a swingset. Given the right parts, the task is easily accomplished as long as the builder knows what it is he or she is building. If the builder is given the parts without knowing what it is he or she is meant to assemble from them, the task becomes far more demanding. Comprehending or understanding a text is a reflection of the reader's familiarity with the type

of text being read and his or her capacity to attend to the appropriate details accordingly.

Scholars from the Sydney School have championed a genre-specific approach to the study of writing. Working from a functional linguistics framework, they construe genre as a configuration of meanings realized through language (Martin and Rose 2008). Written texts are approached with respect to their functional purposes in cultural activity. Such purposes operate paradigmatically – the organization of language enacts culture because it reflects the choices a writer makes among the options available for making meaning within a diverse, but ultimately bounded, system. Language realizes culture on three dimensions: interpersonal, ideational, and textual. The interpersonal dimension enacts social relations among interlocutors. The ideational dimension construes activity through discursive patterns. The textual dimension organizes the flow of information with respect to the mode of communication. Taken together, the three dimensions coalesce into patterns which thereby form integrated systems, or genres. Martin and Rose (2008) characterize the taxonomical insights gained from this approach as mapping culture. Pedagogically, the aim is to develop systematic understandings of genres so that they can be taught explicitly to primary school students to prepare them for the types of writing they will be expected to do in secondary school.

Teachers and scholars working from the general knowledge position seek to identify procedural understandings that are robust across different texts and tasks. Teachers and scholars working from a genre-specific position instead seek to identify particular strategies and structures called for by particular text types. Such analyses yield instruction designed to provide students with a repertoire of task-specific proficiencies to aid them across a range of academic settings.

The Communities of Practice View

A third approach to academic literacy across the curriculum reverses the focus from the individual

learner to the context in which learning takes place by foregrounding the nature of participation in the social activity of academic life and shifting genre-specific knowledge into the background. In this sense, genre-specific knowledge is seen as a product of social participation rather than the gateway into such participation. Literacy is not as much a matter of proficiency with specific text types as it is a matter of understanding the values, customs, and conventions of communities in which reading and writing are central activities. Such understanding develops through acculturation into communities of practice. A primary belief held by scholars working from this tradition is that knowledge is always situated in context. Whereas the general knowledge view pursues universal process that is essential to the activities of reading and writing regardless of the context in which those activities are being carried out, the communities of practice view reject the possibility of such universal processes because thought and language are fundamentally social and their origins are rooted in lived experiences rather than cognitive processes.

The term communities of practice, as it applies to literacy theory, is attributed to Lave and Wenger (1991), whose ethnographic studies of apprenticeship among tailors in West Africa highlighted the impact that participation in communities has on literate activity. They observed a kind of learning that was rooted in everyday, informal activities as opposed to the formal, decontextualized approach to learning dominant in schools. As a result, they came to understand learning as an aspect of how the nature of participation within communities of practice changed over time as participants developed mastery of the specific, ongoing, interdependent activities that comprised the communities in which they were situated. Powerful learning, they argued, resulted from legitimate peripheral participation in these day-to-day activities. Communities of practice must endow learners with positions of relevance through which they can gain access to full participation as their roles in the community change over time. Consequently, general knowledge develops as a product of situated practice, not vice versa.

Scholars associated with the New Literacy Studies have embraced a communities of practice view in their ethnographic studies of literacy across a wide range of cultures and communities (Street 2003). Literacy is understood not as a discrete phenomenon but rather as a means through which social activity is mediated by texts. Hence, the object of study is not literacy as a set of processes nor is it the nature of text types; rather, the focus is placed on *literacy events*, or social activities carried out by participants in a community of practice in which reading and writing serve as a mediational means. Street (2003) problematizes an emphasis on individual learners in literacy research by distinguishing between *autonomous* and *ideological* models of literacy. An autonomous model of literacy is analogous to a general knowledge view in that it assumes literacy is a universal set of processes which operate independent of context and promote positive cognitive outcomes. An ideological model, on the other hand, begins with an assumption that literacy is not a neutral set of skills and proficiencies but rather a social practice embedded in socially constructed ideological principles. Street (2003) introduced the term *literacies* to reflect this distinction. What constitutes being literate in a culture reflects the epistemological beliefs of the dominant forces within that culture. Literacy, in this sense, is always a contested terrain in which tensions between dominant and nondominant ideologies play out. Members of communities who hold nondominant orientations toward reading and writing must either submit to the dominant ideologies or develop inventive ways to hybridize the literate practices ushered through these dominant ideologies in response to local circumstances. For this reason, a large body of work stemming from the New Literacy Studies involves generating rich ethnographic portraits of local literacy practices in order to better understand the underlying ideological conflicts that arise from the institutional demands of formal schooling.

It is uncommon for scholars who embrace a communities of practice view to focus solely on either reading or writing, as doing so implies a putative division between those activities that

competes with an interest in literacy events as holistic occurrences through which literate practices can be inferred. Bazerman (1988) offers a notable exception in his seminal, genre-based analysis of the experimental report in science. Although he sets out to characterize the rhetorical features of the genre and the extent to which they reveal how writers of scientific reports utilize conventions of language to respond to empirical exigencies, his analysis illuminates the predominant role of communities of practice in mediating the potential for written texts to convey meaning. Within communities of practice, readers and writers carry shared values, assumptions, and epistemologies that stretch beyond the words contained within a single text. Efforts to negotiate those shared assumptions largely inform the rhetorical options available to a writer. Experimental reports in science, widely held to be objective accounts of empirical facts, are instead very much social constructions themselves, shaped by the demands set upon them by the communities in which they are imbued with socio-ideological value. Communities of practice function as activity systems, mediating the production and dissemination of knowledge through written texts so as to reinforce their own values and purposes. A writer working within a community of practice does not merely reproduce a genre – he or she extends it in order to respond to immediate circumstances using the rhetorical apparatus available within that community. Consequently, in such a view, genre-specific instruction is limited because it does not carry with it the broader social purposes involved in writing. Genuine involvement with a community of practice is necessary to fully inculcate a student writer into the values, customs, and conventions that underline the creation of a text.

A communities of practice view of academic literacy across the curriculum affords a valuable lens into the extent to which perceived differences in literate abilities are in fact differences in cultural, ideological, and economic orientations toward written texts and their importance as mediators of social activity. By rejecting an autonomous model of literacy, reading and writing are

no longer viewed as skills or proficiencies individuals either possess or do not possess. Instead, the locus of concern is understanding ideological differences in what constitutes literacy and adapting institutional practices so as to accommodate those differences. However, two notable criticisms of the communities of practice view have emerged. First, in its tendency to emphasize the local, a communities of practice view risks ignoring the relatively common features of literacy as it plays out across different contexts. Literate practices often come to communities from the outside, and they bring with them meanings that extend beyond the perspectives of participants within those communities. Communities of practice may not refute the existence of universal literacy processes; instead, they may offer insightful variations on those processes. Secondly, few practical applications of a communities of practice view to formal education have gained feasibility on a large scale. Whereas central tenets and evocative discoveries gleaned through the general knowledge and genre-specific views have found their way into curriculum and instructional practice, the communities of practice view has proven more useful for uncovering flaws than for proposing viable solutions. Many foundational assumptions of the communities of practice view are incommensurable with the institutionalized routines associated with formal schooling, and a paradigmatic shift in the way that education is structured and implemented would be necessary to fully satisfy the multiplicitous view of literacy embedded within the communities of practice approach.

Conclusion

In short, scholars investigating academic literacy across the curriculum have been informed by significantly different theoretical perspectives. These different perspectives result in different foci of study, different methods, and different approaches to instruction. General knowledge views tend to result in studies that examine the processes by which readers and writers make meaning.

Instructionally, this view promotes an emphasis on teaching robust strategies and metacognitive reasoning. Genre-specific views tend to focus more on examinations of texts themselves in order to describe the key features that allow texts to mediate discrete social activities. Instructionally, this view favors analysis of specific reading and writing tasks in order to cultivate strategies specific to those tasks. Lastly, a communities of practice view tends to rely on ethnographic accounts of how texts mediate everyday activities. Instructionally, this view favors including a broad range of literacies in school curricula and fostering an understanding of and respect for the multiplicity of ways in which people use texts in their lives.

Adapting Pedagogy for Formative Assessment

Chris Harrison
King’s College, London, UK

Introduction

Assessment for Learning is an accepted approach to pedagogy in many countries where the purpose of assessment is to provide feedback and guidance to inform future learning. Both teachers and learners are involved, but ultimately it is the

learner that needs to take action. Adapting pedagogy to make room for feedback and action is a complex process that takes time and effort to evolve.

Classroom Assessment

Black and Wiliam's (1998) survey of evidence linking assessment with improved learning has significantly influenced how educators and policymakers have conceptualized classroom assessment over the last three decades. Within classroom activities, teachers are able to collect data on student understanding from the way learners answer questions, the questions they raise, and the quality of the artifacts they produce. If this assessment information is then interpreted and used by teachers, students, and their peers, to make decisions and take action to enhance learning, the assessment is termed formative. Interpretation and decisions can drive future planning and support student learning through feedback. In a classroom where assessment is used to primarily support learning, the divide between instruction and assessment becomes increasingly blurred and can disappear (Perrenoud 1991).

The emphasis on formative assessment being informal and part of everyday classroom activity rather than an episodic event of testing is captured by Klenowski (2009):

Assessment for Learning is part of everyday practice by students, teachers and peers that seeks, reflects upon and responds to information from dialogue, demonstration and observation in ways that enhance ongoing learning. (p. 264)

This definition also emphasizes the learner as active in the assessment process through their understanding of what is being learned and how quality is judged. This moves the learner increasingly into the foreground of classroom assessment, with implications for teachers.

This entry looks at ways assessment for learning functions in classrooms and the types of development and learning teachers engage in to strengthen their formative practice. It also considers some of the challenges teachers face when they attempt to make changes in practice. As such,

this entry provides insights in support of professional learning as well as greater understanding of formative assessment.

Assessment for Learning as a Pedagogy

As Black and Wiliam (1998) reported, it is difficult to imagine how assessment for learning (AfL) implementation can be treated as a marginal change in classroom activities, because it relies on strengthening feedback loops between learners and teachers and within learning groups. Creating a classroom environment where interactions between learners dominate often requires new skills and practices for both teacher and students. The nature of these changes is a key determinant for the outcomes for students, as formative work becomes embedded in new modes of pedagogy.

Teachers when introduced to ideas on AfL tend to work on a range of strategies that strengthen classroom talk both to improve how they probe and prompt learners in discussion and to help their students respond and interact with one another with increasing confidence. We know, from working on "wait time" (Rowe 1974) between teacher questions and accepting answers, that more students volunteer to answer and elaborate on their answers than previously. In some classrooms, the change is enormous, moving from single word answers from a handful of students to a purposeful discussion driven by several students.

Common to all AfL practices is the active involvement of students, whose role changes from passive recipients of knowledge to active partners in the learning process (Swaffield 2011). Students finding out what makes sense and developing ideas through self and peer critique through discussion encourage next steps in learning. In this situation teachers have to decide which of the many diverse student ideas and experiences are productive starting points for relating and navigating between everyday forms of knowing and those accepted and used within a subject domain (Bang and Medin 2010). Given this dynamic set of assessment information, the teacher can decide how to respond to students' current conceptual understanding of that topic. Importantly through

this approach, students can use feedback to evaluate their own and others’ work, learn from their mistakes, and learn to reflect on their learning. The goal of AfL is not however to eliminate mistakes but to keep them from becoming chronic and seen as inevitable (Stiggins 2007). When students make a mistake or realize something they have done is incorrect, it is part of the teacher’s role to restore their confidence and help them address the situation. This is part of the emotional dynamic and challenge of AfL.

Implementation of AfL Practice

We know that formative assessment is difficult to achieve, even in countries like England, where considerable funding and training has been put in place to support the shifts in teacher practice required (Looney 2007). Despite the investment in training materials, time, and money (e.g., DFES 2007), a report from school inspectors in England indicated that teacher practice was inadequate in 7 of the 43 schools sampled and good to outstanding in only 16 schools. The report noted that AfL practice was better established in primary than secondary schools and also that it was more established in English and mathematics than across the curriculum in both primary and secondary schools (OfSTED 2010). Even when schools valued the training and support provided, good practice in assessment for learning did not necessarily follow with teachers implementing strategies without consideration of how they were meant to work to strengthen feedback. In some cases, schools made decisions to introduce specific AfL strategies, such as traffic lights or comment-only marking, across all classes. Implementation differed markedly from teacher to teacher and failed to ensure consistency of principle while superficially achieving uniformity of practice (Harrison and Howard 2009). In addition, senior leaders did not maintain the momentum of implementation beyond the introductory stages, often moving on to other priorities before practice was secure. Clearly, the reasons for the failure of full-scale implementation are complex, affected by individual teacher conceptualization beliefs

and practices and by school systems. In essence, bringing about large-scale change in practice requires considerable effort, determination, and time for new ways of working to be understood by the individual teachers and for new practices to be recognized as valuable and successful by all those within the school community.

Teacher Approaches to Assessment for Learning

The King’s collaborative action research project on the effect of a yearlong trial of implementing AfL in secondary science and mathematics classrooms (Wiliam et al. 2004) categorized the 24 participating teachers into four categories based on their use of key AfL strategies. These categories were triallers, static pioneers, moving pioneers, and experts. Descriptions for each group are set out in Table 1.

Subsequently, the King’s AfL team have been involved in other classroom assessment projects with hundreds of teachers in primary and secondary schools (e.g., Harrison and Howard 2009; Black et al 2011). This enabled them at firsthand to observe the ways in which teachers adopt and adapt AfL strategies into their existing practice. While the initial framing of the four categories broadly holds, the team now recognize that it is not simply what AfL strategies teachers use but also how teachers use them as part of their classroom procedures. This has led the team to consider the changes teachers make to their practice, both

Adapting Pedagogy for Formative Assessment, Table 1 Types of Assessment for Learning Teachers

AfL teacher type	Description
Trialler	Teacher tries one or more AfL strategies with one class
Static pioneer	Teacher tries a few AfL strategies and decides on those that they will retain in their practice
Moving pioneer	Teacher who experiments with a number of strategies and begins to consider which work well and which need adapting or removing after a few attempts
Expert	Teachers who have established a number of strategies and can explain and demonstrate how these increase feedback loops between students and teacher and affect teaching and/or learning

Adapting Pedagogy for Formative Assessment, Table 2 Approaches to Assessment for Learning Pedagogy

Teacher type	Description	Teacher quotes
Conformists	These teachers often relate change in practice to their interpretations of policy or practice requirements from senior colleagues. They explain what they have introduced or changed within their teaching but give little consideration to why this might be useful or how they might use the strategy to benefit learners. Statements tend to be functional, procedural, and unproblematic	“We have a policy that like tells you what you need to do and so each activity has objectives and success criteria in your planning documentation and our headteacher checks these are in place.” (Stefan – Y6 teacher)
Strategy players	These teachers select or trial a specific AfL strategy that they can describe and also attribute the benefits for teachers or learners	“We get the children to us traffic light cups, one set per group, and this helps us see how confident they are when working on group tasks.” (David – secondary science teacher)
Checkers	These teachers focus on the tasks they have planned and use strategies to help them recognize successful completion of the task and indicate shortcomings or errors. Success criteria are used as a checklist rather than ways of describing quality performance, and this is evident in the atomistic way they feedback to students	“I mark their work against the success criteria and then use what’s missing or what they have got wrong to set a target for them to do their corrections.” (Eloise – secondary language teacher) “We decide the success criteria as a class and then check each of these off as pupils move through the tasks.” (Samara – Y6 teacher)
Involvers	These teachers believe that AfL provides the students with useful feedback and encourage students to compare ideas. They are keen on group activity and use peer assessment as a regular part of classroom activity	“Getting the children to work more collectively, swapping ideas and generally sharing so that they can learn from one another or even teach their peers something. I find this really helps.” (Gina – Y6 teacher)
Formative practitioners	These teachers see learning as a collaborative endeavor with students both supporting and assessing one another’s learning. AfL is seen as more than strategies to use and more as aspects of a teaching approach designed to benefit from feedback opportunities	“It’s about getting the kids to be good learners, to be willing to have a go and make mistakes which they learn from. It involves groupwork, talk for learning and lots of feedback both to me and from me and with each other.” (Stephen – secondary science teacher)

initially and as their practice evolves. The team also focused on how teachers explained and reflected on their formative practice and the reasons they gave for selecting a specific strategy, using the strategy in a particular way and/or deciding to change the way they worked with a strategy. By sifting and analyzing the data from teacher-researcher conversations during classroom visits, recorded in field notes, and in interviews typically given toward the end of projects, the team has framed five typical AfL teacher types (see Table 2.)

While the professional learning journeys of individual teachers varied greatly, teacher developmental trajectories generally began incrementally and then often halted at various points so teachers remained consistent in that AfL approach

for a considerable time. In some cases, this was the endpoint of the development within the time frame of the project. Most of the project teachers were either conformists or strategy players in the early part of a project as they tried new ways of working. Some teachers continued to show similar classroom AfL behavior throughout the project, remaining as conformists or strategy players. The majority of teachers, however, moved to a different AfL approach as the project progressed. What was particularly noticeable were the similarities in the factors that teachers attributed to their change in practice and the reasons given for not taking forward practice further. Some conformist teachers and strategy player teachers developed a checker approach;

the conformist teachers, however, never became involver teachers or formative practitioners. This was often because they did not believe that their students could play a more active part in assessment:

They (students) find peer assessment very difficult and whenever I try it, I end up marking it myself anyway. (Stefan – Y6 teacher)

While they (students) might be able to spot mistakes, most of my class wouldn't be able to give the correct word or grammatical idea and so the feedback is better coming from me. (Simone – secondary French teacher)

What was also of interest was how the checker teachers conceptualized knowledge. While they accepted the idea of a gap (Sadler 1989) between the anticipated performance and the actual performance, their conceptualization of closing the gap was to provide instruction as though knowledge came in incremental building blocks and to use a linear and procedural model of feedback (Torrance 2015). Their approach also suggests that improvement centers on closing the gap and completing a task rather than providing feedback that opens up an idea and stimulates further thinking. Indeed, much of the feedback provided by both conformist and checker teachers was presented as corrections with either the correct words or numbers given or an example provided for the target. This approach fits with Torrance and Pryor's (2001) view of convergent assessment, where the aim of the teacher is to check that students have arrived at a predetermined endpoint for that task, such as "used the correct tense" in a language lesson or "can list all the prime numbers below 20" in mathematics. On the other hand, some of the strategy player teachers did move on to become involvers or formative practitioners because they were more willing to share the control of learning with their students. Their view of learning was much more within the socio-constructivist domain, where they considered how students might be helped to interact more with one another to find new solutions or ways of working. This approach fits with Torrance and Pryor's (2001) view of divergent assessment where the assessment approach provides feedback

to encourage students to think further and develop ideas. The following two examples demonstrate divergent assessment feedback:

How was the Pharaoh's role different to that of a citizen in ancient Egypt? How did he demonstrate to his people and his enemies that he was powerful? (Year 6 History)

Why do you like the use of alliteration in this poem? (Y9 English)

Summary

AfL has become an accepted part of pedagogy in most UK classrooms but the degree to which it supports learning differs from classroom to classroom. There remains a need to raise teacher awareness of what is involved in an effective AfL approach, what formative assessment is, the important role students play in this process, and how AfL can be incorporated into teaching. In many cases, this will require teachers to (re)consider their beliefs about learning and the intricate ways both assessment and teaching weave into this (Harrison 2013). Such changes need peer collaboration and support from the school and professional development community over time and not simply the introduction of the new ways of teaching.

The main difficulty for the teacher who wishes to develop AfL practice is that they cannot simply add new strategies to their current practice. Instead, they need to gradually make changes to their current practice to allow new ways of working to slip into class procedures and systems, while, at the same time, supporting their students in developing new ways to work with peers in the classroom. This iterative process takes sustained effort to introduce and time to implement, and so teachers need to be convinced that such changes are necessary and likely to be fruitful in future lessons.

Adult and Continuing Education in the Nordic Countries: *Folkbildning*

Elinor Hållén

Uppsala University, Uppsala, Sweden

Synonyms

Adult education; Character formation; Civic education; Emancipation; Popular education; Social movements

Introducing *Folkbildning*

This entry discusses the Nordic variety of *non-formal adult education* or *popular education*. These English terms emphasize different aspects of this Nordic tradition. It is education for adults, including young adults. Unlike the formal school system, it is not bound by a set curriculum; it is therefore more flexible in its capacity to reflect changes in society. Furthermore, it is entirely elective. Although *nonformal adult education* is the term most commonly used in referring to this form of education in English, *popular education* captures a salient feature in much of this tradition; it is typically geared particularly to those with little education or low social status. It aims to be not only *for* the people but also *by* the people; it is the people taking the education of themselves and their fellow men into their own hands.

It makes sense to call this a Nordic tradition since the national varieties have common historical roots and share many key features. This is reflected in the descriptions. The Danish and

Norwegian *folkeoplysning/folkeopplysning* can be translated as “enlightenment of the people” and the Swedish *folkbildning* to “cultivation or formation of the people.” In Finnish, two names are used, *kansansivistys*, the equivalent of *folkbildning*, and *aikuiskoulutus*, meaning “adult education.” The Icelandic word *fullorðinsfræðsla* means “adult education.” Due to limitation of space, focus will be on the Swedish tradition, together with remarks on Denmark, where Nordic nonformal adult education was born. Swedish *folkbildning* is here chosen as the prime example because it is the most closely allied with the State, raising the problem regarding the autonomy of the institutions of *folkbildning*, a central issue in higher education. The Swedish description *folkbildning* will be used to refer to the Nordic tradition in general.

***Folkbildning* as Philanthropic Emancipation and as Popular Education**

In the nineteenth century, Enlightenment thought reached the people of the Nordic countries in the form of new ideas and ideals for the education of the common man. The movement can be roughly divided into two initial stages: *folkbildning* as philanthropic emancipation and *folkbildning* as popular education.

The first wave of Nordic *folkbildning* was initiated by a fraction of the bourgeoisie who, inspired by Enlightenment and Romantic thought, wanted to liberate the masses from oppression by educating them. The mission, inspired by seventeenth century philosophy, was to cultivate citizenship and civic virtues. At the heart of this Enlightenment project lays a conception of human beings influenced by British empiricism, especially by John Locke’s ideas about natural law. Locke saw certain human rights and values as inherent in human nature and as universally cognizable through human reason. According to Locke, no human being has a right given by nature or an almighty God to rule over someone else. Instead, the Law is something rooted in each

individual; thus every man should partake in and be responsible for decisions regarding society. According to this ideal, the rational and enlightened citizen ought to be capable of critically examining different alternatives and autonomously taking a stand on them. The idea of natural law underlies the English Bill of Rights, the French Declaration of the Rights of Man and Citizen, and the American Declaration of Independence. The Western conception of democracy is thus founded on the idea of natural law, in which the rights of the individual area concern for all other citizens.

Conservatives, often influenced by Romantic ideals, challenged the philanthropy of bourgeois radicalism. The first attempts at *folkbildning* in Sweden were directed at the farmers, but since they were considered archetypical Swedes, many wanted the farmer to stay simple and untainted by urban decadence, industrialism, and the Enlightenment (Gustavsson 1991, p. 55). But Romantic thought also became an inspiration for *folkbildning* to move beyond emancipatory education of the lower class by the higher. Jean-Jacques Rousseau’s *Émile* introduces an ideal for education where the young learner actively searches for knowledge guided by his own needs and motivations, while having nothing but his own previous experiences as a knowledge base. This idea, in which the search for knowledge and cultivation originates in and emanates from oneself, is the backbone of *folkbildning*; it is cardinal to the pedagogy of folk high schools and forms the core of study circles. The ideal contains an implicit critique of philanthropic projects of *folkbildning* while, as will be discussed later, cherishing the ideal of *folkbildning* as character formation.

Folkbildning as popular education begins with the education of the people – the peasants, the workers, and those without property – and aims at challenging the social order. In it the ordinary man takes education and *Bildung* into his own hands, redefining those concepts in the process (Compare Crowther 2013, p. 262). At the turn of the twentieth century, new peoples’ movements

arose and proliferated in Sweden. The most influential of these were the labor, temperance, and free church movements, all which became driving forces in the political and social democratization of Sweden. At the time, the public school system was relatively undemocratic; the majority had no access to education beyond mandatory schooling for 6 years. Within the peoples' movements, *folkbildning* was created as an alternative educational model. Among its most salient features, distinguishing it from the public school system, was that *folkbildning* was "fri och frivillig" – nonauthoritarian, unregulated, and voluntary. Moreover, *folkbildning*, particularly as it arose within the labor movement, was popular: the people should decide for themselves what to study, what to teach, and what it is to be taught.

The Folk High School and the Study Circle

The Danish humanist and pastor N. F. S. Grundtvig played a leading role in the foundation of the folk high school. He criticized traditional instruction for having failed to bring about "common sense about that which lies nearest to us: about our own nature, conditions in the fatherland, and what is best for the common interest" (Grundtvig 1838, p. 88). Grundtvig wanted the Danish citizen to receive a Nordic education. By reading Nordic authors and reading about Nordic history, he would learn to understand himself better and find an inroad to knowledge about the rest of the world. Nationalism is a distinctive trait of Danish *folkeoplysning*, due in part to the fact that Grundtvig was a strong advocate of National Romanticism and in part to the historical circumstances in which the tradition arose. The first folk high school opened in Rödning, North Schleswig, in 1844. This province had a mixed population of people with Danish and German ancestry. Around 1830, tensions between these groups arose which triggered a growing feeling of belonging with the Danes as ethnic group in the people of Danish descent. Grundtvig had ideas not only on what should be taught but also on how to teach. Teaching should be a means for spiritual as well as

historical awakening, and this ideal should permeate the planning and the pedagogy of the schools. The students should live on school premises and form good and nonhierarchical relationships with their teachers. Ideally, the school would have beautiful natural surroundings. The teachers should be free in their choice of pedagogy and materials. The folk high schools should be for young adults since, Grundtvig believed, they were best suited for learning (Holmström 1886, pp. 20–24).

The Swedish folk high schools were modeled on the Danish ones, but the Swedish tradition of *folkbildning* clearly stands apart from the Danish, as well as the Norwegian and Finnish. This seems largely due to differences between the nations in terms of political power at the time when *folkbildning* arose. Sweden was rather powerful in the nineteenth century, and the Swedes, unlike their Nordic neighbors, enjoyed national sovereignty as an ethnic group. Thus, when *folkbildning* arose in Sweden, it was not cloaked in nationalism, nor did Swedish national culture, literature, and history have the same elevated status in it as they had in Danish *folkeoplysning*. *Folkbildning* was not an ethnic issue in Sweden. There were, however, great political and social inequalities between the classes, which were slowly being acknowledged and addressed. In 1866, the Riksdag of the Estates was abolished, and the peasants won greater influence over the municipality. When *folkbildning* arose in Sweden, it was a response to this development. Holmström argued that the peasant became conscious that, from now on, he must *see* himself as a citizen and that the peasantry must be abolished as social class (Holmström 1886, p. 285). Some farmers saw the need for peasants to learn more about civic affairs, and one of the first Swedish folk high schools, Hvilan, was founded with this aim in view.

At the turn of the century, Oscar Olsson – who was later to become Social Democratic Member of Parliament – proposed a study form based on self-teaching to the Swedish Order of Good Templars. This started the extensive and widespread activity that study circles have become. A study circle is a small group of people joined by a

common interest who meet regularly to partake in an educational activity: discussing a text, learning about union rights, or developing their skills in a certain handicraft. Olsson discusses the choice of name – study circle – as perhaps misleading, since they did not primarily aim at the acquisition of knowledge but at *Bildung*, i.e., character formation and sound judgment. Since this included the development of good citizenship and insights into culture, the social aspect was important. The study circles succeeded better in bringing education to the people than did the folk high schools, since there were hardly any costs involved, and the meetings did not take much time from work. They were also to a much greater extent expressions of an increasingly influential idea that one should take education into one's own hands. Olsson rejected the idea that *folkbildning* should be objective and neutral, arguing that if one wants to accomplish something through *folkbildning*, one must start from the groups people actually make themselves, based on interest, vocation, and affinity. The study circle was a break with philanthropically influenced *folkbildning*, which was aimed at the people but over which the people had no influence. Olsson describes philanthropic *folkbildning* as a spiritual soup kitchen for those in need (Arvidsson 2005, p. 19).

In 1907, the Swedish Parliament decided to set aside government grants for the purchasing of books by study circle members. They could only be granted to national organizations, which spurred the development of the institution of study associations. The first study association, *The Workers' Educational Association*, was founded by the Social Democrats, the Swedish Trade Union Confederation, and the Cooperative Association in 1912.

***Folkbildning* as Civic Education and as Character Formation**

Social and political interests were decisive factors in the founding of folk high schools and study circles in Sweden. *Folkbildning* had an important role to play in forming new layers of educated citizens who could partake in the democratic

government of the country. However, the tradition in which *folkbildning* is primarily seen as civic education has always coexisted with a tradition that focuses on the individual and his character formation. This tradition was most strongly advocated in Sweden by the philosopher Hans Larsson and the author Ellen Key. It starts with the conviction that education should take the individual and his interests as its starting point and that it should aim at the integration of the faculties of reason, emotion, and will. In a well-integrated personality, moral cultivation is paired with the cultivation of reason to form a conscientious person. Analogously, a cultivated person is not a person who has been trained to learn specific skills or specialized knowledge and is therefore useful to others, but one who has appropriated what he has learned to form a deeper and more integrated character. Although this tradition focuses on the individual, it sees the individual as part of the greater whole – the development of the individual as part of the development of humanity – and it is permeated with the humanistic ideal that every citizen shall take equal part in society and in cultural life.

Enlightenment ideals are strong in this tradition, and Immanuel Kant's voice reverberates with particular resonance in Larsson's characterization. In Kant's philosophy, as well as in Rousseau's, activity is the basis for knowledge. Kant's epistemology was revolutionary in that it changed our view of how knowledge is attained: knowledge does not consist of sense impressions statically received by reason, nor is it a product of reason alone, but sense impressions are structured by an active categorizing and conceptualizing reason to form knowledge. *Folkbildning* is greatly influenced by the idea of knowledge formation as an active process. It promotes an active search for knowledge initiated by the knowledge-seeking subject himself and is critical of emancipatory attempts at education in which knowledge is something that one learns passively and unreflectively. Instead, and in line with Kant's call in *What is Enlightenment?* – "Have the courage to use your own understanding" – people are encouraged to select what they find worth while learning and to use and develop their reason

actively in pursuit of knowledge and judgment to become morally responsible persons and citizens.

In the study circles, the traditions of civic education and character formation came together. Some study circles had a clear political content and aim and can be seen as expressions of a quiet social and political upheaval, while most were for learning and self-development through self-study, discussion, and shared responsibility in the democratic organization of the circle. Olof Palme, former Prime Minister and Leader of the Social Democratic Party, described Sweden as “to a substantial degree a study association democracy,” saying further that it is in study associations that generations have educated themselves in critical judgment, to belief in reason without loss of idealism in formulating their goals, in cooperation with others. Social change has often been set in motion in the study circles (palme 1969, p. 299).

***Folkbildning* and Its Relation to the State**

Today Swedish *folkbildning* is strongly tied to the State, which is its main source of funding. It stands out from its Nordic counterparts in this respect. *Folkbildning* is highly regarded by the Swedish State. It is seen as a cornerstone in a well-functioning democratic society made up of educated, reflective, and capable citizens; thus, State funding has grown ever more generous. Being the main financier, the State has great influence over the activities and functions of the study associations and folk high schools. Many have regarded this economic bond as problematic, and it has been argued that it puts Swedish *folkbildning* in a paradoxical situation (von Essen and Sundgren 2012). *Folkbildning* has its roots in people’s movements, in civil society where people come together in joint activities for a common cause without interference from the State or other authorities. Civil society is thus put in a position to examine the authorities critically. Today Swedish *folkbildning* depends for its survival on State funding. How does this effect *folkbildning* as a critical body?

There is an agreement between the providers of *folkbildning* and the government that *folkbildning*

should be free from State regulation. It should, as previously mentioned, be nonauthoritarian, unregulated, and voluntary. More specifically, this means that the State should not try to influence either the activities, the form, or the intellectual content of the bodies that make up *folkbildning*. Taken together, these stipulations could allow *folkbildning* to retain some of its autonomy. The government, however, has certain expectations as to what *folkbildning* should strive for, as well as how it should respond to societal changes and needs. In collaboration with Swedish *folkbildning*, the government sets up four aims that are to form the backbone of the activities of study associations and folk high schools. When the government evaluates these institutions, these aims form the basis for the evaluations. First and foremost, *folkbildning* should support and arrange activities that contribute to the strengthening and development of democracy. It should further contribute to making it easier for people to take control over their situation in life and engender engagement for taking part in the development of society, contribute to raising the level of education and *Bildung* in society and to evening out differences in levels of education, and contribute to raising interest and increasing participation in cultural life. But Swedish *folkbildning* is given further directives by the government. For example, the study associations are now expected to expand the Internet-based study circles. When assessment of the quality of the activities of study associations and folk high schools is based on the four aims and other directives given to *folkbildning* by the government, and this is used as the basis for continued funding, one may ask: How free *folkbildning* is? What does non-authoritarian and unregulated mean under these conditions?

In 1990, the Social Democratic Government established that the providers of *folkbildning* shall define the goals for the activities, while government and Parliament shall define the goals for grant allocation (Proposition 1990/91:82, p. 6). However, the economic governance of *folkbildning* and the governance of its activities are not separable in practice. More State funding has been set aside for certain activities and

pedagogical forms than for others, and this has influenced the study associations to expand in those fields at the cost of others (Sandahl and Sjöstrand 2014, p. 93). While *folkbildning* is said to be free to determine its own activities and pedagogy, in practice, State funding and its related guidelines exert powerful influence over the content and form of these activities (Hållén 2016).

Given the ambition and reality of Swedish *folkbildning*, the form it has taken, and its extension today, it is difficult to imagine an alternative to State funding. One of the most fundamental values on which *folkbildning* is built is that it should be available to anyone. Cost should not be an obstacle. While the first folk high schools were largely paid for by private donations, this is no longer an option. Some researchers argue that, in spite of obvious difficulties, the State is a natural ally for *folkbildning* in our time since they can together challenge the market interests which threaten to undermine the State, by reinvigorating the public sphere, for example, and keeping open alternative options to the language and values of the market (Crowther 2013, p. 260).

Aesthetic Education

Felicity Haynes

Tingrith, Margaret River, Crawley, WA, Australia

Synonyms

[Aesthetics](#); [Beauty](#); [Complex](#) [pragmatism](#); [Transcendentalism](#)

Aesthetic education seems to be most easily defined by what it is not. It is not the teaching of logical form or matters of fact, and it is not

satisfied to remain at the level of surface text. Generally, aesthetics seems to be the defining characteristic of the arts, with which it is usually identified.

Monroe Beardsley saw the central task of aesthetic education as the improvement of taste, claiming that this required the development of two dispositions: (1) the capacity to obtain aesthetic gratification from increasingly subtle and complex objects that are characterized by various forms of unity and (2) an increasing dependence on beautiful objects as sources of aesthetic satisfaction. Beautiful objects for him were inherently beautiful. They were perfect. They adhered to the rules of good composition. They allowed people to feel pleasure when they contemplated the objects disinterestedly. They caused pleasure due to intrinsic properties such as color, line, shape, proportion, harmony, symmetry, etc. They revealed a spiritual force in the universe. They were whatever pleases people of good taste, and they had properties to which people respond with love.

Somewhat circularly, Beardsley claimed (1982, p. 81) that a person was having an aesthetic experience during a particular stretch of time “if and only if the greater part of his mental activity during that time is united and made pleasurable by being tied to the form and qualities of a sensuously presented or imaginatively intended object on which his primary attention is concentrated.”

This classically traditional definition makes explicit its assumptions of intentionality, holistic sensuous qualities, imagination, and form but it does not address the question of how or why we would want to teach it in schools, a topic which has only been considered in the last 30 years. Transferred to the arts, it requires that production of or performance in the arts is intentional rather than divinely inspired or genetically imposed. The question of taste alone is highly contentious and one would wonder whether beauty is the ideal to which students are directed these days. There seems to be an assumption that through intentionally creating artworks which “come together appropriately” (as opposed to craft), students will come to develop a disposition to experience the aesthetic moment. But in many schools this aesthetic moment is ignored. The emphasis is

given to the product *qua* product and to the documentation of the student’s learning process through production portfolios or visual diaries. The rational reflection and self-consciousness of discipline-based art education marginalize the aesthetic experience.

It is often assumed that the aesthetic experience is equally marginalized in schools by prevailing cultural pressures of accountability and pragmatism and the dominant functionalism of education. Arts are justified in the curriculum only because they pass on the cultural heritage of our society; or because they train students in skills that might lead to a worthwhile occupation as a carpenter, musician, or painter in adult life; or even because they might decrease social malaise and alienation by making leisure time more enjoyable.

Such functionalism assumes that progress is only possible if there are measurable or demonstrable outcomes. The arts become more accountable as progress is measured in the number of products or performances. They are therefore presented in a theoretical language of criticism within which they can intentionally produce works of art. Such theoretical structures provide the frame and standards through which students can be graded and against which they can evaluate other works of art or arts performances. However, whether such a theory is testable, worthwhile, or even possible has rarely been considered. On formalist assumptions of aesthetics, it is sufficient for it to be internally coherent.

Where theories are not grounded on evidence, they proliferate, and the arts world slides into a cultural relativism of movements. Curriculum reformers bypass such contextualism by requiring a more solid foundation for evaluation. Rarely is this an educational one. As Danto said, when art becomes confused about aesthetic standards or discards the guiding standards of representation or artistic skill, the guiding value will become commercial, making the arts into a commodity in which the price or audience an artwork commands becomes the criterion of its success. So education in the arts becomes accountable in terms of the employment status of its graduates, the salary they can command, even their visibility in large museums, theatres, and the press.

Most aestheticians react to this as if a fundamental category mistake has been made. One cannot reduce the aesthetic to a number, or even to its pragmatic function. Success in the arts is so contextually dependent that one could never measure it by objective standards. It would be like trying to measure love or happiness, which are felt states rather than measurable products. Artists may earn money making artworks or performing, but that is not why they do it and that is not why we teach it in schools.

To formalists like Beardsley (1982) and Dickie (1983), if arts education was to be aesthetic, it had to be “disinterested.” “Art for Art’s sake” has become something of a cliché, especially at a period where political hegemonies seem to drive all. If the arts were to be a “discipline” in a Hirstian forms of knowledge sense, they would derive their identity from their formal structures, their ability to represent transcendental values of Beauty. Many drama and visual arts teachers tacitly assume the notion that besides aesthetics, arts are defined by their representational value at least in imitating Ideal form through mimesis. Music teachers particularly refer to the aesthetic formalism of Clive Bell (2015), based almost on Pythagorean notions of divine harmony.

An attempt to bring formalist transcendentalism closer to a physical reality was made by psychologists like Arnheim (1969) and Gombrich (1963), by naturalizing form in the brain through genetic structures. In his theory of multiple intelligences, Howard Gardner (1983) has raised the status of aesthetics in music by identifying it as a biologically inherited trait. These presumptions operate still within a modernist frame, making aesthetic experiences essentialist rather than politically and culturally contingent.

The formalist position runs the risk of retreating into a sublime essentialism that has nothing to do with the sordid or ugly, the political or mundane. The discovery that aesthetic standards presented as timeless and universal are in practice neither timeless nor universal – that they largely reflect beliefs and values typical of European patriarchy – has led to a more critical, historically grounded analysis of artistic concepts, institutions, and practices in general. Dickie

(1983) and Danto (1981) particularly remind us of the institutional presence in the arts, that their values are defined within a changing social context and that in the twentieth century at least, formalism is either trite or empty. The grounding of aesthetics must take a different form in a postmodern era.

The disappearance of the grand narrative has resulted in a broader and deeper understanding of the many social and cultural variables that contribute to prevailing notions of taste, aesthetic value, and artistic genius. As such arts teachers are now involved in helping children to enter aesthetic awarenesses not only of their own cultures but those of others from the past and present. To what extent this crossing of and comparison between cultural paradigms is possible has not been much debated in teacher training institutions.

Other barriers have been rendered invisible in educational programs, especially in the seamless construction of a learning area called the arts differentiated from languages, science, social science, and maths. What is thus differentiated can vary quite dramatically, with uncritical selections made variously from the performing arts, design, music, literature, visual arts, film, painting, sculpture, drama, dance, poetry, architecture, and jewelry-making. Different theoretical assumptions drive the selection according to the weight placed on self-expression (especially by psychologists), technical skills, beauty, aesthetic performance, cultural conformity, or originality. Could the integrating quality be a notion of aesthetic response?

Beardsley (1982), Osborne (1970), Weitz (1956), and others would say yes, and a brief history of the development of the arts area indicates the aesthetic assumption that works of art are still believed to have the capacity to induce higher levels of worthwhile experience which justifies their inclusion in the curriculum. Learning in the arts is “fundamentally experiential, creative, and developmental and must involve students in perceiving, transforming, expressing and appreciating,” as if these aspects somehow contained and defined the aesthetic. No use for drama teachers to complain that creativity on stage was a different thing entirely from creativity with a violin or clay.

Such decontextualization of imagination and creativity, and even self-expression in this manner, is a mark of Beardsley's transcendentalism. Theoretical work in contemporary aesthetics by such influential academics as Goodman (1976), Cavell (1988), Danto (1981), Davidson (2001) and Gadamer (1986) has not much filtered down into schools, but it raises the questions about the possibility of an aesthetic quality separate from its expressions in the arts world.

Most of these writers recognize the aesthetic as a human convention, even where it is tied to a nominalist realism. The arts become identified as a humanity, designed to make us aware of and sensitive to the varieties of human differences as expressed through the arts. Could "aesthetics" as a categorical term be replaced by the humanities? Aesthetics has recently benefited from "an ethical turn," a revival of long-standing debates about the moral function of narrative and the social impact of the arts, drawing aestheticians into the cultural value of arts education, but it is not clear how mutually inclusive this categorization could or should be.

Environmental issues could be said to be founded in an aesthetic notion of the essential beauty and sublimity of nature. The sciences too are recognized as human artifacts based on realism. What is it that makes an aesthetic experience in the arts differ from the one in logic or science? Some educators look to the arts because they offer opportunities to move beyond consolidated texts and change human values through revitalizing symbols and artistic rituals. Art is the lie that becomes the truth. Aesthetic education helps us to understand others as humans. What it is about this form of aesthetic experience that is unique to the arts remains to be examined continuously.

Aesthetics and Sport

Christopher Donald Cordner
University of Melbourne, Melbourne, Australia

Synonyms

[Drama, struggle and grace in sport; Meaning of sport for spectators, The; Sport's relation to beauty and art](#)

Introduction

People participate in sport, and also watch it. While they overlap, the attractions of playing sport are not the same as those of watching it. The field of aesthetics and sport is concerned with exploring and spelling out the kinds of interest and fulfillment sport can offer spectators. This article surveys the main themes of reflection on those issues in the last fifty years or so. During that time the focus of those reflections has changed. A tendency to separate off an interest in the competitive and ‘agonistic’ dimensions of sport from an interest in its ‘aesthetic’ dimensions of grace and beauty has given way to wider-ranging attention to ‘the whole experience of sport’ and its human meanings.

As well as benefits for participants, sport evidently provides entertainment and recreation to spectators. The field of aesthetics and sport reflects on whether sport can and does offer spectators more than is readily captured by those words “entertainment and recreation” and, if so, how that might best be described and understood.

Of course there is an important question about what benefits sports offer participants. That question has a long history. In addition to “the pleasure of physical and competitive activity,” one very common answer given to justify giving sports a prominent role in school curricula was that it was character building. Reflections on aesthetics and sport, however, focus mainly (though not exclusively) on the perspective of those witnessing sport rather than those playing it. The proliferation of spectator sports in the Western world from the second half of the nineteenth century is obviously an important factor in the growing interest in such reflections. For many decades, their main source was the writings of sports journalists. Philosophers and others outside the media entered the fray only from about the 1960s.

Aesthetics was long regarded as chiefly the study of beauty, whether beauty in nature or in works of art. When sport came into the purview of aesthetic reflection, two broad questions then became salient: whether the satisfaction of watching sports is helpfully explained in terms

of sport’s aesthetic value, understood broadly in terms of beauty, and whether sport is a form of art.

Heeding Friedrich Schiller’s description of grace as “the beauty of the freely moving figure,” it is evident that sporting performance can manifest grace and beauty. This might be the grace of specific movements – the running back’s fluid evasions, a downhill skier, Roger Federer’s backhand – or perhaps of a pattern of play, for example, a buildup of moves and passes in soccer or rugby. Much early discussion highlighted such aesthetic attractions of sport (Reid 1970; Vivas 1959, among many others). But it also seems clear that beauty and grace – even if we extend the range of aesthetic qualities beyond beauty/grace to include harmony, fluidity, balance, and elegance – far from exhaust what can compel and reward our attention to sport. Vivas speaks of watching a slow-motion film of ice hockey and focusing on “the beautiful rhythmic flow of the slow-moving men.” But that is no longer to see it *as* sport. What then is being left out in the appreciation of sport by a focus on its aesthetic attractions?

David Best (1974) undertook to locate sport’s aesthetic value in a wider context of spectator interest in sport by contrasting “aesthetic” and “purposive” sports. In purposive sports – for example, “football, climbing, athletics, orienteering, and squash” – what counts is the achievement of an end (“scoring a goal, climbing the Eiger”), and provided this is achieved within the rules, it doesn’t matter *how* it is done. Clumsy or fluky goals are still goals, and players would generally choose a clumsy goal over a graceful failure: “In sports such as these, the aesthetic aspect is subordinate to the main purpose.” In aesthetic sports, by contrast – for example, trampolining, gymnastics, figure skating, and diving – *how* one performs the relevant movements is not incidental but central: “doing it gracefully” is required for success, and the requirement is built into the judging of these sports. “Purposive” sports *can* be appreciated for their aesthetic qualities, but much of their interest for spectators lies elsewhere. This still of course leaves open the character of any further such interest. Is a spectator interest in victory, for example, an interest in sport *as sport*, or only in an

“external” feature, a consequence or outcome, of the sporting action itself?

In response to Best, Joseph Kupfer (1975) argued that “competition and the possibility for victory add to rather than detract from the aesthetic in sport.” Best and Kupfer thus seem agreed that much of the spectator value of sport cannot be captured in terms of its grace, beauty, harmony, fluidity, and elegance. But Best takes this to mean that such further value is not aesthetic, while Kupfer thinks the concept of the aesthetic is capacious enough to include these further values. Perhaps an ambiguity in the concept of the aesthetic generates some confusion here: on the one hand, “the aesthetic” is marked out by the supposedly “formal” qualities of beauty, grace, and harmony, and on the other hand, “the aesthetic” is whatever makes something (in this case sport) compelling or interesting to watch. The latter usage explains how the name of the field can still be “aesthetics and sport,” even given the recent dislodging of aesthetic value by some thinkers from the center of concern. The concept of the aesthetic needs further comment, but, first, Best’s discussion focuses another widely discussed question.

Is sport art? Best’s own version of the question is more restricted: can the aesthetic sports, undertaken with the aim of producing aesthetically pleasing movement, justifiably be considered art forms? Others though have argued more generally that sports are forms of art. Despite his more restricted question, Best’s answer to it provides a perfectly general reason that *no* sport, “aesthetic” or “purposive,” can be art. He holds that the possibility of “the artist’s comment, through his art, on life situations” is essential to an art form, while the sports performer “does not have the possibility of expressing through his particular medium his view of life situations.” Art has the capacity to be *about* war or love or suffering, while sport can only be *symptomatic* of cultural or social or moral or life issues. If the interest in the Louis versus Schmeling boxing bouts in the 1930s was a symptom of tensions between America and Nazi Germany, still the bouts themselves could not possibly be *about* those tensions. Best linked his distinction to the symbolic or representative

capacity of art. For instance, when Hamlet dies on stage, the actor playing him does not, but if the quarterback breaks his leg, then so does the man filling that position. Unlike actors, athletes appear and perform as themselves. Art’s symbolic capacity is what enables it to be “about” human life, as sport cannot.

Best’s distinction crystallized a fundamental issue. If sport is potentially meaningful in ways that exceed its capacity to offer entertainment and diversion (even if these things themselves need not be trivial), focus on sport’s grace and beauty is a first attempt to explain this further meaningfulness. When the attempt shows its limitations because it misses too much of what can compel our attention in sport, a natural next move is to suppose that other dimensions of sport’s meaningfulness owe to its sharing art’s capacity for meaning. Then whether sport really does offer something more than “mere” entertainment may seem to hang on whether sport is, or is not, an art. Playing some role in preoccupation with this question was also, perhaps, the assumption that the status of sport watching would be bumped up if sport could be given the imprimatur of art. One way of seeing developments in sport aesthetics in recent decades is as exploring a variety of ways of thinking about the meaning of sport that extend well beyond answering this specific question of whether sport is art.

One line of response to Best’s view undertakes in effect to identify things that sport is indeed “about” and so has the capacity to deepen and perhaps transform our understanding of, for example, the capacities and nature of the human body, the capacity for creative response to physical challenges (within the constitutive rules of a given sport), and the limits of effort and will in relation to chance in how things turn out. While this response has some force, it perhaps also seems rather limited in scope.

A second and somewhat different response allows that while there is something right about Best’s claim, its import may be limited because it risks over-intellectualizing art. Best himself admits that there are “difficult cases” for his view. It is hard to see how music or abstract

painting even allows for the *possibility* of “commenting on life issues.” But even with art that can and does offer such comment, its expressive power may very often not be a function of that “comment.” William Blake said that in Milton’s *Paradise Lost*, a poem intended to “justify the ways of God to man,” Milton was “of the devil’s party without knowing it.” Cordner (1988) therefore instead suggests that the deepest meaning and value works of art have for us may lie in the “life values” – including indefinitely many and complex modes of vitality, energy, and affective power – they manifest or express in and through their particular artistic medium. Lacking the capacity some (but not all) artworks have to “comment on” life issues, sports too may exemplify in their own bordered domains an indefinitely wide range of such life values.

A kindred theme is found in Andrew Edgar’s view (2013) that “sport is expressive of a world,” as art is. The “world” that a work of art is expressive of need not be most importantly shaped by the intentional or self-conscious comments of the artist. The world-expressive vitality of art is shaped by the total activity of the artist in his/her artistic “medium” – and the artist’s “comments” on life issues are but one aspect of that. Analogously, the world-expressive vitality of sport is shaped by the total activity of sports participants in *their* medium.

These alternatives to Best’s distinction suggest that the question of the identity or nonidentity of sport and art has moved from the center of discussion. Even deep connections between what art and sport have to offer the spectator need not be thought to depend on sport *being* art. More interesting and revealing is a sustained working out of similarities and differences.

Another recent theme of sport aesthetics is crystallized in Edgar’s claim (2013) that “discussion of sport in terms of its beauty tends to conceal more profound and disturbing questions as to sport’s meaning.” A focus on “traditional” aesthetic values of beauty, grace, and harmony distracts from what a “modernist aesthetic” can appreciate: the *agonistic* dimension of sport – the qualities given rise to by its elements of struggle

and striving. As examples of such qualities, Paul Davis (2015) mentions doggedness, tenacity, resourcefulness, faith, command, plenitude, repose, urgency, patience, and dignity. And he highlights some related “defining qualities of (the world of) sport, e.g., visible toil and strain, the intrinsic possibility of failure, the visibly strenuous working with materials (most obviously the body), one’s exposed vulnerability to conditions, luck, loss of form, and the injured or aging body,” crystallizing this as “the visible realization of life values (only one at most of which is beauty) in a self-enclosed domain.”

This emphasis by Edgar and Davis presses further Kupfer’s much earlier (1975) resistance to a preoccupation with beauty and harmony: “some games are tense, stingy encounters in which defense dominates and scores are hard-earned as if squeezed from a resistant world.” But where Kupfer still confined his picture within a frame of “inclusive rhythms, denouements, consummations... wholeness and finality,” Edgar and Davis open their picture up to the compelling character of the disruptive, the fragmentary, and the dithyrambic in sport. Edgar sees this bringing of sport under a modernist aesthetic as thereby linking sport’s spectator value to the affirmation and renewal of everyday life, a link he thinks is broken by a focus on sport’s “traditional” aesthetic value.

Lev Kreft’s (2012) locating of sport aesthetics under the concept of the *dramatic* advances a related line of thought. He speaks of sport as performance which, while it is “under suspension of everyday reality,” yet retains a more intimate connection with everyday life than art does. Kreft “brackets” sport, but brackets it *within* the everyday rather than *from* it, and so in a way that distinguishes sport from art in several related ways already touched on. Unlike actors in a role in the theater, athletes and sports people perform “as themselves” and so are themselves humanly present and vulnerable in what they do. Partly for that reason and partly also because sport is (again unlike theater) unscripted, as real people performing in real time, sports performers are exposed to an ever-present risk of failure in their

activity. Awareness of this vulnerability and exposure is then also a crucial element of spectator experience of sport. So is their uncertainty about the outcome: what will happen is not just unknown (as the outcome of a film or play seen for the first time may be unknown). It is also undetermined, to be actually created by these participants, and witnessed and commonly affirmed by those watching. These differences do not make sport either “better” or “less good” than art (even though Kreft himself suggests “real” sport drama is more compelling than “representational” theater). But the differences do help shape the distinctive character and possibilities of sporting drama. The “staging” of sport that gives it a distinctive space within the everyday – sports arenas and courts and stadiums – plays its role here too: any “failure,” for example, is (or should be) held within that frame, whether it is just a loss by a team that has given its all or instead a failure of nerve or of courage or of stamina, by individuals or most of a team. These are indeed *real* failures of nerve, stamina, and courage, but not all of their everyday implications are in play.

A shared theme of these (but also of some other) recent developments is the centrality of the human body to the dramatic significance of sports. Stephen Mumford (2011) says that “Sport shows us the excellences of embodied agency” – and not only the excellences of it but also, and poignantly, its limitations and vulnerabilities in the face of many challenges and strains. (This explains, in passing, why chess and scrabble are games but not sports – the excellences and vulnerabilities of the players’ embodied agency are not intrinsic to the drama of these activities.) While these excellences and vulnerabilities *can* be expressed in all sorts of other activities too – in war, perhaps, or in the performance of intricate surgery or of chopping wood, in peeling potatoes, or in rescuing a cat from a tree – in sport the activity is bracketed from the everyday purposes served by our embodied agency. Sport’s very “pointlessness” invites us just to attend wholeheartedly and whole-mindedly to the display itself.

What Edgar calls the meanings of sport, Kreft its distinctive dramatic mode, and Cordner and Davis its realization of life values can be seen as differing but related formulations of a common theme. In none of these formulations is the concept of the aesthetic salient. Indeed Edgar holds that a traditional preoccupation with the aesthetic has distracted from appreciation of the import of sport’s agonistic dimensions, for him the most important site of sport’s meaning: “while something that is beautiful has thereby intrinsic aesthetic value, it nonetheless lacks relevance to everyday life.” Edgar therefore urges a shift from an aesthetics to a hermeneutics of sport – as part of an attempt to bring out the full human range of sport’s implicit meanings. This reorientation is finding wider favor in the field. Cordner (2003) sounds one note of caution. Edgar expresses some plausible skepticism about a widespread admiration for beauty in gymnastic performance: there is perhaps less grace in the classical gymnast’s dazzling set piece than in some footballer’s marvelous intuitive negotiation of heavy defense, for example, or maybe even in her single momentary pivot. Cordner argues that the meaning of graceful movement lies in its affirming for us the possibility of finding ourselves “at home” in an uncontrollable and recalcitrant world. The wonder of the footballing moment is then this glimpse of harmony marvelously wrought from an erratic contingency of forces ever threatening our embodied agency. This is no reversion to a grace hermetically sealed from the agonistic struggle in a domain “lacking relevance to the everyday.” As enacting a transformative self-presencing out of the world’s chaotic energies, such grace is *already* the site of experienced meaning, intelligible only in intimate relation to both sport’s and life’s agon. If past discussion of aesthetics in sport has often reflected a devitalized conception of beauty, that was perhaps a limitation of the discussion rather than of beauty or grace itself.

The field of aesthetics and sport has continued to become richer. One effect of the ways it has become so is that the two questions arguably framing the field in its early days – “is the

satisfaction of watching sports best explained in terms of sport's aesthetic value," and "is sport art?" – have been not sidestepped but transcended. Better and richer ways have been found of engaging with concerns that can be seen to underlie and to have motivated those questions. Increasingly, those working in the field of aesthetics and sport have reached for, and uncovered elements of, "a language that embraces the whole experience of sport" (Edgar 2013). The exploration will undoubtedly continue to range further.

Introduction

The terminology *ako* means, in Māori language and culture, to learn, teach, advise, study, and instruct. The word and meaning are shared with the languages of Tonga, Samoa, Niue, Tokelau, and the Cook Islands, among other groups of people from the island homelands (meaning South Pacific region). Principally, unlike the dominating English-speaking New Zealand Pākehā European culture, no distinction is made between learning and teaching. On this principle and in response to the problem of indigenous Māori people, in educational institutions, such as the university, passively receiving useless information to do things for the prevailing culture, a deeper philosophy and a broader theory of education will be considered in this chapter. Through teaching and learning as a whole and not as unrelated parts, people's feeling about life, of gaining experience, and our senses cooperate, and through the cooperation of senses, experience, and the body with spirits, a Māori point of view will make a practical philosophy of dialogue without end, mutual learning, and mutual enhancement.

Ako, A Māori Point of View

In Aotearoa, writers, scholars, educators, teachers, students, and parents have become used to the recorded melody, the picture, and the short-lived exploit perpetuated in multimedia and projected globally. We are less accustomed, though, to understand an ancient culture of communal ways of living like that of Māori society where wisdom or the highest form of thinking was almost exclusively oral. Significantly, the ritual and shared exchange of words, in speechmaking and song,

no less than the exchange of commodities, services, and women, upheld communication between tribes and sustained social coherence in the culture (Mitcalfe 1974).

Cowan writing in the 1930s hailed Māori as a group of people with an “original sense of artistic values in decoration and craftsmanship . . . a people of keen intellect . . . the creative faculty very highly developed . . . vast stores of folk lore and poetry accumulated in the course of untold centuries, and handed down one generation to another” (Cowan 1930, p. vii). He advised further that in spite of this beautiful tradition, Māori wisdom was passed onto others through New Zealand Pākehā European interpretive writers, rather than the Māori artists, craftsmen, and composers. Consequently, over generations, this act of oppression has separated Māori from the wisdom, beauty, and satisfaction of their culture.

To the north of Aotearoa, Beaglehole writing, in the 1940s, about Tongan people, elaborated that the most important thing wrong with the relationship between European and Tongan society was that the educational process is an effective instrument for separating the people from the satisfaction of Tongan culture and, equally, from the satisfaction of the European culture (Beaglehole and Beaglehole 1941). Similarly, Jean-Paul Sartre has conveyed to the world that “[v]iolence in the colonies does not only have for its aim the keeping of these enslaved men at arm's length; it seeks to dehumanize them. Everything will be done to wipe out their traditions, to substitute our language for theirs and to destroy their culture without giving them ours” (cited in Fanon 1990, p. 13). The danger is clear. There is a culture where part of the world lives their life doing things and part of the world makes others do things for them or, even worse, makes the world impossible for others to do anything for themselves (Yutang 1996).

Alexander writing, in the 1970s, articulated that people, who become whole, proclaim their views of the world, loud and clear for everyone to know, are not dissatisfied, not afraid to stand up for their values and place, to recognize their shortcomings, trying to change them, and still be proud and glad to be themselves. He expressed that

people, and their beautiful language and culture, customs, and values, can coexist with others with whom they share the world. Accordingly, on thinking *ako* in the South Pacific, from a Māori point of view, the problem to be worked out between two cultures, this ancient Māori philosophy of the body with spirits, and the domineering civilization of material prosperity are how should Māori organize our life so that we expect new answers to the problem of teaching that is separate from learning or what are better new methods of approach that are intellectual, complicated, heartfelt, and satisfying, through which Māori are awake to the world or, still better, a communal, oral philosophy to connect with an individualistic, written theory.

Of course, not all of the ancient Māori philosophy of the body with spirits, collectivity, oracy, judgment, and satisfaction will coexist with the technological civilization and vice versa because their surroundings, settings, and locations contain points of reference that are mutually alien. Furthermore, people who migrate, from, say, the Kingdom of Tonga to Aotearoa, may well elaborate the Māori philosophy, and, together, they may elaborate the technological, measured, uniform, passive cramming of useless information for profit (Yutang 1996). On balance, there is sufficient similarity in people's feeling and forms of expression to enable the coexistence of a communal, oral philosophy to an individualistic, written theory, without losing the original ideal of learning and teaching as coexisting (Manu'atu et al. 2014; Yutang 1996; Mitcalfe 1974).

For the moment, the dangerous issue for Māori colonized to the ideologies of global consumerism and capitalism is that education connected to material prosperity is of a magnitude transcending the spiritual vivacity of their daily living. However, the people's explication of the relationship is not to extinguish the greater strength of material prosperity; the notion of elimination is both fanciful and cruel. They should not do away with the aspiration, imposed or not, to accumulate material wealth; the idea has been so well established and is so compelling that eliminating their hope for material wealth is both capricious and malicious. The accumulation of wealth is not the issue of

importance. The worry is when Māori prosper materially beyond their spiritual wisdom to learn and live in peace and harmony (Manu'atu et al. 2014).

In the South Pacific region, many groups of people share a similar struggle to coexist with the prevailing machine society; therefore, any thinking on *ako* must start out with understanding the beauty of the pagan world, a strong feeling of the limitations of life, and a sense of dignity. In reality, ancestors of Māori were philosophers, and they thought deeply about the coexistence of the body with spirits. In the present day, Māori people would have heard the ancient story of Rātā that expresses the sacred relationship between gods and people.

Rātā, a young man, went to the forest to decide on a tree with which to build a canoe that would carry enough men to punish those who had killed his father. The young man selected a large tree and for the rest of the day he felled and trimmed. The next morning, he returned to commence making the hull of the canoe from the tree, only to become aware that the log was once again a living tree. There was no sign of the tree that he felled the previous day! Rātā, perplexed, nevertheless, selected a new tree and set to felling and trimming again. The following morning he found that the tree had been restored to life. After a third felling, Rātā hid close by, hoping to catch the culprits in the night. As the sun set, the forest came alive with the "hordes of Hakuturi, the tribes of little people" (Mitcalfe 1974, p. 22). They were heard by Rātā to chant a *karakia*, an incantation to restore life to the tree. From the Hakuturi, Rātā learned the proper ritual of appeal to Tāne, the god of the forest, for felling trees. The spirits taught him, too, that people are no match for Tāne and that they are not the masters over gods.

Karakia are the body with spirits of Māori culture; the incantations are the source of imagery, enriching the more humdrum forms of language from oratory to songs and to poetry. In their ceremonial settings, exemplified by baptismal rites of newborn children of high-ranking parents and the ritual chants of welcome and death, *karakia* interpose between the people and the gods; the sacred chants stand beyond yet within the communal

consciousness, similar to the way the subconscious serves to the conscious mind, storing and replenishing wisdom (Mitalfe 1974). The ritual chants are the way with which Māori come to grips with the impact of spiritual forces on material substance and vice versa. Karakia that accompany actions of offerings to the god of the forest, and so forth, have been passed down through Māori Antiquity, and the word is the main medium to symbolize and express tribes' relationships, not only with the spirits but also with each other and death.

Concomitantly, the story of the Israelites entering the Promised Land, in the *Book of Joshua* in the Holy Bible, has resonance for this Māori point of view of ako, in the South Pacific. Like the Israelites, Māori and migrants such as from the Kingdom of Tonga to Aotearoa have had to live and remain living underprivileged lives. Through the European culture, Māori have learned to accept that the Christian God is omnipresent and to believe that they, too, are that God's chosen people and that this God demands that they should be virtuous, moral people. For them, too, there is the experience of "crossing the Jordon" in their migration, over generations, from the tribal lands across rural Aotearoa, and the Kingdom, to the market gardens, factories, and ghettos of urban New Zealand. They live by faith and trust in this God just as the Israelites do. The narration is plain. In the South Pacific, a philosophy of the body with spirits is at home with material prosperity.

Ambitiously, ako is the principle through which to share the good in the bad and bad in the good to make a philosophy of spiritual and material prosperity. As mentioned previously, Māori shares the principal of teaching and learning without distinction between the two actions with the people of Tonga, among others. The point is that together, their words and wisdoms may well elaborate a practical philosophy. While Māori culture was produced in Aotearoa and most of what Māori believed about their changed circumstances was indigenous wisdom formed in Aotearoa, their language had no contact with other languages because these tangata whenua, the first people, remained isolated from their island homeland in the Pacific Ocean, for

centuries. The matter of importance is not the geographical distance, rather the idea that Māori and Tongans share a common linguistic ancestor, that is, their languages belong to the same subgroup of Austronesian: Polynesian. The traditional stories that Māori brought with them are the same as those told in Tonga. The idea that language changes is neither particularly remarkable nor useful to this discussion (Kēpa 2008). The satisfaction lies in the notion that ako is an ubiquitous, linguistic influence in the South Pacific.

In this philosophy of the body with spirits, consider, too, the Tongan word taulangi that refers to "reaching for the sky." Principally, the ideal will enable new approaches that coalesce around a dialogue without end to convey spiritual and material prosperity, rather than education as assimilation, colonization, and genocide. While the principal is concerned with Tongan wisdom, this spirit of passion and approach to spiritual and material prosperity is familiar to Māori. The important change is that Māori and Tongans will no longer only be instructed for manual labor in New Zealand society; rather, they will learn about spiritual and material prosperity, citizenship and wisdom, education and work, and discrimination and the economy.

In 2013, Auckland University of Technology's School of Education Te Kura Mātauranga commenced teaching the Bachelor of Pasifika Education Early Childhood Teaching (BPasifikaEdECT) (Kēpa and Manu'atu 2012). The qualification called for Tongan, Māori, Samoan, Cook Islands Māori, and Niue educationalists, among others, who are passionate enough to make a change of approach in education, knowing full well that whatever is made may be disliked by their colleagues and countrymen and rejected by politicians and administrators who organize New Zealand society. They had to be firm in their spirit to make a change in the school's individualistic curriculum and pedagogy, to resolve debates themselves, without calling on outside authority. They had to show fortitude and good sense and to proceed with these principles, rather than to react to the dominant culture mechanically and uniformly. Passion is the close

companion of creative education. For unless people in education are passionate, there is nothing to start out change of the individualistic, written theory at all. In truth, passion is the spirit of success, light in education, judgment in the economy, beauty in work, satisfaction in citizenship, and happiness in wisdom. The promise is mutual learning and enhancement.

Continuing in the spirit of hope, this approach to learning and teaching, led by Tongan and Māori educationalists, among others from the South Pacific, will shake the education culture in Aotearoa. They will articulate the spiritual and material forces that will decide the organization of the people at different times and places, thereby clarifying the changing relationships between them, the State, and education in a neoliberal era. Critically, changes will be questioned through drawing on the rise and fall of those ideas by which they are trained for manual labor in the dominant education culture, and the new philosophy will coalesce around taulangi, creative education.

Similarly, the term *ngā pae o te māramatanga* that refers, in Māori society, to many horizons of insights of wisdom is an ambitious approach to end the separation of teaching and learning (Kēpa and Manu'atu 2012). The approach is imbued in the body with spirits from the South Pacific. In fact, *Ngā Pae o te Māramatanga* (NPM) is a Centre of Research Excellence (CoRE) funded by the Tertiary Education Commission (TEC) and hosted by the University of Auckland. NPM is an important agency by which Māori society is becoming a key player in international indigenous research and affairs. Once again, the spirit is to draw on the creative faculty and ancient wisdom of Māori and to bring about change for the better, for all people, in Aotearoa, New Zealand. The CoRE is the funder of the International Indigenous Writing Retreat held twice a year in an isolated coastal village in northern New Zealand.

The writers who withdraw from the mundane world could suppose that attending the retreat is a condition demonstrating the value an employer has for an employee and vice versa. The analogy with equity or fairness elaborates on the purpose of participating in the sanctuary which is to retreat

from the invasive computerized workplace; to commit to the academic responsibility to write; to ponder on language that is full of ambiguities; to portray thoughts that are intellectual, complicated, and creative; to enjoy the freedom to debate with no sense of loss of approval, blame, and satisfaction; to confront the intellectual impoverishment of the computerized workplace; and to come to grips with issues and conditions beyond the experience of the individual. Purposively, the retreat is to support the well-being of the writers and so to support the transformation of societies and economies for the material and spiritual prosperity of their people. The purpose of education for coexistence is the light.

The program has been established for writers from the colonies to retreat from their dominant society to dialogue together. For 16 retreats writers have arrived from universities across New Zealand, Tonga, the USA, Canada, Nepal, India, Mongolia, and China. These writers come from the disciplines of education, Māori studies, indigenous studies, anthropology, psychology, sociology, public health, medicine, and so forth; they bring collective values on words and wisdoms to scholarship and dialogue. The retreat is not a *laissez-faire* gathering of preoccupied intellectuals, nor a purely egalitarian or communist state of affairs. During the day, the writers are engaged in contemplating and writing scholarly articles, chapters in books, books, submissions, research proposals, essays, reviews, technical reports, and cultural reports; discussing areas of shared research interest with one and two new colleagues; and sharing texts and ideas in a particular research area with colleagues. The retreat most closely resembles a sanctuary wherein the writers are hopeful in sharing suffering, loss, inspiration, aspiration, and satisfaction and in imagining education committed to spiritual prosperity and material prosperity. These words are the ethical principles that distinguish ako.

Ultimately, from a Māori point of view, ako is the genius handed down from one generation to another. Ako is a dialogue without end through which the people share their thinking and make a philosophy of education that is mutually creative, curious, and dignified.

Alchemy of Love an Artist Praxis to Autonomy and Political Visibility

Sylvia Richardson
Arts Education, Simon Fraser University,
Burnaby, BC, Canada

Synonyms

Love; Reciprocity; Somatic knowing and intentional co-creation

Introduction

Either the world is so tiny or we are so enormous; in either case we fill it completely. . . . (Kafka, cited in Buber-Neumann 1989/1988, p. 56)

Love is an alchemic process that expands and evolves our wisdom through a mastery of awareness, attention, and intention that is single-minded in focus. I believe it is impossible to be in love and be in fear at the same time. Love opens our Imagination, is a gate to possibilities; what we believe is possible, we can create. All stories reflect the storyteller and where they are in their lives.

The truth is not in the story. The truth is in the power that creates the story. . . . When the voice of knowledge becomes the voice of integrity, you return to the truth, you return to love. (Ruiz 2004, p. 228)

What is love? “Love is a quest for truth” (Badiou and Truong 2012, p. 22); it forms and informs my epistemology, ontology, axiology and methodology of how I come to know my world(s). “Every head is a world. . . Your world is your creation, and it’s a masterpiece of art” (Ruiz 2004, p. 51). The multiple worlds we create: political, economic, cultural. . . reveal the affect of individual and collective imagination. An intentional path to being in resonance with a living world inspires a call to be attentive, a deep listening.

Stories are co-created in relational reciprocity – co-author – by the writer and the reader. We are defined by our stories of love, death, and rebirth. In the sharing of my stories I “witness a part of myself, the part that views the world as miraculous that is surprised at the chance of existence. . . , continually moving outward, gathering knowledge, and skills” (Leavy 2015, p. 110), a reflexive process of learning and experience. . . then returning inwardly to love (truth). Listening for, the titbits of knowing revealed in the daily rituals we adapt to, reject and or invite.

Remembering what we have forgotten we forgot.

LOVE Is the Golden Key to My Deserted Castle

My heart holds secret fires, sparked by a lover’s time-stopping gaze penetrating and revealing of my soul. The sensuousness of my lover’s voice across a crowded room; the tingling of skin provoked by a gentle kiss. The rupture that lingers after orgasm, amidst creased sheets, a private secret

...at last is out. In the twilight, eyes reveal not so much the past, as the future struggle ...the fear of the end. Is this love? In surrender to the impulse, the cobwebs from the mirror are removed, and my secrets revealed. The truth that lies within. . .

“Love is a quest for truth” what kind of truth? “truth in relation to something quite precise: what kind of world does one see when one experiences from the point of view of two and not one? What is the world like when it is experienced, developed and lived from the point of view of difference and not identity? That is what I believe love to be.” (Badiou 2012, p. 22)

We lived within multiple worlds, the world that plays out in our head – in memory or imagination, in speculation or interpretation – the worlds we imagine and worked to create. The heart is a marvellous muscle of memory and strength. A faithful guardian of the spirit (soul), courage is cultivated in adversity. My fear and courage are tested in those magical moments of coincidence, in the serendipitous encounters that birth new awareness.

Born to a world filled with violence, fear would not let me stand still... fearful of the unknown. I was a wanderer, clutching to my need for certainty in a world of uncertainty. I tried to convince myself that “life is what we make of it” and immersed myself in the daily rituals of subsisting, adapted to the busyness of doing, to the habit of getting by. And without warning I have become lost in the non-stop emergencies that plague the chronically poor.

To live with an open heart means that pain is no stranger, but wonder will be a constant companion. David Oldfield (cited in Badonsky 2007, p. 9)

I loved with fearful confidence that whatever the consequences love was worth the risks. There is never smoke without a fire. . . Love is the alchemy that births us into being in awareness of each other, of ourselves, of our surroundings, into awareness of this perfect. . .temporal and fragile life.

Death. . . Do I dare love life, knowing life will end?

Death

It was a perfect night to die.

The air was moist and humid inside the apartment, though the temperature outside was a comfortable 22° Celsius, the heat from the oven where

his prized Sockeye stakes bake with a light batter of dill and mayonnaise (his secret recipe) had created a savannah like environment.

“Dinner is ready” his eyes anxiously awaiting my response to the first bite. “Yum!” exclaimed our daughter capturing his attention; her brother joined the chorus of praise that ensued. He waited with an anticipating smile as I exclaimed, “Honey, this is delicious!” Love is revealed in moments, simple acts of kindness, of appreciation. . . his face was luminous with love.

Love! Not just some passing moment a glance however open but some deeper compassion radiating permanency. (Vanier 1970, p. 38)

In the kitchen a mountain of cut fries remained.

After dinner, still in disbelief of his achievement, praise for his accomplishment continue. . . “Daddy you are a good cooker” said our son with a smile. We snuggled in front of the TV. . . “Did you turn off the fire daddy?” asked our precocious 6 year old to which he replied “I am still cooking”. . . “Why” she insisted, “we don’t waste food” he said firmly, and she smiled approvingly. . .

On this summer night, with bellies full, the heat of our bodies squeezed into the sofa bed, lulled by the nice breeze, scented air, and music played softly in the kitchen, sleep crept upon us all.

Feeling thirsty, I wandered into the kitchen half asleep,
“FIRE” . . . “FIRE” . . .
What lies deeper than the moment? . . .

Standing inside the shipwrecks, inside the chaos, the golden key. . . stillness, a single-minded focus. I see myself at last, “How naturally what’s needed comes from you, always.”

I remembered the fire extinguisher we had bought only a month earlier at a garage sale. . . “it’s brand new” the woman who sold it to us said smiling. She neglected to mention it needed to be pressurized for it to work. And we did not read the fine print.

The world have us pre-gown. . . life as a continuous running and never arriving. . . missing the writing (the fine print of life) I had adapted to a self-flagellating story marking stones in my reverence of being good. Freedom had eluded me in a state of non-stop emergencies. . .

Feeding myself a daily diet of shame and guilt, of “not having done enough” . . . , running to do more. . . .

Poor people make an art of living, being alive in the moment was an artistic, existential and political act. “In politics, events are ordered by history in retrospect. But art is alone in restoring or attempting to restore completely their intense power. Only art restores the dimension of the senses to an encounter.” (Badiou and Truong 2012, p. 78).

There is always another story, beyond what meets the eyes. . . a breath, divided this gulf of life and death.

Love is an art of obstinacy, the miracle that brought us together, that scripted our lives into this particular family, and in this particular moment. Love, revealing and advancing a higher understanding of who am I, of who we are. . . what is worth saving of myself?

What is worth dying for?

“FIRE. . . .”

How can one word, inspire so much terror?

The smoke made it impossible to see 2 ft in front.

“GET OUT” he yells, our daughter was first to wake up as he picked up both children in his arms and began running towards the door. Her kindergarten teacher had conducted a fire drill only a week earlier and she seemed ready for this. . . . “CRAWL DADDY SMOKE RISES” she tells him in a matter of fact way, with intermittent coughing. He ignored her requests but she persisted “CRAWL DADDY, SMOKE RISES” as he made it out of the building with both children in his arms.

“Why is the fire alarm not working?” without notice my partner returns to the building to knock on every one of the 12 units in the 3-level walk-up apartment building. A neighbour across the street had called the fire department on his cell phone. A crowd now gathered on the street.

The Fire Fighters truck’s sirens and ambulance lights were calming to my fears.

The fire trucks arrived shortly after. It only took minutes to extinguish the fire; but the apartment and everything in it was destroyed. “The fire is out, all of you but the family where the fire

originated may return to your home” approaching us the chief said gently “The fire alarm in your building had been shut off, you are very lucky to be alive.”

No one spoke. . . .

Inside the ambulance, the oxygen masks, distorted the faces and cloaked in silence. The scene was surreal; a caricature of our family, about to be devoured by the monster, FEAR. The uncertainty of the unknown silenced the screams that would be hysterical but for the disbelief of what had just happened.

A stranger’s voice interrupted the silence. “I need to know who was exposed to the smoke the longest” said the ambulance attendant. “It was me. . . .” said my partner removing his oxygen mask “I went back to knock on my neighbors’ doors. . . .” I looked up lovingly and filled with pride, acknowledging the risks he had taken.

The ambulance attendant seemed unmoved by his heroics.

Pulling a syringe from his first aid kit, he approached him and reaching towards his arm said, “I will need a blood sample from you then. . . to check for carbon monoxide in your blood.” Afraid of needles since childhood (a secret he would rather keep to himself) his pupils grew wide but his usual wit returned with lighting speed “actually it was my son. . . .” pointing to our 5 year old being cuddle in my arms.

We burst out laughing aware of his mischief. “I guess you won’t be cooking again, hah daddy” our daughter interceded looking at him with a sweet smile and everyone joined in the laughter that was now contagious. Beneath the thorn of disappointment, a wide-awake, exhilarated, and heart-pumping feeling of sensuous awareness (as when you are in love) consumed me.

We spent the night at the hospital.

Rebirth

. . . In the morning light, the apartment seemed magical.

I remember covering the walls of our apartment with royal blue, paisley patterned wallpaper

(purchased at 80% discount) “the discolored patches add an aesthetic quality to the pattern.” I insisted trying to convince him that our purchase (which was not refundable) had been wise, “it’s beautiful” and “authentic” . . . I insisted as I tackled hand-made curtains to the wall.

Accustomed to life’s imperfections (inequality) and coincidences of fate (injustice), the ironies became epiphanies to my willing youthful heart. What is a home? . . . a sanctuary of unanswered prayers for the marginally employed (chronically poor), a co-creative hub where bill payment strategies were achieved through intentional ingenuity of living.

A home is filled with symbols that defining a shared space, the ordinary objects imbued with the essence of life in this particular family, our particular story. Even the patchy papered walls had been imperfectly beautiful. . .

A home is filled with heart secrets; the walls were faithful confidants embracing the laughter, tears, dreams, and longings shared out loud, the sounds of awe and wonder in conversations shared, and now imprinted in their smoke scented planes.

Love is revealed in daily rituals of living. . . designed by necessity and ingenuity. The deepest desire we share is that of connection, free to be fully ourselves, to risk and create. . . revealing ourselves in our stories.

“Are we poor?” our daughter asked one day as we walk home from school fixing her brown eyes upon my partner’s blue eyes, the way she looked at him when she wanted a straight answer.

He felt his heart leap to an accelerated rhythm, moved by her intensity.

Then, as if prepared for this inevitable moment he replied:

“Not at all! . . . We are Hundredners!”

and opening his wallet he produced two banking cards. . .

“look we even have two bank accounts” (he neglected to tell her, both accounts were overdrawn).

She smiled and happily skipped the rest of the way home.

He winks at me and approaches my ear as if to plant a soft kiss, then whispers. . .

“We won’t always be so poor.”

The daily habits of getting by, loving, sharing our lives, making a sacred ceremony of life itself, celebrating our infinite subjectivities, carrying the sun in a golden cup, singing, dancing. . . Inventing worlds, and words to describe our world.

Co-creating abundance by embracing simplicity of life, the lightness that comes from having few things, creating a habit of defining needs as wants and declaring them “non-essential”. Looking for the magic of life, in the daily nuanced ways of mitigating the fear of hunger, homelessness, marginal employment, and poverty enduring wages, in a wealthy nation.

We choose connection with our world when we choose the ability to respond and take action. True freedom is the ability to choose one response over another. The beauty of life experiences is that while we cannot undo what is done, we can succeed it, understanding it, learn from it, and change, so that every new moment is spent not in regret, guilt, fear, or anger but in wisdom. Standing at the cross roads of doubt (fear) or courage to surrender. Lived experience had taught me I can choose to stay prisoner of my regrets and sadness, re-living each painful detail of the fall, which only brings more suffering. . . immersed in the waters of my failed expectations.

A life is made up of promises, of dreams, and of longings and memory. The ontological beingness of my soul is my physical body; these memories captured in photographs, the objects I surround myself with allow the world to see into me, to know me.

A campfire scent permeated the air. . . announcing the death of simple things. Love is a spiritual awakening, when we love we pour ourselves over the object of our affection like water on parched earth, a freedom envelopes the lover with limitless resources and resourcefulness and no fear of running out. In love, we become the reservoir of love. . . “Love is an essential project: to construct a world from a decentred point of view other than that of my mere impulse to survive or re-affirm my own identity” (Badiou and Truong 2012, p. 25).

Amidst the ashes, we found rebirth.

In the ashes of what was, lovers risks creating again. . .

LOVE's Alchemy is LIFE

Art reduced to its simplest expression, namely, love.
 Andre Breton, (cited in Badiou 2012, p. 80)

Time takes shelter in a silent obscurity, without roadmaps we are free to wonder new worlds and when old words die out, and familiar paths are lost, new ones are revealed to the open hearted. Becoming present to our rituals of relating to ourselves, to other peoples, and to our surroundings. Love invites a new script of living that disrupt individualistic competition and power with an embodied, relational, and located subjectivity that is interdependent.

To hope is to risk despair.
 To try is to risk failure...
 The greatest hazard in life is to risk nothing.
 Only a person who risks is free.
 (Author unknown, quoted from *"The Psychology of Courage"* 2010, p. 112)

Love's nuance affect, confronting tropes of authority with a collaborative ethos of decentralized power, committed to open spaces for those silenced (by economic, political, and social exclusion...). Connection is our deepest desire and need for survival.

Love is always the possibility of being present at the birth of the world. (Badiou and Truong 2012 p. 26)

Love stories, written in moments of embodied symbolism that birth new categories: woman, mother, journalist, artist, ... each locating and displacing within geographies of power, revealing the multiple layers of objectification that must be overcome on the path to liberation from a colonial, anthropocentric, market-oriented world, mechanized way of seeing without presence.

The path of least resistance and least trouble is a mental rut already made. It requires troublesome work to undertake the alteration of old beliefs (Dewey 1966/1963).

We create the world each day, with each action we take or fail to take. The journey of self-awareness is never ending. In the fire, there is life. I am the artist of my life, as I grow in awareness of my own inner wisdom and surrender to my heart's sensuous calling: to love with earnestness and

strength. . . inviting joy, playfulness, curiosity, and wonder to each moment. Being open hearted is to be willing to risk, to embrace the unknown, and see possibilities where others see dead ends.

Artists make a small thing big, allowing expansion from the inside out. . .tapping into experiential wisdom attempting to include the nuanced beauty, love, and hardship of life into a canvas, a poem. . .a story. Weaving the Ontology, epistemology, methodology, axiology into an interdependent circular process, forming and informing each step; shaping a praxis of autonomy and political visibility. Revealing ourselves in our process of knowing and how we come to know what we know. Rather than compartmentalize each, research can be embrace as a "Ceremony of Relationality" (Wilson 2008 p. 70).

Our stories make visible the worlds we live in and within; narrative represents, constitutes, and shapes social reality (Bruner 1987, 1990, 1991), as authors of our stories we come to know ourselves and create meaning of the world (Bruner 1990). Story telling is a way of knowing, revealing "reality and knowledge as socially constructed" (Etherington 2010, p. 75), exposing the positionality of power and knowledge as situated within contexts and embedded within historical, cultural stories, beliefs, and practices.

To love is to be willing to die to our old habits of thinking and risk being in awareness of the our feelings, surrendering our private fear of failure with compassion and courage to start again. . .honouring the courage and love of self and others we are manifesting every time we get up from a fall.

Everything is relationships. The ontology (what is real) and epistemology (beliefs systems of how we come to know what we know) are grounded upon a process of relationships that form a mutual reality, each informing and forming the other. The axiology and methodology are grounded upon maintaining responsibility (ethical accountability) to these relationships.

What is truth is real.
 Love is real.

It is the supreme expression of life. Don Miguel Ruiz, a Toltec Wisdom Book "The Voice of Knowledge".

► Phenomenology of Higher Education

Allegedly Conservative: Revisiting Wittgenstein's Legacy for Philosophy of Education

Paul Smeyers
Ghent University, Ghent, Belgium
KU Leuven, Leuven, Belgium
Stellenbosch University, Stellenbosch,
South Africa

Synonyms

Conservative; Epistemology; Practice; Practitioner; Researcher; Wittgensteinian legacy

In section 124 of the *Philosophical Investigations*, Wittgenstein writes: "Philosophy may in no way interfere with the actual use of language; it can in the end only describe it. For it cannot give it any foundation either. It leaves everything as it is." Given the unity of language-and-world and of what-we-say-and-do at the level of the language-game, it is easy to see how it gave occasion to the reproach of conservatism – particularly in education and philosophy of education where the rhetoric of change has always been fashionable. Philosophy is all caught up with how we think about ourselves; thinking and reflection belong to our life. Thus our life is at least *partly* correctly characterized as permeated by thinking and hence changed by thinking. How can coming to understand something *not* make a difference? According to *The New Oxford Dictionary of English*, as an adjective "conservative" means "averse to change or innovation and holding to traditional attitudes and values, typically in relation to politics or religion" and as a noun "a person who is averse to change and holds to traditional values and attitudes, typically in relation to politics" (1998, p. 391). It is doubtful that in any of these senses Wittgenstein's philosophical work is conservative. Such a justification could not be offered according to Wittgenstein's own profoundly anti-foundational stance (see further). His remark is part of his more general hostility toward "the craving for generality." This distaste for theories and explanation seems to put not only philosophy but also any social science under pressure (i.e., an eternal paralysis as far as action is concerned). So again one is pressed with the issue what Wittgenstein could have meant.

Taking # 124 out of context implies the impotence of philosophy; instead, let us consider that Wittgenstein's point had to do with language alone. Wittgenstein does not say that everything in our understanding remains the same nor that everything in the world remains the same, only the language. The latter line of interpretation may find its analogy in "Physics leaves the world as it is." The part of the *Philosophical Investigations* that deals with "philosophy" identifies the aim as "complete clarity" (PI, # 133). This result is to be reached by specific methods in specific cases.

Wittgenstein states his antitheoretical position where he starts his discussion of “philosophy”:

And we may not advance any kind of theory. There must not be anything hypothetical in our considerations. We must do away with all *explanation*, and description alone must take its place... These [philosophical problems] are, of course, not empirical problems; they are solved, rather, by looking into the workings of our language, and that in such a way as to make us recognize those workings; *in despite of* an urge to misunderstand them. The problems are solved, not by giving new information, but by arranging what we have always known. Philosophy is a battle against the bewitchment of our intelligence by means of language. (PI, I, 109)

Elsewhere he writes, “The work of the philosopher consists in assembling reminders for a particular purpose” (PI, I, 127). A number of questions can be asked: How are descriptions related to generality? And to theories? What is their particular contribution to understanding future cases? Is there a place for the general anywhere in Wittgenstein’s work and thought at all? If the quoted remarks were supposed to describe how philosophy is in fact done by professional philosophers, the remarks are obviously false. Explaining, deducing, drawing conclusions, advancing, and debating theories are what philosophers continually do. But it is important to get clear about what counts as “theory” here. Wittgenstein characterizes a theory as something hypothetical, that explains rather than merely describes, such as causally explanatory generalizations, which are testable by experiment or experience in general. Though something can be explanatory (such as a mathematical proof) without being hypothetical, it seems impossible to do philosophy without theorizing, if something is to count as theoretical when it involves deduction or drawing conclusions rather than just description. However, if we take it that Wittgenstein wants to reserve “theory” primarily for causal explanations that permit hypotheses and testing, his investigations are theoretical in a different sense, in a way he clearly does not want to object to. In what is called the *Big Typescript*, one can find some support for this interpretation: “As I have often said, philosophy does not lead me to any renunciation, since I do not

abstain from saying something, but rather abandon a certain combination of words as senseless... Philosophizing is: rejecting false arguments” (*The Big Typescript*, # 86 and 87; Klagge and Nordmann 1993, respectively, on pp. 161–165). Wittgenstein’s antitheoretical stance is therefore first and foremost an attack on the subsumption of philosophy under science. Philosophical problems cannot be decided by experience; they are conceptual and the result of lack of understanding of the way we talk. Therefore, it has to be demonstrated of philosophical positions (“theories”) that they are flawed in more fundamental ways (that they are meaningless, nonsensical, or incoherent). By pointing out that there is an incompatibility between the use a philosopher makes of a word and the account (the reason why) he provides for its use, a philosophical position can be criticized undogmatically – teaching you “. . . to pass from a piece of disguised nonsense to something that is patent nonsense” (see PI, I, 464).

Wittgenstein’s intent was to show that the criteria of grammaticality are *not* the universal validity and necessity characteristic of the a priori. A philosophical method has to *describe* the language-game itself as the source of meaning of the terms used in it, without more ado. Therefore, *the* description that can establish *the* only possible order does not exist (PI, I, 132). It is only possible to reform language “for particular practical purposes” (PI, I, 132). For Wittgenstein, philosophy is not a set of doctrines, but an activity, and philosophical results are not found in “philosophical propositions,” but in making propositions clear. He insists always on asking whether a word is ever actually used in a particular way in the language-game that is its original home (PI, I, 116) and proclaims that what we are destroying in doing so is nothing but houses of cards, clearing up the ground of language on which they stand (PI, I, 118). Thus as *critique of language*, philosophy is not a reformative undertaking, but a descriptive one, which should show us, for instance, when language is merely idling. The solution of a philosophical problem is offered by reference to what lies open to view – once we are reminded of it (grammar). “Grammar” is lacking in perspicuity, and “perspicuity” basically means

nothing other than an understanding consisting of seeing connections (*PI*, I, 122).

It is Wittgenstein's hope that from reflection upon the very general facts of nature and the formation of different concepts, a change in attitude will emerge toward the concepts we in fact possess. This is a change of attitude in which we stop thinking of our concepts as being either "absolutely correct" or otherwise entirely arbitrary and instead light upon them as bound up with our life and so no less arbitrary or correct than it is. This is a kind of illumination that can be no less important (or urgent or necessary) than the kind that can be provided by empirical research. In philosophical inquiry what we are trying to do is not to discover something of which until now we have been ignorant, but to know better something that in one sense we knew already. Descriptions of the actual use of expressions ("grammar") provide neither a foundation nor an (causal) explanation of linguistic behavior. What lies at the basis of the language-game, and therefore is presupposed to ground it, surely includes the regularity of custom; this represents a foundation only insofar as the network of convictions inside of which we carry on must rely upon it. And the fact that one takes over forms and concepts is not itself conditioned by forms and concepts, but by modes of acting. Again, by indicating that language-games are to be understood within a practice, this should not be understood as implying that they must be justified by something else. It is merely a different way of indicating how language-games cannot be spoken of other than with or within the context of a particular human practice. Therefore, philosophy does not put us in a position to justify or to criticize what we do by showing that it meets or fails to meet requirements we lay down in our philosophizing. In this sense, as Cora Diamond argues, philosophy leaves everything as it is (Diamond 1995, p. 69).

Wittgenstein provided a conception of human life in which the idea that man is a cultural being is taken seriously. Language is, on this way of looking at the matter, a constantly expanding and shifting set of cultural practices. They are ways of behavior that grow out of natural life

through the creative efforts of human beings. "...[P]ractice has to speak for itself" (OC # 139). The concept of "practice," as Kjell Johannessen argues, points not only to the ways in which the unity of our concepts is formed; it also comprises the skills involved in *handling* the conceptualized phenomena, our pre-reflective *familiarity* with them, expressed in the sureness in our behavior toward them and the *judgmental power* exercised in applying or withholding a given concept on a particular occasion (see Johannessen 1988). These factors are all relevant to the establishment of knowledge, but they cannot themselves be fully and straightforwardly articulated by verbal means. It should be noted not only that we have taken over certain ways of judging the empirical world from earlier generations but also that, in this context, judging is a way of acting. The child's coming to act according to these beliefs cannot be learned by learning rules (see OC # 144). It has to be picked up by examples and by training, which are importantly different from conditioning in that the association is structured by a practice (which is for Wittgenstein rule governed, that is, normative: not the mere reinforced association of word and object). Training is successful if it results in the initiate learner becoming skilled and thereby an autonomous practitioner and thus hereafter performing within, and thus adding to, a practice – maybe even contributing to a partial change in it. A necessary support both logically and physically for the novice's linguistic actions is the structuring provided by the community. It is logically necessary because it provides the system of background beliefs, actions, and competencies. This complex pattern is necessary for the token utterance to have significance and so to be an utterance. This is not to say that these practices are forever fixed: they are always open to new developments. These practices are not deliberately chosen conventions, but are constituted by the harmonious "blind" agreement in words and activities of a group of people over a period of time. It is "blind" only in the sense that it does not result from the self-conscious or explicit application of rules (*PI*, I, 219), though this does not mean that people are unconscious automata.

Only within a “language-game” will we be able to justify a certain inference and a certain behavior and can we speak of (lack of) justification, evidence and proof, mistakes, and good and bad reasoning. Investigations and criticisms of the reasons and justifications are brought to an end when we come upon something that we regard as a satisfactory reason and that we do so shows itself in our actions. We are initiated into “language-games” (reference is made to “normal cases”) and thus into judgment(s). He writes: “. . . always ask yourself: How did we *learn* the meaning of this word (“good,” for instance)? From what sort of examples? In what language-games? (*PI*, I, # thus: 77). Wittgenstein argues that dealing with meaning must always come down, at some point, to a recognition that people just *do* accept this or that and just *do* agree about what actions count or do not count as following a certain procedure. Yet at the same time the inherent nature of the language-game is such that meaning cannot be spelled out in terms of essence or in terms of necessary and sufficient conditions. This “leap” however has nothing to do with deliberately looking for a different meaning (wanting to surpass or abandon a previous meaning), instead with not wanting to legislate future use.

Values, customs, and traditions cannot and should not be explained, as J.C. Nyíri argues (1992). Every “explanation” is, as it were, a judgment of reason – but reason itself, as Wittgenstein in his later philosophy sets out to prove, is in the last analysis, grounded in “our acting,” in “what we do,” which in some sense is what “tradition” amounts to. Therefore, if freedom is incompatible with being bound by real tradition, it is incompatible with “reason,” and not conforming must be seen as an anthropological folly – this, Nyíri argues, is Wittgenstein’s underlying thought. Certainly, in Wittgenstein’s work one finds a respect for what is *there*, what is historically given. This is present not only in the conception of the task of philosophy as description but also as the recurrent theme of the analyses: the acceptance of the authority of everyday language – here we reach bedrock or “the riverbed.” Moreover, Wittgenstein’s “Remarks on Frazer’s *Golden Bough*” suggests that he came to think that ethics

cannot be unitary. Taken out of context, this might appear blatantly conservative. His arguments, however, seldom address issues capable of being approached conservatively as opposed to, say, radically or liberally – it is not clear that the distinction applies, not that his work is not normative or that it is value-free. Wittgenstein is preoccupied by problems that are of a different, or more rudimentary, nature than those on which the conservative-radical distinction gains purchase. Furthermore, as Mark Cladis argues, his position endorses internal criticism. And though this may seem unduly limited, it *is* honest and, in contrast to supra-historical criticism, it is not illusory. Becoming aware of the historicity of society and all that this means can assist us in reforming society. This attitude has about it something of the humble wisdom of Socrates: the problems of life have more to do with learning *from* something than with solving a problem and then going on to the next one.

For Wittgenstein, “The child learns by believing the adult. Doubt comes *after* belief” (OC, § 160). The bedrock of our “language-games” is the “form of life.” These unjustified and unjustifiable patterns of human activities can be seen as the complicated network of rules which constitute language and social life. This “given” is a whole: it is the “language-and-the-world”; we cannot place ourselves outside of it. Our acting is embedded in a matrix of certainty that precedes our knowledge (the matrix of knowing-and-doubting and knowing-and-“making a mistake”). The ordinary certainties are the roads on which we walk without hesitation. They are not the only possible ones and not perhaps the correct ones (not even those which have worked in experience). Therefore, in general, “education” from a Wittgensteinian position can be conceived as a dynamic initiation into a “form of life”; parents are seen as the “first educators” and the responsibility of the State concerning schooling can be seen as an extension of this. Educators offer the child the truths by which they live: what moves them, what appeals to them, and what supports the idea of “human being” they offer to the child hoping that she or he will participate. Thus the child is immediately grasped in the human order, structured by certain relationships, and identified by language. If education ought to provoke new ideas, it nevertheless has

to start from somewhere. Its aim is being a personal way of dealing with “what matters”: how people have struggled in the past with what troubled them most and how they dealt with it (a process in which one gets acquainted foremost with questions rather than with answers).

Does the practitioner need a philosophy or a theory of education? There is no reason to doubt what Wittgenstein’s answer to this question would have been. As with any practice, theoretical or philosophical insights are not needed for those involved in order to be able “to go on.” And it is not as if causal explanations would be of any help. But at the same time he would not deny that if one engages in reflection upon these practices, after being involved in particular activities, this might give us a better understanding about what one is doing. Freeing us from the idea that education must have a fixed and unified meaning will change what we want to do in education. This might generate, for example, a different perspective on research concerning day care for young children (now primarily focused on the “effects” this has on the very young) and highlight the way parents see themselves. And philosophy of education might address questions that have to do with means-end reasoning or cultural pluralism. One has to bear in mind however that according to Wittgenstein we do not encounter philosophical problems in practical life. We encounter them only when we are guided not by practical purpose in forming our sentences, but when certain analogies within our language lead us astray (*The Big Typescript*, #91; Klagge and Nordmann 1993, p. 189). Careful reading in this way would not lead to the development of theoretical views, or any such thing, but it would change the *researcher*: the world would come to be looked at differently. And coming to see the world differently is changing oneself.

Anti-colonial Education

George J. Sefa Dei

Nana Adusei Sefa Tweneboah I, Social Justice Education, OISE, University of Toronto, Toronto, ON, Canada

Introduction

Contemporary schooling and education must confront some important questions: How can educators assist learners to reimagine new futures where human lives are transformed in profound, productive, and meaningful ways? How do we begin to talk of critical anti-colonial subjects who would embark on a collective and radical imagining and imagination of new futures? How do we reimagine the school space from an institution that teaches normalized values to one that interrogates histories and addresses inequity? The politics of futurity requires that we bring a critical anti-colonial gaze to schooling and education and the possibilities for producing creative and resisting subjects for change; meaning we must interrogate teaching, learning, and the administration of education not only for their contributions to social success for all learners but also how educational sites make possible a new future. Under the idea of futurity, what becomes possible is a realization the coloniality of schooling and education continues to produce hierarchies and systemic barriers that are very consequential for educational

outcomes for learners. To understand the coloniality of education, we need more nuanced theoretical prisms that offer deeper insights into how schools and other educational sites perform as colonial and imperial agents of society.

Anti-colonialism as a Discursive Framework for Education

The anti-colonial discursive framework helps uncover such colonial relations of schooling and education. It also helps point to directions for resistance, change, and transformation. As argued in other contexts, the “anti-colonial” refers to an approach to theorizing colonial and re-colonial relations and the implications of imperial structures on (a) processes of knowledge production, interrogation, validation, and dissemination; (b) the understanding of Indigeneity as both a process and identity; and (c) the pursuit of agency, resistance, and subjective politics (see Dei 2000, Dei and Kempf 2006). (Subjective politics is the politics of the subject/body engaging questions of how identity is linked to knowledge and political practice.) The anti-colonial brings to the fore questions of colonial relations of knowledge, power, resistance, subject agency, and the place of Indigenous insurgence and resurgences in promoting new futures. In a theorization of anti-colonial, the “colonial” is understood as anything that is “imposed” and “dominating,” rather than simply “foreign” and “alien” (see also Dei and Asgharzadeh 2001). Colonial relations are seen as encounters (lived experiences, histories, resistances) shaped and defined by difference: race, gender, class, sexuality, language, culture, etc. The colonial encounter gestures to the importance of viewing colonialism as more than political domination of Indigenous and colonized peoples. Colonialism is read to imply an unending relation and practice, as something that continually challenges the sovereignty of colonized and Indigenous peoples. Indeed, today colonialism is alive in the denial of Indigenous peoples’ sovereignty and self-autonomy, dispossession of the lands, the displacement of peoples, and the denial of people’s basic humanity, as well as

imperialistic projects that continue to design other peoples futures. There are also the many recolonizing projects that manifest themselves in variegated ways and different contexts through globalism (see also Dei and Meredith 2016, Kempf 2010).

Colonialism and colonial encounters have persistently thrived on exclusive notions of belonging, difference, and superiority Fanon (1990), Grosfuguel (2007). Colonial relations have always sought to establish and sustain hierarchies and systems of power and oppression, denying the hopes, dreams, and aspirations of colonized and Indigenous peoples. Through the colonial vestiges, dominant narratives championing the colonizer's sense of rationality, reason, legitimacy, authority, and privilege are employed to define and script the colonized as the violent "other." The colonizer is pitted as just, innocent, benevolent, caring, and ethical (see Fanon's discussion on Manichaeisms). It is such extended conversations about the nature of colonialism and decolonization that ground current anti-colonial theorization. This theorization must also be taken as an affirmation of the continuing struggles for colonized peoples and communities to purge ourselves of the "psycho-existential complexes" and "psycho-affective features" battered and imprinted on us over the course of the colonial experience and through colonizing and imperial knowledges (see also Coulthard 2007, p. 450).

Dei (2006) notes that contemporary anti-colonial theorizing has roots in the decolonizing movements of colonial States that fought for independence from European countries at the end of the Second World War. The revolutionary ideas of Frantz Fanon, Mohandas Gandhi, Mao-Tse-Tung, Albert Memmi, Aime Cesaire, Kwame Nkrumah, and Che Guevara, to name a few, were instrumental in fermenting anti-colonial struggles. Most of these scholars were avowed nationalists who sought political liberation for all colonized peoples and communities using the power of knowledge. In particular, Fanon's (1967) and Gandhi's writings on the violence of colonialism and the necessity for open resistance and Albert Memmi's (1969) discursive on the relations between the colonized and the colonizer helped instill in the

minds of colonized peoples the importance of engaging in acts of resistance to oppose the violence of colonialism. In later years, particularly in the contexts of Africa, other scholars including Aime Cesaire (1972), Leopold Senghor (1996), and Cabral (1974) introduced questions of language, identity, and national culture into anti-colonial debates for political and intellectual liberation. Furthermore, liberation movements have also sprouted in the heart of empire as evidenced by the works of Malcolm X, Stokely Carmichael (2007), Garvey (2016), and Baldwin (1962) larger movements such as the Black Panthers, American Indian Movement, and the Brown Berets in the United States. These interventions have furthered anti-colonial struggles abroad and within the North American context. Later perspectives have tended to conflate the processes of neocolonialism and postcolonialism. A critical transhistorical approach allows us to work with the discursive knowledge of re-colonial relations, that is, colonialism and colonial relations as unending and ongoing, and hence a need to problematize the periodization of colonial histories Escobar (2004). While anti-colonialism may draw on postcolonial and neocolonial writings and theoretical stances, these frameworks and approaches are by no means synonymous with each other.

Contemporary Anti-colonial Theory

Contemporary radical anti-colonial theory focuses on ways colonial relations have been produced and continue to be reproduced in the present. For example, there are modern-day forms of human oppression and colonial exploitation that bring to the fore issues of colonial and human rights abuses, economic exploitation, commodification of bodies, etc. as transnational corporations and colonial States generate huge profits. Many of the colonial and colonizing practices associated through child labor, forced labor, debt bondage, or indentured servitude are incredibly violent practices that work through colonial structures in service of the empire (Walia 2013, Escobar 2004). For example, transnational corporations operate within nation

[colonial] States to maximize profits by reducing costs through uncompensated labor, low wages, etc. An overwhelming portion of this labor force is deeply racialized and gendered. The interconnectedness of global capital and exploitation of gendered and racialized labor has always been a colonial practice of State and empire building. While today the exploitation of racialized and gendered labor is mainly imagined in the global South context of sweatshops, maquiladoras, and other such mass production spaces, such exploitation is very much present in the global North. It is a feature of modern-day economics, race, and gender politics stepped in global capitalism and Western modernity. There is a powerful global reach of the problem that requires multiple tools of analysis. Anti-colonial and decolonial prisms are powerful lenses of investigation and understanding. The anti-colonial prism helps us to tease out the myriad dimensions of global exploitations by uncovering the experiences of racialized and gendered labor as exercised in numerous sectors including industrial manufacturing, technology, agricultural farm work, and other mass production sites. Throughout these locations, racialized bodies have become disposable, and within the global north deportable, workers. Compounding this is the resulting tensions between the rhetorics/advocacy of change and working politically for meaningful change.

The anti-colonial prism allows us to look at how change emerges from among the colonized and oppressed themselves. It highlights the intellectual and political agency of the local subjects while critiquing the colonial vestiges that often present oppressed, colonized, and Indigenous groups as passive (nonresisting and without agency). For example, in the interdependence of global capital and labor exploitation of racialized and gendered workers, we see how exploited labor (e.g., women) employs their agency in deciding migration and labor paths (Sharma 2005). Whether in sex work, indentured labor, arranged employment, or simply the aid or payment to move across borders, workers are in the know about the oppressive and exploitative trajectories. Yet they may decide it as personal choice with an understanding of what awaits

(a difficult life, though, hopefully, less so than the original or preceding context). The problem is that too often there is the illegalization of labor migrants in global North which constitutes a criminalization of human movement across borders stemming from ongoing colonial relations. Often, the response is to deport these labor migrants as having transgressed spatial borders, and hypocritically such deportation gets seen as saving, particularly through a Western bourgeois lens (De Genova 2005).

Anti-colonialism thus questions the effects of global capital and the ways the global North advances the violence associated with the use of racialized, gendered, and working class labor across geographical spaces Mignolo (2007), Quijano (2007), Rabaka (2011). As noted the nation State is heavily implicated in all of this. And so, as is often the case, we cannot construct the idea of transnational corporations running the world in the absence of colonial States with significant power. Current discussions about forced labor also fit State-run migrant programs. Yet, there is no call to demand nation States/governments to address these inequities. Colonialism, slavery, and racism have worked in tandem, and we are still living with the effects. It is visible, and it must be addressed at multiple individual, local and global levels. Throughout human history, and particularly within settler colonial contexts, Black and Indigenous peoples were and are still required by the project of colonialism to ensure that the nation State retains its control (i.e., control as in over the benefits of citizenship, over the way land is distributed and used, over who has access to social services and employment, over who can afford housing, over who can afford certain kinds of food, etc.). In Canada, for example, Whites did not just colonize Indigenous peoples. The colonial settler State funneled Black and other racialized groups unto Aboriginal soils, seduced *us* [immigrants] with the benefits of citizenship, and capitalized on the exploitation of Black and racialized labor to build the society we have today. Media, popular culture, school textbooks, and in fact the broad school curriculum ignore the dispossession of Black people and, simultaneously, paints a false

portrait of peaceful settlement/relationships. This portrait is a gross misrepresentation of the violence that has occurred to create the nation. All this requires an anti-colonial reading to understand the nature and extent of colonial violence. Similarly, Africans on the continent are still struggling with neocolonial practices that impact on questions of development and human rights with the role and policies of international financial bodies (e.g., IMF and the World Bank) and transnational corporations impacting negatively on African peoples' lives. In Africa, we also have the tapping and draining of local wealth, human resources, and other material resources. And, there is a connection of Africa and African peoples on the continent and in the diaspora.

Race and Anti-colonial Education

Race, colonialism, and oppression worked and continue to work in a powerful tandem, particularly in schooling and education. The problem is that colonial education has worked to erode identities, spiritualities, and sense of communities as vital ingredients of knowledge for understanding our education. Racism was and has continued to be a colonial project. The colonizer does not have to be present for the racist effects of colonization to be felt. We have colonial patriarchal structures and systems set in place to do the colonizer's bidding. The changing meanings and complexities of Whiteness and Blackness do not obscure their saliency in today's sociopolitical contexts. The absented presence of race in educational spaces and the subsequent impact on youth identity formations require that we focus some attention in anti-colonial educational practice for subversion of White colonial dominance. Anti-colonialism therefore necessitates accounting for the normalization and subsequent coloniality of race in institutional settings. In other words, anti-colonial framework rejects the idea that, since race is difficult to define, one cannot disengage from pinning down its legacy. Race is real in its consequences given the power of colonial hierarchies established along the lines of raciality and racialologies. While

schooling is a microcosm of the prevalence of racist structures in society, it also informs and guides much of what we take for granted. Schools are charged with producing "good citizens" and schooling naturalizes hegemonic ways of being and belonging. In short, anti-colonial framework theorizes how dominant schooling does not problematize or interrogate the centering of a White-settler logic. Instead, while masquerading as the space for the development of critical thought, it demands and rewards passive belonging. This process is subtractive. It actively works to remove knowledges, cultures, and pride of one's community and family in the name of civilizing subjects and, as Valenzuela (1999) points out, those who resist these processes are themselves removed from the schooling structure. We must link this to the process school push outs.

Consequently, anti-colonial education connects race and the cultural politics of schooling and education raising new questions: How do we read who is deemed worthy of education by conventional standards? Where is the "multi" in the multicultural space and diverse pluralistic contexts? How do we explain the mystification of Blackness in schooling and everyday social practices? How are discourses of respectability entrenched in schooling and educational to adversely practices affect Black, Indigenous, and other racialized learners? What particular meanings do we bring to the ways racialized, gendered, classed, sexualized identities implicate differential educational outcomes for youth? What are the ways we maintain invisibility of some forms of oppressions and racisms? What type of education should educators provide to learners, and what are learners going to do with such education? What does it mean to create an inclusive anti-colonial global future and the nature of work it requires to collectively get us there? These questions implicate the school curriculum, classroom pedagogy and instruction, and the educational practices required to bring educators, students, and local communities together to break down colonial structures of schooling. These questions are important because colonial education maintains blind spots on particular identities of learners

(e.g., race) and their connections to schooling, education, and knowledge production.

An anti-colonial analysis of education studies how failing to connect race and colonial oppression is a major problem of colonial education. The educational system has not adequately prepared learners to discuss race, let alone how race is rooted in colonization and colonial structures. Most learners are not equipped with the language [vocabulary] to speak, interrogate, and trouble race and colonizing encounters. So it is not uncommon to see even racialized learners shy away from race. When we center race and difference in education, we can also bring new questions to the neoliberal educational agenda. Educators, students, administrators, parents, guardians, community workers, and local communities can challenge our own colonial investments through mainstream educational pursuits. By highlighting democratic education, individual rights, and freedoms, liberal education agenda points to the dialectic of coloniality and modernity and the ways this dialectic informs schooling practices. The power of Euro-colonial modernity does not allow for a reimagining of new/alternative educational and social futures. Western hegemonic systems of thought, ways of knowledge production, and conventional processes of schooling and educational delivery are intertwined to maintain a colonial educational system. Colonial hierarchies and relations of schooling revolve around certain ontological, epistemological, and axiological hegemonic foundations. Conceptions of individual rights, human dignity, liberty, freedom, choice, equality, “autonomy,” justice, virtue, tolerance of dissenting viewpoints, etc., are all relevant. But we need to work politically and collectively to actualize these ideals. Anti-colonial education pays particular attention to the macro-social processes, as well as the economic, political, and psychocultural realms of domination.

Indigeneity and Anti-colonial Education

Another important dimension of contemporary anti-colonial theorizing is the engagement of

question of Indigeneity as an international category. This approach to anti-colonial framework imbricates lessons of Indigenous peoples’ struggles for sovereignty against White colonial settlerhood and other disposessions of Indigenous peoples’ lands and territories across global spaces Tuck and Yang (2012). The occupation is not solely a physical occupation. This expansive reading brings a transhistorical lens to the discussion allowing us to work with the knowledge of re-colonial relations as about loss of land, space, histories of migration, culture and memory, notion of belonging, connected spirits, and identities. In this sense the “anti-colonial” is intimately connected to decolonization and, by implication, decolonization cannot happen solely through Western science scholarship. In other words, the anti-colonial becomes decolonial resistance to the hegemony of Western knowledge and a search for new futures of mutual coexistence.

By moving Indigeneity beyond a strictly genealogical representation of relationship to land, the “Indigenous” is then defined broadly to maintain space for anti-colonial and decolonial thought embracing Latin American, mestizo, “mixed race,” Black, African, Indian, Asian, South Asian histories, and experiences as we confront the question of Indigeneity. Such approach allows for a more critical discourse and practice of Indigenous resurgences and empowers Indigenous peoples everywhere to reimagine a collective future together. It also allows us to push our understanding of decolonization to include culture, space, bodies, the psyche, the internalization of colonial relations of thought, and colonial difference, as well as the intersectionalities of struggles. This is revisioning of decolonization and anti-colonial politics differently and yet converging. Colonized bodies that move into new spaces, usually settler colonial contexts [e.g., racialized immigrants in White-settler communities], do not automatically lose their Indigeneity or Indigenouness (Dei 2016). The colonial encounter did not remove the knowledge base from mind, memory, and soul. Such knowledges can be and are being reclaimed globally as the basis for global Indigenous resurgence.

Computer-supported argument visualization;
CSAV; Diagrammatic reasoning; E-learning;
Graphic representation; Logic; Normativity;
Peirce; Rationality; Software

Introduction

The abilities to argue, to evaluate the quality of argumentative reasoning, and to structure reasoning by means of arguments, all these argument-related skills are crucial not only for the scientific mind but for everybody who strives for a self-determined life without external manipulation, for competent decision making about important matters of life, for self-confident interaction with others, and for participation in public deliberation. Reacting to the need to teach the skills of argument, researchers in the areas of education, philosophy, and computer science developed over the last decades a large number of software tools known as “argument mapping software” or “computer-supported argument visualization” (CSAV) tools.

Based on the fact that any argument needs to be represented in one way or another, and given the large variety of software tools that allow the visualization, mapping, or diagramming of arguments, it turned out to be helpful – especially for the design of future CSAV tools – to study the construction of arguments not only from a conceptual and empirical point of view but also from a semiotic point of view. Semiotics – the theory of signs and representations – should provide important conceptual and theoretical means to understand what happens when people visualize arguments and when they learn by studying and reconstructing arguments.

The following considerations on the semiotic foundations of CSAV tools concentrate on two questions: What can we learn from semiotics about ways to acquire the ability to construct clear and convincing arguments by means of CSAV? How can a semiotic reflection help to determine principles and requirements for the design of argument visualization software? After describing some of the challenges that CSAV attempts to address in education, this contribution differentiates several approaches to “argument” and “argument visualization” in the educational literature and discusses semiotic foundations of CSAV based on Charles S. Peirce’s work on conditions that are required for interpreting signs and for learning by experimenting with diagrams.

Why Computer-Supported Argument Visualization?

The book title *Arguing to Learn* (Andriessen et al. 2003) may be the best expression of the assumption that there is a close relationship between the construction of arguments and learning. This is convincing especially for the learning of scientific reasoning and the content taught in science education. Since in science every theory and every thesis has to be justified by evidence, learning science needs to go hand in hand with learning how to argue.

Software tools have the potential to support the construction of arguments which is especially important in settings where students collaborate on their own in small groups. CSAV can help to scaffold student argumentation by providing specific structures that guide both interaction among students and the construction and experimental manipulation of arguments.

The same functionality of CSAV – providing structure for both interaction and understanding of possible organizations of content – has been the focus of research that emphasizes that an important skill students should acquire is the ability to cope with “wicked problems.” Horst Rittel and Melvin Webber defined “wicked problems,” in contrast to “tame problems,” as those problems whose understanding depends on someone’s point

of view. “There is no definitive formulation of a wicked problem.” “The formulation of a wicked problem *is* the problem!” (Rittel and Webber 1973, p. 161). Based on a variety of different perspectives – each representing specific needs, interests, world views, beliefs, and values of people – problems and possible solutions can be “framed” in a variety of ways.

Rittel and Webber recommended that the multi-perspectivity of wicked problems should be addressed based on “an argumentative process in the course of which an image of the problem and of the solution emerges gradually among the participants, as a product of incessant judgment, subjected to critical argument” (Rittel and Webber 1973, p. 162). CSAV tools promise to support students in their collaboration on wicked problems (Kirschner et al. 2003).

Other educational uses that have been suggested for CSAV include the training of critical thinking and stimulating reflection on the quality of one’s own arguments and reasoning.

Different Approaches to “Argument” and “Argument Visualization”

Available argument mapping software addresses these educational challenges in a variety of ways which are connected to different conceptualizations of what an “argument” is. Three definitions can be distinguished. The first one originates in philosophy. It defines, in one of many similar forms, an argument as a set of one or more premise-conclusion sequences so that either one or more premises are intended to support a conclusion or a conclusion is intended to be justified by one or more premises. A second understanding of argument adds to this first one a focus on the ability to supplement any position with a counterposition (“pros and cons” or “confronting cognitions;” see Andriessen et al. 2003).

A third tradition in educational argument theory uses “argument” in a broader sense that is influenced by work on “wicked problems.” Since the focus is here on clarifying “issues,” many scholars include in the process of argument visualization also activities such as formulating

questions, ideas, pros, and cons, problem solving, the generation of hypotheses and evaluation criteria, expressing doubt and disbelief, and reifying, contrasting, criticizing, and integrating perspectives (Kirschner et al. 2003).

Semiotic Foundations

Whatever definition of argument one prefers, there are at least two areas of theory development in semiotics that can contribute to a better understanding of problems related to learning by means of CSAV on the one hand and to the determination of principles and requirements for the design of argument mapping software on the other. The first of these concerns reflections on the conditions of interpreting signs and representations adequately. Since CSAV is all about visualizing arguments, the problem of interpreting of what can be seen is fundamental. The second relevant area of semiotics discusses conditions of how we can learn and reason by means of external representations via what Charles S. Peirce called diagrammatic reasoning.

Interpreting Signs and Representations

Charles S. Peirce – who was the first in modern times to develop the fundamentals of semiotics from a philosophical point of view – always claimed that a sign fulfills its function to represent something for someone (or for something other) as “a medium” that is embedded in a triadic relation: it is determined by its object and it determines its “interpretant.” Later in his life, Peirce understood this “interpretant” in a rather formal sense as “the proper significant outcome of a sign” or its “proper significate effect” (Peirce, 1931–1958, CP 5.473 and 475). However, if we ask what it takes to interpret a sign correctly, then it seems necessary – as Hoffmann and Roth (2010) argued – to take a fourth element into account besides object, sign, and interpretant: background knowledge about the sign’s meaning that someone needs to activate in order to either interpret a sign according to what he or she already knows about it or create new meanings. Peirce described this – very late in his life – as

“collateral knowledge” and argued that “no sign can be understood... unless the interpreter has ‘collateral acquaintance’ with every object of it” (Peirce, 1931–1958, CP 8.183).

This insight is indeed crucial for teaching. When we teach the analysis or construction of arguments, we talk about “reasons,” “conclusions,” and other things we take for granted, but do we really know that students interpret these concepts in the same way we do? A case in point is Deanna Kuhn’s famous study on the skills of argument that demonstrated that 60% of participants were not able to provide “genuine evidence” for a theory they themselves formulated to explain things such as school failure and unemployment (Kuhn 1991). Looking at the transcriptions of some of the interviews her team conducted, it seems more likely that many of the participants simply didn’t have any clue what the term “evidence” really means and what the difference is between answering the question “how do you know that this is the cause” and just telling a story about a causal relation.

For the design of CSAV tools, the insight that the correct interpretation of signs and representations depends on the availability of the right collateral knowledge is particularly important for the graphical elements that are used to visualize arguments. For example, it seems obvious that the separation of reasons and conclusions into different text boxes helps students to “see” the structure of an argument. However, it might not be clear what exactly the meaning of the arrow is that connects these text boxes. Does it mean “therefore” or “because”? Even if the direction is clear, the arrow alone is not sufficient to distinguish in the case of $p \rightarrow q$ between “ p therefore q ” and “ p since q .” In the first case p is the reason, while it is the conclusion in the second case. Thus, it might be helpful to provide necessary collateral knowledge in the representation itself by naming graphical elements explicitly, for example, by adding “therefore” or “because” to arrows.

The Rules of Representational Systems

A second area of semiotics that is relevant here is informed by Peirce’s work on “diagrammatic reasoning.” It is relevant especially for a better

understanding of how students can learn how to improve the quality of their own arguments and for a better understanding of how CSAV can support them in their efforts. Diagrammatic reasoning is reasoning by means of representations which visualize, in particular, structures and relations. A central idea of diagrammatic reasoning is that an external visualization of what we think about the issue in question allows us to identify problems and gaps in our own thinking, leads to the identification of relations we were not aware of before, and stimulates thus creativity and learning (Stjernfelt 2007; Hoffmann 2011; Semetsky 2013).

A “diagram,” for Peirce, is a representation whose main function is to represent a certain group of relations, namely, those relations that are rationally comprehensible. Relations are rationally comprehensible if they can be represented in a “consistent system of representation” (Peirce, 1931–1958, CP 4.418).

The rational character of diagrams is crucial for diagrammatic reasoning. Peirce defines diagrammatic reasoning as reasoning with diagrams that are constructed by the means provided by a certain system of representation – be it a logical system, or an axiomatic system as in geometry, or simply the vocabulary and grammar of a language. Such reasoning with diagrams is realized when we experiment with a diagram according to the rules of the chosen representational system. Experimenting with diagrams, transforming them according to the rules of the system, and observing what happens are crucial for scientific discoveries and the development of new knowledge. The reason is that such experimentation can lead to the discovery of regularities and of “relations between elements which before seemed to have no necessary connection” (Peirce, 1931–1958 CP 1.383), which again can lead to the creation of new concepts and theories. Examples in the history of science are the discovery of incommensurability in geometry and irrational numbers in arithmetic, the formulation of Desargues’ theorem in projective geometry, and Maxwell’s development of the electromagnetic field concept. In all these cases, it is important that the discovery of something new is

conditioned on the rules of the chosen representational system. If there were no rules according to which experiments are performed in diagrammatic reasoning, it would never be possible to distinguish arbitrary observations from those that can be used to create new knowledge.

In the context of education, and especially considering an edusemiotic perspective taken by educational theory and pedagogical practice, the discovery of new knowledge is no less important than other significant functions of diagrammatic reasoning: to structure and organize one's reasoning and to support the evaluation and improvement of reasoning. Diagrammatic reasoning can help students to reflect on their reasoning without being constrained by the limits of their working memory, analyze a problem more thoroughly and systematically, clarify and coordinate confused ideas about a problem, clarify implicit assumptions, identify background knowledge that might be inadequate, structure a problem space, change perspectives, identify unexpected implications, play with interpretations, discover contradictions, and distinguish the essential from the peripheral (Hoffmann 2011). However, a precondition for reflecting on one's own reasoning process by means of diagrammatic reasoning is that students have clear standards at their disposal to evaluate the quality of their reasoning. There need to be criteria with respect to which reasoning can be assessed. Those criteria are given in the rules of the representational systems according to which diagrams are constructed and experiments performed. Logic, for example, provides rules that can be used to perform self-controlled reasoning. We control our reasoning by comparing it with the norms of logic.

Logic, however, is only one possible normative standard for self-controlled reasoning. The "critical questions" that Douglas Walton and his colleagues developed for each of a multitude of different argument schemes fulfill the same function (Walton et al. 2008). They provide a standard that students can use to assess – and to improve, if necessary – the arguments they encounter or create.

A major opportunity that CSAV provides in this regard is that the rules of representational systems can be implemented in the user interface

of software. This has been done, for example, in the collaborative argument visualization software AGORA-net (<http://agora.gatech.edu/>). Here, the user needs to select a logically valid argument scheme to complete the construction of an argument. This selection creates automatically a further premise which transforms the given argument into a logical argument, directing thus the attention to the question how premises and conclusion should be formulated or the structure of the argument changed, to create a more convincing argument.

What edusemiotics, and specifically the semiotics of Charles S. Peirce, can show, thus, is that a necessary condition for learning something by means of diagrammatic reasoning is knowing and accepting the rules of a chosen system of representation, a system by means of which diagrams can be constructed and experiments be performed. Such a system *constrains* reasoning in a way that our cognitive energy gets focused on points that are crucial for reflection on one's own reasoning – just like a fireman's jet of water will be the more focused the more it is constrained. Without any constraints there would be no direction for our reasoning.

Conclusion

"Everybody takes the limits of his/her own field of vision for the limits of the world," wrote Arthur Schopenhauer. Education always aimed at extending the limits of our vision and at broadening our horizon. But how can we teach the abilities to recognize and to overcome cognitive limits in a more focused way? Computer-supported argument visualization (CSAV) has been proposed as a method to support the development of these abilities. Not only does CSAV promise to support the development of argumentation skills – that is, the ability to construct clear and convincing arguments and to evaluate the quality of arguments and argumentative reasoning – it also promises to stimulate self-reflection, creativity, and cognitive or conceptual change. When we use argument mapping software to support a position on an issue or to justify a thesis, claim, or

recommendation, we can learn something about our own thinking. Every argument that we construct shows what we know, what we believe, and often also which values or ethical principles drive our reasoning. Argument mapping, thus, allows us to reflect on our knowledge, beliefs, and values and on how they are related in argumentative structures.

Additionally, graphical representations and diagrams in general, and argument mapping in particular, can help to represent scientific controversies and dilemmas and to structure planning processes and deliberation. And it can teach students the ability to cope, in collaboration with others, with wicked problems and to resolve conflicts that are determined by clashing values, ideas, and world views.

Since the “visualization” in “argument visualization” is crucial for CSAV, semiotics has been proven to be an important theoretical tool to reflect on some of the foundations of CSAV. As edusemiotics in general shows, representations have to be interpreted, and representational systems have certain cognitive effects. To understand how CSAV affects learning and how CSAV should be designed to achieve and optimize certain educational effects, semiotics can play an important role.

Asperger and the Framing of Autism: His Legacy and Its Philosophical Commitments

Glenn M. Hudak

University of North Carolina at Greensboro,
Greensboro, NC, USA

Hans Asperger (1906–1980) is credited along with Leo Kanner (1894–1981) as one of the “discoverers” of autism. Asperger’s pioneering work was published in 1944 as a Habilitation, a second dissertation at the University of Vienna. Kanner’s work, on the other hand, was published a year earlier in 1943 in America at the Johns Hopkins clinic in Baltimore. Uta Frith notes while Kanner

enjoyed wide success, Asperger remained relatively unknown, if not ignored. Indeed Asperger's path breaking dissertation "'Autistic Psychopathy' in Childhood," (Asperger 1991) was not translated into English until 1991 by Frith herself, some 50 years after the original German publication. It is a remarkable coincidence then that both described independently a type of troubled child that no one paid attention to prior to the label autistic. Both were in agreement regarding the difficulties in the children they studied: awkward social interactions, difficulties in communication, resistance to changes in routine, and a clear separation from schizophrenia patients. There is nonetheless, clear distinctions between the two. All in all Kanner's study presents stereotypical portraits of the children as a means to identify a *specific class of individuals*. While Asperger, on the other hand, accented adults and children who were described as socially awkward, highly *idiosyncratic individuals* as they could have vast interest and knowledge in specialized, esoteric fields and yet have difficulty navigating the events of daily living. While Kanner's career is well documented, Asperger's influence and hence his legacy is still very much in the making as new documents have been uncovered that were presumed lost due to the bombing of the *Heilpädagogik* Station in Vienna where Asperger worked during World War II.

Asperger's "Discovery" of Autism: Context & Legacy

Hans Asperger began his career working with children who displayed unique behaviors at the *Heilpädagogik* Station in Vienna (Silberman 2015). The *Heilpädagogik* Station was a children's health clinic founded in 1911 at the University of Vienna by Erwin Lazar. The clinic too was unique in that it brought together psychology, medicine, and progressive methods of teaching to children who were thought by their parents and teachers to be difficult to be around. The concept of "*Heilpädagogik*" means therapeutic education, and for Lazar the best therapy was of the type that fostered a community of mutual respect and appreciation between the clinic staff and the

children. Rather than focusing on individual pathology, he believed in offering the children companionship where the children could feel at home. As such, the clinic's approach was to observe the children throughout the day, when eating, at play, in class, etc., to gain a more comprehensive, holistic portrait of the child. The clinic then both observed the children in their daily interactions while offering a full schedule of courses in math, handwriting, history, geography, and field trips into the clinic's garden. There was plenty of time for rest and "free time" to do as they pleased.

Of key importance is newly found document written by Joseph Michaels (Silberman 2015) who visited the clinic in the mid-1930s. Michaels notes that the Station's staff did not use descriptive categories like "normal" and "abnormal" to describe the behaviors of the children as the staff felt they were theoretically unclear, and practically it is of no importance. He notes children were given maximum freedom of expression and the children learned at their own pace, while staff provided an assortment of toys, building block, cooking utensils, to play with. The children were free to let their imaginations track in a direction of self-interest, and while the children were activity engaged Asperger and his staff made careful qualitative descriptions of the child's behavior. As Michael noted the clinic's approach seemed, "more like art than science."

In Vienna, Asperger worked with over 200 children at the *Heilpädagogik* Station. (see also, Feinstein 2010) At the station these children were described as socially awkward, intelligent, and finding unique ways to solve problems. As such, Asperger viewed the quirkiness of his students in a positive light and as something that should be treasured, not destroyed. He is quite clear in his study that these children exhibited "special achievements" and originality in thinking, as Asperger observes that their thoughts can be unusually rich. They are good at logical thinking, and the ability to abstract is particularly good.

Asperger called this special mode of thinking, "autistic intelligence" and felt such intelligence was undervalued in society. In his study he emphasizes, "Autistic children produce able original

ideas,” inserting that they can only be original, and mechanical, rote learning is hard for them. Later in 1953 Asperger wrote, “It seems that for success in science and art a dash of autism is essential” (Silberman 2015). Indeed, for Asperger the autist’s ability to turn away from the everyday world, from the simply practical, provided them with mental space to rethink a subject with originality so as to create “new untrodden ways.”

Uta Frith (1991) points out, that he was a champion of the children he attended to, advocating for their recognition, pointing out they had much to offer society with aid from teachers who could provide a special type of education. She notes that he feared that teachers and other students often misunderstood these children and suggested that one needs a “dash of autism” to really be engaged to teach these children. Indeed, Asperger believed that the children he worked with displayed original thinking that was found in the sciences and that their introversion was due in part to their inability to learn by conventional means. While Asperger emphasized the strengths of these children, he neither romanticized nor idealized their impairments. Asperger was cautiously optimistic in his appraisal of the children as he felt that their detachment from the everyday, their capacity to get “lost in thought” resembled a scientist who becomes obsessed with a particular problem to solve, hence losing track of the time of day, or of those around him or her.

Indeed, the children Asperger described and the way in which he described the children in his study lead Lorna Wing in 1981 to suggest an “Asperger Syndrome” (Silberman 2015). Wing’s insight into Asperger’s study lead her a few years later to rethink autism reasoning that the phenomena described by Asperger was not symptomatic of an illness nor as a single, monolithic phenomena as Kanner suggested. Instead, Wing conceived of autism as being on a “spectrum,” a continuum of behaviors, dispositions, and intellectual capacity. That is, Wing argued for an incremental gradient for thinking about autism that would align with her interpretation of Asperger’s descriptions. This gradient would allow for a more nuanced notion of autism that could accommodate the idiosyncratic and eccentric child described by

Asperger. Hence opening the door, so to speak, for greater recognition, as Asperger asserted earlier that the character traits described in his study could be found in the “normal” population. Through the efforts of Wing, Frith, and others, a separate strand of thinking about autism began to emerge, a strand that has roots in Asperger’s study.

Steven Silberman (2015) documents the evolution of Asperger’s framing of autism as an elastic concept, multidimensional in its attempt to bring together the materiality of the brain with its interaction with social world. Silberman claims that Asperger’s conception of autism is representative of a unique mode of thinking: neurodiversity. The term neurodiversity appears to be coined by Judy Singer, an Australian college student in the late 1990s. As Silberman points out Singer’s hope was that by honoring diversity, “neurological pluralism,” within the disability rights community it would become a rallying cry for political activism. It was during the 1980s–1990s that autism authors appear on the literary scene, writing about their experience of autism and the challenges they faced both on the personal as well as the political levels of daily life. Works by Temple Grandin, commentaries by Oliver Sacks, Donna Williams, and others helped to establish that autism was not a disease to be cured but rather a way of living and being in the world. As autistic authors began to speak out, it was clear that they sought to reverse the dominant conception of autism as an individual aberration by shifting in emphasis in the discussion as to how society will address the challenge of neurological diversity.

Interestingly, Silberman finds the origins of this call for autistic inclusion lodged within Hans Asperger’s notion that people with autistic traits have always existed within society. From Asperger’s perspective, the autistic traits he observed were always a part of the human condition. The problem is not about autistic uniqueness, rather it is over how society will provide inclusive environments that allow for and accept neurodiversity. With neurodiversity, Asperger’s legacy moves from the idiosyncratic conception to the pluralistic notion of autism that is

highlighted by the autistic rights movements that utilize digital technology to organize and combine insights and energy to challenge ableism. One group, Wrong Planet (started by Alex Plank and Dan Glover, cited in Silberman 2015) argues that the point of their activism is to alleviate those with Asperger's the societal pressure to conform and to utilize their uniqueness as a means to take part in and find their place in the world.

Silberman ends his study with a nod to Asperger, noting that in 1938 Asperger was somewhat prescient in insisting that the traits of autism are, "not at all rare." And second, that autistic people have always been a part of human history, it is not a new phenomena – neurodiversity is an aspect of the human condition. The problem is rather that the ableist ideology continues to frame autism as an aberration, a unique disorder created within the context of contemporary capitalist society.

The challenge for autistic rights group, like Autistic Self Advocacy Network (ASAN), has been assert their presence challenging ableist assertions that autism is a contemporary aberration with their motto, "Nothing about us, without us" (Silberman 2015). Asperger would certainly agree with this motto, as he considered the children he worked with at the Station, not as patients to be cured but rather as colleagues working together. For as Silberman points out, Asperger saw them "indispensable allies" in the development of pedagogy strategies that would be most appropriate and effective for them. Asperger viewed these children as both friends and colleagues, in short as members of a community of thinkers.

Hans Asperger and Disability Studies

While Frith and Wing were amongst the first researchers to bring Asperger's study into the mainstream, social critics like Steve Silberman are filling in the gaps regarding Asperger's place in the current thinking revolving around autism. It is also important to situate his framing of autism within the context of Disability Studies. Traditionally there are two competing models that stage contemporary Disability Studies, on the one

hand the *medical model* and on the other the *social model*. The medical model focuses on the individual body and takes a biological orientation focusing on disability as an embodiment that requires medical intervention. The later, the social model is orientated towards the social and environmental factors that construct disability as a pathology, and hence requiring political interventions at the level of social justice to rectify the negative characterization of disability. The gap between these two models creates conceptually, a binary in thinking about disability: either disability resides in the biological, and medical, or the category of "disability" is a social construction constituted by and through dominant ableist ideologies. The former model frames disability as an aspect of "nature," of our genetic makeup that has become aberrant and in need of medical attention. While the latter model focuses on the ways in which our very thinking about disability is framed, articulated through ableist discourses that ultimately oppress and marginalize those labeled disabled.

In an attempt to bridge the gap between these two models, one disability theorist Tobin Siebers (2011) advocates for a "theory of complex embodiment," which draws on the feminist philosopher, Patricia Hill Collins notion of intersectionality. In his theorizing, Silbers attempts to bring into conversation the two dominant models by exploring the intersectionality of the material body with social representation. Siebers argues on the one hand that there is a need for a greater awareness of the materiality of the body, citing the chronic physical pain experienced by those with physical impairments. Simply to talk about oppressive ableist discourses does not alleviate chronic physical pain. And on the other hand, he affirms: (1) the necessity of critique as knowledge about ourselves and the assumptions held are always socially situated within a specific historic context, hence never neutral; (2) this knowledge embodies complex theories about one's identity and social reality, hence a question of human "value" needs addressing; and (3) acknowledging the political reality that those labeled "disabled" are excluded, marginalized, and oppressed by the prevailing, ableist ideology of the time. As such, the very positionality of the excluded, the marginalized, becomes the focal

point for critique of the dominant ableist ideology. For Siebers “disability” becomes an identity whereby the members of the disability community are recognized as members of society, members who have agency as they are producers of knowledge and actors for social change in their own right.

Finally, Siebers grounds his theory of complex embodiment, and hence Disability Studies, within a “realist” framework. That is, for disability theory to have teeth it must embrace both the concrete material realities of those with physical and mental impairments while actively working towards political change that advocates for a reframing of the discourse around disability that entails more inclusive social environments. Here realism is understood as neither positivistic assertion that reality can be understood unmediated by social representations (what you see is what you get) nor can reality be understood simply as a set of discursive claims unaffected by “real” objects, i.e., the materiality of the body, the brain, the physical world. Hence, Siebers proposes that both the material world and social representations push back on each other, producing the interplay of embodiment with the construction of a shared reality, whereby the materiality of the body and the social world are always in interaction with the construction of socially situated knowledge.

Thinking retrospectively, we can ask how Asperger’s framing of autism align with the realism of complex embodiment advocated by Siebers. In addressing this question we need to keep in mind, on the one hand, that Asperger never claimed to be a realist nor theorized about complex embodiment. While this is the case, it is one of the tasks of philosophy of education, on the other hand, to take the opportunity to speculate as to the conceptual moorings that hold together Asperger’s project by bringing it into conversation with a leading theorist.

Indeed, there is no easy fit between Asperger’s framing of autism and Siebers theory; however, circumstantial evidence suggests that Asperger’s framing can comfortably rest within a realist conception of disability. To suggest that Asperger was something of a realist demands, according to Siebers, that Asperger’s framing of autism satisfy

the requirement that there is an acknowledgement of the “real,” not as unmediated reality, rather as understood in and through socially constituted concepts. That is, the “real” is never seen as it is (naïve realism), rather it is understood, mediated through concepts.

On this point, Uta Frith (1991) points out that Asperger was convinced that autism had a material base, and that there were organic and constitutional factors that were the causal roots to autism. In short, Asperger would agree with neuroscientist that in thinking about autism, the brain in its materiality matters. That problem for Asperger, however, was not that brains think differently rather it was society’s injunctions that insist on there being one “normal” brain that frames any neurodiversity as “abnormal.” For Asperger, diversity was not a problem, it simply exists. And this diversity as pertains to autism has always been a part of human history. Diversity as pertaining to autistic traits is not a pathological state to be cured. Hence for Asperger, as with Siebers, the problem falls into the hands of society.

To be sure, Asperger did not romanticize the impairments he described at the Station. Utilizing the medical concepts of his day, he was acutely aware of physical and mental limitations of the children. (*Here we too need to not romanticize Asperger and keep in mind that the very terms employed were framed within the medical model, hence have a reactionary rather than liberating effect when read today.*) Yet despite this, his efforts were aimed at acknowledging autistic uniqueness, and what they can contribute to society on their own terms.

Unfortunately his plea for acceptance of these children went unheard. Steve Silberman (2015) states that the children’s hospital became the primary children’s killing ward for all of Austria. Over a 5-year period, 789 children were murdered at the facility. Most of the children were diagnosed as “feeble-minded,” “epileptic,” or “schizophrenic”—the three diagnoses that children were most likely to receive prior to Asperger’s usage of the term “autism.” Part of the Nazi eugenics program was to eliminate these children, as they were perceived as a burden on society.

And Asperger? Silberman notes that Asperger refused to report his children to the Reich committee, and twice the Gestapo came to the clinic to arrest him. Twice his superior intervened to protect him!

As such, Asperger's framing of autism was something more than a mere "discovery" of a "new illness" affecting "troubled children." In an important sense, his work sought to "interrupt" Nazi eugenics. That is, Asperger was very aware of the current medical usage of the term autism (1991). Originally coined by Eugene Bleuler in 1919, it was associated with schizophrenia. Initially Asperger sought to separate autism from schizophrenia, which he did successfully. However, with the coming of the Nazis to Austria, his work took on yet another, nonmedical dimension: the term "autism" became a political category that gave recognition and status to the children he worked with.

Asperger did see these children as "special." Yet within his context, "special" was not intended to signify a social classification; it signified uniqueness. Further, the term autism became a part of a political struggle – literally for the survival of the children at the Station – as the term "autism" sort to rename the children. In doing so, it brought them into the presence of others as valued members of their community at the Station. Indeed, prior to Asperger's and his colleague's recognition of autism as a valued trait, the children of the clinic were viewed by the Nazis as inferior, hence disposable.

In sum, when situated within Disability Studies, Asperger's study provides a realist conception of autism: one that does acknowledge the materiality of the body as well as the social construction of knowledge situated within a concrete historic context, and a tacit political awareness necessary to challenge oppressive political ideologies and their egregious practices.

regards to educator's efforts for more inclusive environments. Asperger was a realist. He framed autism from a realist orientation, affording the term with multiple, interlocking dimensions. Asperger initiates thinking about autism that can neither be reducible to the material brain nor to harmful social constructions. Instead, Asperger initiates thinking about autism as a complex embodiment that is a part of human diversity. He tacitly urges us to think of inclusiveness in Gert Biesta's terms, as allowing for the "incalculable" (Biesta 2010). That is, to include that which cannot be known in advance, hence an inclusion that has potentiality to transform the existing order. For Asperger, autistic traits were always a part of the human story, yet remained relegated to the margins of society, hence undervalued. His legacy aims at affording the children the space of plurality whereby diversity flourishes alongside our concerns for social justice. Indeed, his legacy highlights the primacy of moral responsibility and the obligation for the educator to guarantee the safety of our future generations.

Assessment and Learner Identity

Gordon Stobart

University College London, London, UK

The individual in contemporary society is not so much described by tests as constructed by them. (Hanson 1994)

Synonyms

Cultural activity; Evaluation; Student identity

Introduction

Standardized assessments play an ever increasing role in modern society. They often determine the life chances of those assessed, shaping learner identities. Assessment is a social activity and is value laden, despite attempts to make it seem objective and neutral. The appeal of testing, particularly in relation to selection, is that it is fairer than other methods. However, it has sometimes made claims that are hard to support, for example, the inferences drawn from intelligence tests, which have profoundly affected learner identities. Ways in which assessment can contribute positively to learner identities are then considered.

Assessment as a Social Activity

Assessment is a social activity which has always been part of the fabric of life. Used in the broad sense of gathering information to make judgments, it has been part of decision making through the ages. Where to start a settlement or deciding who is innocent or guilty are these kinds of judgments.

While this is still the case, for example, in risk assessment or legal procedures, the focus has shifted to the deliberate gathering of information to make judgments about individuals or groups.

The most familiar of these are the tests used for selection or to determine competence. These are tests which are deliberately designed to gather specific information about individuals so a judgment can be made, for example, about whether they should be selected for progression to a particular institution or be allowed to practice in an occupation.

When used for selection, these assessments have essentially become written, standardized tests, a tradition which stretches back over a thousand years to the Chinese Civil Service selection tests. Standardized testing has seen an exponential worldwide growth over the last hundred years and has become a major industry, particularly in the United States. These tests have increasingly become assessments of achievement, how well the curriculum is known or skills mastered, though generalized ability/intelligence tests still play a powerful role in some cultures (see below). Occupational assessments for the “license to practice” generally involve practical elements as well, for example, medical practicals or making a product (a tradition which goes back to the medieval guilds).

Assessment has increasingly become a powerful social tool because of the consequences for the life chances of those assessed. Failing a selection test when 11 years old has meant for many children either no or limited secondary education, just as passing examinations at 18 may lead to a university place and better job opportunities. These are the “high-stakes” assessments which have such serious consequences for individuals and which shape their identity as learners.

Tests as Fairer and More Meritocratic

How do such assessments come to have this power? The key appeal has always been that they are the fairest way of selection as they rely on *individual merit* rather than patronage or family connections. In this way they have provided opportunities for many who would not have had access to selection by patronage. It is estimated that in the Chinese Civil Service examinations of the Ming Dynasty (1368–1662) up to 60% of the

successful candidates were not from the families of the administrative elite (a better ratio than today's administrations?).

However, just because candidates all take the same test at the same time under the same conditions does not automatically make tests fair or meritocratic. Throughout the history of such testing, certain groups have been excluded from entry. Gender is the most obvious example, with females excluded from most selection tests well into the twentieth century. There is a similar history for lower social classes (slaves, laborers, and actors could not enter the Chinese examinations) and for racial and religious groups. This sends the identity message that these groups are not capable of doing this kind of work.

This has been compounded by the neglect of differences in preparation for the test. Those who had a privileged preparation for tests as a result of elite education would put their success down to merit; they performed better than others, rather than to advantaged preparation. This in turn fed into beliefs that the privileged had more natural ability than the disadvantaged, beliefs which fed into identities of social superiority. The worldwide phenomenon of an exam preparation industry funded by more affluent parents and operating outside regular schooling is part of this. Affirmative action programs for such as university entrance have recognized this problem by allowing for imbalances in the quality of schooling, often meeting opposition from the privileged elite.

Bias. Linked to this is the issue of the fairness of test content. Tests can never be culture-free, so whose culture is being tested? This is about *bias* in testing. Does one item advantage a specific group by assuming a particular cultural knowledge, for example, a particular interpretation of a country's history or literature? There are now techniques for identifying those biases which favor one group against another, for example, Differential Item Functioning – DIF, but these may still underestimate bias within the broader curriculum. We also know that the mode of assessment will affect results, for example girls are likely to perform better than boys on open-ended writing tasks while some students will do better on practical projects rather than tests.

Assessment as a social rather than objective activity. The development of measurement techniques ("psychometrics") to improve the quality of standardized tests has led to the perception that assessment is a neutral "scientific" activity rather than a socially constructed process. This positivistic position assumes that tests are simply measuring "what's there" and are independent of it. So psychometrics is presented as a scientific and detached measurement activity.

The more sociocultural position adopted here is that any assessment is essentially a social activity, so that what is assessed, how it is assessed, and how the results are interpreted are all value-laden social activities. There is no such thing as culture-free assessment – even nonverbal tests involving abstract mental reasoning (for example Raven's Matrices) are rooted in particular cultural understandings and experiences.

Assessment Identities

Because assessment is a social activity, it shapes how individuals and groups see themselves. The philosopher of science Ian Hacking writes about how "sometimes our sciences create kinds of people that in a sense did not exist before. This is making up people" (2006, p. 2). He applies this to conditions like Multiple Personalities which was "discovered" in the 1970 and saw a dramatic increase in people with the condition. More contemporary examples might be the way in which increasing number of children are identified as "dyslexic", or having Attentional Deficit Hyperactivity Disorder (ADHD), or Asperger's syndrome. This is not to say that such children do not have reading, attentional, or interactional difficulties, but the labels we choose and how we respond to these labels is a social process. Hacking identifies ten "engines of discovery" that drive this process. These are 1. Count, 2. Quantify, 3. Create Norms, 4. Correlate, 5. Medicalize, 6. Biologize, 7. Geneticize, 8. Normalize, 9. Bureaucratize, 10. Reclaim our identity. These offer a useful framework with which to understand how educational assessments can shape learner identities. They fit particularly well with

the development of intelligence testing, a form of testing that has had a powerful impact on the identities of individuals and groups for over a century.

Intelligence Testing: A Case Study in “Making up People”

In 1923 Edwin Boring defined intelligence as “what the tests test”. This is more profound than it first appears as it signals that how we understand intelligence is largely the result of how it has been tested. What is included in an intelligence test in turn involves social judgments about what the concept of intelligence represents.

The history of intelligence testing is instructive in understanding this. Intelligence testing as we know it began with the work of Alfred Binet and Theodore Simon in France at the beginning of the twentieth century. They were looking for ways of identifying children in Paris who, with the introduction of universal primary education, would not be able to cope with regular schooling and may need specialist help. Binet took a pragmatic approach to the development of his tests which focused on what was required for school-based learning. In terms of the “engines of discovery,” he used the first four processes to construct his tests and to provide a “mental age.” His social philosophy was that intelligence was “the capacity to learn and assimilate instruction” (1909, p. 104), and the task of educators was to improve pupils’ intelligence and he himself developed “mental orthopedic” exercises to help with this.

Binet’s tests became the basis for many tests in the English speaking world, the Stanford-Binet intelligence test was widely used test throughout the twentieth century. However in the hands of Anglophone psychologists and statisticians with very different social views to Binet about the nature of intelligence it was, in Hacking’s terms, medicalized, biologized and geneticized. Statisticians such as Francis Galton, Charles Spearman, and Cyril Burt in England and Louis Terman and Edward Thorndike all had strong beliefs about the inherited and fixed nature of intelligence. Intelligence was reified (it is a physical entity somewhere in the brain) to something that could be quantified and standardized, using statistical

techniques that they developed. Their philosophical beliefs underpinned these developments – intelligence was inborn and fixed, the successful, including certain races, had more of it. The poor were as they were because of limited intelligence which they then transmitted genetically to their children. While presented as objective scientific findings, they reflected deeply held cultural beliefs evidenced by the proponents’ involvement in social programs related to them. Galton coined the term “euthanasia” and wanted the breeding of the poor restricted, as did Terman in the United States who also called for restrictive immigration laws. These claims have not gone away – they are echoed in best sellers such as Herrnstein and Murray’s *The Bell Curve: Intelligence and Class Structure in American Life* (1994).

Intelligence testing became part of the social fabric in many countries (Hacking’s “normalize” and “bureaucratize”). In the UK, it was widely used for selection to secondary school; the 11+ test used the standardized scores to select the top twenty per cent or so of students for a prestigious grammar school education. It was also widely used in job selection and for identifying pupils in need of special education.

The issue here is how a single test can shape the life chances and identities of cohorts of students. To fail the 11+ sent a signal to the student that they did not have the capacity for academic study – in Patricia Broadfoot’s words “Intelligence testing, as a mechanism of social control, was unsurpassed in teaching the doomed majority that their failure was the result of their own inbuilt inadequacy” (1979, p. 44).

While the claim that intelligence was a unitary “hard-wired” capacity (Spearman’s “g”) has dominated much Anglophone culture, there have always been those who have opposed this interpretation (“reclaim our identity”). Statisticians such as Louis Thurstone used different statistical techniques that produced seven primary abilities that were independent of each other and could not be aggregated into a single scale. Also in this tradition is Howard Gardner’s *multiple intelligences* which present eight separate intelligences, for example linguistic and bodily kinaesthetic, which cannot be simply assessed

by pencil and paper tests or put on a single scale. Daniel Goleman's influential *Emotional Intelligence* (1995) attacked the notion that intelligence test score (IQ) was the critical measure as our social intelligence was more important to success.

Other cultures do not assume that intelligence is fixed at birth and are closer to Binet's more pragmatic concept of malleable intelligence. For example, Confucian heritage societies, with their emphasis on effort and motivation to improve, see intelligence as something that can be developed

Achievement Testing and Identity

In our current education systems, there has been a reduction in the reliance on intelligence testing for selection, though it has sometimes been replaced by "ability tests" which closely resemble them and which produce a less emotive reaction. There may be many reasons for this decline, not least the move to more comprehensive secondary education systems – so there is not the same need for selection for types of school. It also represents a lessening of confidence in IQ scores as their claims and predictive accuracy have been challenged.

It has increasingly been recognized that ability scores are *indicators* of general achievement rather than the cause of it, this is why they correlate well with school achievement. Robert Sternberg, a leading intelligence researcher, concludes that "what distinguishes ability tests from other kinds of assessments is how the ability tests are used (usually predictively) rather than what they measure. There is no qualitative distinction between the various kinds of assessment. All tests measure developing expertise." (1999, p. 60)

A good example of this is the shift in claims about the SAT test in the United States. This is a test taken at the end of high school which is important in the college application process. The SAT began life as the Scholastic Aptitude Test, an ability test to predict college success. In 1990 it changed to the Scholastic Assessment Test because it was recognized that it could not be accurately described as an ability test as it also

measured achievement. By 1997, even this title was thought to be unhelpful and so the letters SAT became an empty acronym – they did not stand for anything. By then the purpose of the test was more modestly defined in terms of determining how well students analyze and solve problems – skills that are learned in school that will be needed in college.

The use of achievement tests which measure the level of understanding of the given curriculum is now widespread. These typically take the form of end of school examinations, the grades or marks from which one may determine university selection. These assessments are high-stakes because of the consequences for individuals. The French sociologist Pierre Bourdieu observed that "between the last person to pass and the first person to fail, the competitive examination creates differences of all or nothing that can last a lifetime" (1991, p. 120). In some countries, a single mark in the national examination can make the difference between a university place and a year in military service.

These are dramatic examples of how test results may affect a student's identity as a learner. However, the assessments conducted in education systems and in schools may have a pervasive impact of students' identities as learners. Assessments used to set or stream students into different ability groupings will impact on their identities as learners, especially when there is little movement between groupings. Research in mathematics groupings in England, where ability grouping has been encouraged by the government, has shown that of the children in a bottom group at 5 years old around nine out of ten will still be in the bottom group at 16 years of age and will no doubt see themselves as "no good at maths". Many high-performing countries, in which the gap between high- and low-achieving students is much smaller (for example Finland and South Korea), do not permit ability grouping in primary education.

Assessment and Identity: Some Positive Steps We Can Take

Any assessments which have high-stakes consequences will impact on an individual's identity.

How can we make this impact as positive as possible? Some of the ways we can do this are:

1. *Limit assessment ambitions by focusing on achievement.* Assessment is a social activity which informs us about what has been learned. It is not culture-free nor can it tell us about any underlying ability independent of what has been experienced and learned.
2. *Ensure the assessments are as fair as possible.* Fairness is about more than standardizing test-taking conditions. It involves reducing bias in the cultural assumptions about what is required and seeking to make sure students are clear about what will be assessed and have the resources to support this. If groups or individuals are disadvantaged in these processes, it will impact as their identity as learners in a particular culture. Where there are cultural or resource disparities, allowances can be made for this in terms of affirmative action?
3. *Interpret results more cautiously.* There has been a history, particularly in relation to intelligence testing, to infer more from assessment results than they can validly support. Using a one-off IQ score to pronounce on someone's lifelong ability to learn impacts powerfully on learner identity. Imagine never being allowed to drive because you failed your first driving test. This caution also applies to achievement tests when grades are interpreted without reference to factors affecting performance.
4. *Create sustainable assessment.* David Boud has developed the concept of the *double duty* of assessment in which "any assessment act must also contribute in some way to learning beyond the immediate task. . . assessment that meets the needs of the present and prepares students to meet their own future needs" (Boud 2002, pp. 8–9). In this way, assessment can help shape positive learner identities, equipping learners with confidence to face unknown futures.

In summary, assessment is a powerful social tool in the shaping of learner identities. The labels and judgments which assessments generate through scores and grades affect how we view

our ability, attainments, and potential. Their impact has often been negative, especially as tests can never fully capture what we know, understand, and can do. We live in testing times but we need not be at the mercy of them.

Assessment and Parents

Lois Ruth Harris¹ and Gavin T. L. Brown²

¹Central Queensland University, Rockhampton, Australia

²Faculty of Education and Social Work, The University of Auckland, Auckland, New Zealand

Synonyms

Caregivers; Classroom assessment; Evaluation; Examination; Families; Guardians; Testing

Introduction

Parents are important educational stakeholders, and their relationship with assessment is bi-directional in that they both influence their

child's results and are also influenced by those results. The term parent is used to refer to anyone fulfilling parental or guardian roles (i.e., caring for and making educational decisions on behalf of the child). Hence, in addition to or instead of a biological parent, this person could be a grandparent, step-parent, carer, foster parent, adoptive parent, other relative, guardian, or, in some cultures, a collective group of adults.

While parents do not generally have any direct say in how their child is assessed [although parent opinion does impact on assessment policy (Buckendahl 2016)], many parents actively interpret and use assessment data, whether to better understand their own child's progress or to form opinions about the quality of local schools. However, when investigating parent interpretations of such data, it is important to realize that the great majority of parents have very limited understandings of technical aspects of educational assessment, testing, and evaluation theory and statistics and instead draw on "intuitive test theory" (Braun and Mislevy 2005). Buckendahl (2016) argues that most adults are overconfident in their knowledge of assessment. Because most parents personally experienced assessment as students, they tend to overestimate their knowledge and understanding of such processes, even if reforms or advances in assessment have been introduced since they attended school. Most parents (and potentially many teachers) do not fully understand distinctions and limitations arising due to assessments' varied purposes (e.g., diagnostic, student accountability, school accountability), modes (e.g., informal observation, written assignment, standardized test), and scoring mechanisms (e.g., norm referenced, criteria referenced) (Nichols and Berliner 2007). As Braun and Mislevy (2005) point out:

Popular conceptions of how and why familiar tests work hold the same ontological status as impetus theory—dead wrong in the main, but close enough to guide everyday work in familiar settings. (pp. 491–492)

Braun and Mislevy (2005) argue that although many assumptions that nonexperts use to guide their interpretation of test or assessment data may be wrong, in low stake situations, minimal harm arises.

Intuitive Test Theory

However, parental misinterpretations are not always benign, making it important to address such incorrect understandings. For example, Braun and Mislevy (2005) identified nine common intuitive but incorrect misconceptions that nonexperts (like most parents) hold in relation to testing, most of which also apply to other forms of assessment as well. These include that:

1. An assessment measures what it says it does (e.g., a reading test measures reading rather than the student's familiarity with the test format, language proficiency, or only a narrow aspect of the domain, etc.).
2. Assessments with similar titles will tell you similar information about student achievement within a domain.
3. Scores are objective.
4. Assessments are more or less interchangeable (i.e., you could substitute one assessment for another and get essentially the same result).
5. Assessments should be scored by adding up points for each item and generating a percentage correct.
6. Traditional percentage correct cut points are appropriate measures of proficiency (i.e., an A = 90% correct, pass = 50% correct, etc.).
7. You can tell if a test item is good just by looking at it.
8. Multiple choice tests measure recall.
9. Multiple choice tests, standardized tests, and high-stakes tests are all synonymous.

Nonexperts, including most parents, often attribute far too much weight to an individual result and seldom acknowledge the presence of any form of measurement error. These assumptions help explain why parents are often reported as supporting "objective" forms of assessment like standardized testing and appear less concerned than teachers about student test anxiety and "over testing" (Brookhart 2013; Harris 2015).

Parents as Assessment Users

Neo-liberal management approaches around assessment clearly acknowledge parents as a stakeholder group entitled to assessment information. Parents are told about their child's assessment results via a range of reporting mechanisms which may include parent-teacher conferences, report cards (including narrative comments and/or grades), student work samples, informal conversations with the teacher, and student test scores. In most international jurisdictions, at least at specific grade levels, schools are required to report information in particular ways to parents in an effort to increase transparency and accurate communication of student progress (e.g., disclose scores for specific tests, report using letter grades, tie reporting to national standards). However, while there are often mandates or guidelines about how information is to be provided to parents, seldom is there any meaningful verification that parents actually understand the messages as intended (Timperley and Robinson 2004). This is potentially concerning given the intuitive assumptions that underlie many parent interpretations. Nor is there much consultation about what parents actually want to know regarding their child's progress and how that information could be best conveyed to them (Timperley and Robinson 2004).

Parents clearly have multiple uses for assessment data. Data can help parents understand how their child is progressing academically in relation to expectations. This is a major rationale for why parents seem to value the clear and "objective" data from standardized testing (Brookhart 2013; Buckendahl 2016), despite evidence that parents seldom understand the principles of test design sufficiently to interpret such data accurately or fully understand its limitations (Nichols and Berliner 2007). While norm referenced results may not shed much light on the student's specific strengths and weaknesses, parents may find it reassuring when their child compares well against their peers. Parents' personal experiences of and therefore familiarity with assessments they themselves took as students may also help explain their general preference for more traditional forms of assessment (e.g., exams, standardized tests,

essays). This means that the introduction of new or innovative assessment practices (e.g., portfolios, performance assessments, self- or peer assessments) may face resistance until parents are convinced such procedures produce valid results. Nevertheless, studies suggest that parents generally support new assessment practices if they can be educated to see that these assessments improve their child's learning and still meet their own data needs (Harris 2015).

It is vital that parents are able to accurately understand their child's progress so that they can act appropriately in response to assessment data. For example, they can provide extra homework support, enroll their child in outside tutoring, or purchase and use targeted learning resources at home. While teacher narrative comments may be more informative for parents wanting to support their child's learning, there is evidence that teachers often do not fully disclose problems with student performance to parents, particularly when students are in primary school and/or belong to minority or low socioeconomic groups (Timperley and Robinson 2004). Additionally, parents and teachers may have different understandings of what teacher grades, comments, and test scores actually mean (Timperley and Robinson 2004). Harris (2015) found that parents appeared far less concerned about potential negative impacts from standardized testing (e.g., student test anxiety, over testing) than teachers, perhaps because they viewed that the objective and "clear" information about how students performed was sufficiently valuable to compensate for any negative experiences the student might have.

The global rise of mandatory and publicly reported standardized testing has also introduced another major use parents in many jurisdictions may have for assessment data: selecting a school for their child. Parents may use publicly available assessment data to determine if a particular school is successful and therefore the kind of school they want for their child (Nichols and Berliner 2007). Parent interpretations of these data may be heavily influenced by media coverage that often misinterprets data or exaggerates the significance of score differences between schools (Buckendahl 2016).

Using assessment data rather than school reputation to inform school choice is relatively new. It can potentially “simplify” decisions for parents in that school test scores are easily compared; it is intuitively appropriate to choose the one with the highest test results. This, of course, ignores other important characteristics or services that schools have and which may be valuable to particular children. Within a school, choice can also be seen in parental decisions to request a new class or teacher for their child based on reports or tests.

Parent Impacts on Student Assessment Attitudes, Actions, and Outcomes

While demographic factors (e.g., socioeconomic status, ethnicity, language background) are correlated with student performance on assessments, parental expectations for their child’s achievement appear to be most influential (Davis-Kean 2005; Fan and Chen 2001). Student perceptions of their parents’ expectations and support impact upon their confidence, goal-orientation, and value for and interest in assessment tasks (Bong 2008). Studies suggest that while individual parent/child interactions around assessment differ, many students may be concerned about parent displeasure over poor results or hopeful of rewards or praise upon a successful performance (Bong 2008; Hall et al. 2004; Carless and Lam 2014; Peterson and Irving 2008). Parents may pressure their child to be successful on assessment tasks because they believe academic success will lead to a desirable career or other positive consequences, and this leads some to tightly monitor their child’s progress (Carless and Lam 2014). Parents may also reward or punish their child based on assessment results, using results to make decisions which impact on other aspects of the child’s life (e.g., taking privileges away from a child because of poor report card or test scores Brown and Harris 2016). Parents can also undermine student learning by completing take-home assessments for them or “overhelping” in an effort to improve the child’s academic results.

However, parental pressure does not appear to be equivalent across groups. For example,

students from high socioeconomic status schools report considerably more parental pressure than their low socioeconomic status peers (Peterson and Irving 2008) and children from some cultural groups (e.g., Confucian heritage backgrounds, Carless and Lam 2014) also appear to be under more pressure to perform. Consequences are also unlikely to be equivalent. For lower achievers, assessment data can reinforce potentially negative views of a child’s academic potential or abilities (e.g., “my child is not good at math,” “my child is not very smart,” “my child does not test well”). When these are shared with the child, they can potentially reduce the student’s self-image and efficacy as a learner.

Hence, there are likely to be significant differences in the ways parents discuss assessment and their expectations with their children, which are influenced by factors like culture, previous academic success, and socioeconomic status. However, across countries studies clearly indicate that when parents have unrealistic or overly high expectations, students tend to develop anxiety and/or negative emotions relating to assessment (Vogl and Pekrun 2016). Student actions around assessment are also clearly related to these conceptions and emotions. For example, conflict with parents around assessment results can encourage students to cheat (in an effort to artificially raise scores) or fail to seek help (to avoid looking incompetent) (Bong 2008). Hence, student assessment results can potentially impact upon relationships within their immediate and extended families and become a source of pride or shame.

Parent Impacts on Assessment Policy and Practice

While parents may have little direct say in how their child is assessed, they still collectively influence assessment policy and practice in multiple ways. Their needs and desires (or perceptions of these) often shape or are used to justify policy and practice, with policy makers often drawing on the common assumption that parents support standardized testing because they see it as objective and approve of comparative uses of such data

(Brookhart 2013; Buckendahl 2016). For example, educational authorities have often justified the public release of school assessment data in easily comparable forms (e.g., NAPLAN test results in Australia, formal league tables around Key Stage testing results in England, etc.) as being about transparency and accountability to stakeholders such as parents. Individual schools may also standardize assessment and reporting procedures to try to create consistency in reporting to parents.

However, while parents may seldom have any actual say in assessment practices, they can and do sometimes resist assessment reforms. For example, Sadler and Good (2006) reported an instance in the United States where the peer-grading assessments was legally banned in certain States after a parent instigated court case stemming from a child's experience of being bullied by peers during peer grading. Pockets of parent resistance to standardized testing, particularly when used as a school and teacher accountability mechanism, can also be seen in the growing "opt out" movements within the United States and others adopting such neoliberal approaches to accountability, with parents refusing to let their children participate in testing (Buckendahl 2016).

Conclusions

Parents, as carers of students, clearly both influence and use assessment. They may use assessment results to determine their own child's current or future academic achievement and potential or may draw on assessment data to inform school choice decisions. Their attitudes towards assessment and interpretations of their child's results can strongly influence their child's motivation and self-efficacy as a learner. Likewise, many assessment reforms are sold as being about creating better transparency and accountability to stakeholders like parents. While parents may not be able to directly dictate how their child is going to be assessed, they can and do resist some

reforms via legally challenging them or preventing their own child from participating.

What is clear is that parents are entitled to clear and accurate information about how their child is progressing academically. While it may be tempting for teachers to hide or downplay student academic weaknesses in an effort to protect student well-being, this is unlikely to be beneficial for students in the longer term as it may prevent parents from providing or seeking the additional help the student needs. It can cause considerable tension within the family and between families and schools if poor results on high-stakes assessments (e.g., a high school graduation test) arise without adequate warning. More work is clearly needed to better understand how parent interpretations of assessment grades may differ from those intended by teachers in order to ensure alignment and partnership between parents and teachers around the educational outcomes for each child.

It is also important to continue to debunk interpretations of assessment based on the intuitive assumptions most nonexpert parents would draw on when making sense of results. While parents clearly deserve access to data about the performance of their child's school, providing test data as the main indicator of school success is likely to be problematic. There is serious risk that test data will be misinterpreted (e.g., small differences in scores would be considered evidence of superior/inferior performance rather than chance). Unfortunately, as Mansell (2013) identifies, discussions about assessment results within the media are seldom helpful in correcting such misinterpretations as they tend to report data in ways which are sensationalized and/or politically charged. Hence, if public reporting of such scores is to continue, it is important that teachers and members of the psychometric community increase their efforts in supporting parents to accurately interpret data so that valid conclusions are drawn (Buckendahl 2016). This means that teachers need to develop good ways to communicate assessment limitations in language that diverse

groups of parents can understand. Assessment experts also need to work with the media to encourage accurate and thoughtful rather than sensationalized coverage of assessment data.

Parent views on assessment clearly matter because they influence national, State, and school level policy and practice as well the attitudes and efforts of their own children. Parents' own data needs must be carefully considered by classroom teachers, educational policy makers, and test designers, particularly those with responsibilities around the design of reporting mechanisms. Those responsible for designing assessments and reporting them to parents must be sure that parents understand clearly (a) the assessment mode, (b) the assessment purpose, and (c) how results can be validly interpreted. Careful work in this area will help parental interpretations of data to be based on robust grounds rather than on simplistic intuitions about assessments.

B

Bachelard and Philosophy of Education

James D. Marshall
The University of Auckland, Auckland,
New Zealand

Gaston Bachelard was born on 27 June 1884 at Bar-sur-Aube, Champagne, where his parents owned a small paper and tobacconist shop. He received his secondary education in Bar-sur-Aube and served in the First World War (including 38 months in the trenches and the award of Le Croix de Guerre). Essentially, he was an outsider to the academy, for he had taught himself chemistry while working as a postman, before teaching in secondary colleges at Bar-sur-Aube. Studying slowly he was awarded his doctorate from the Sorbonne in 1927. It is clear that the achievements in particle physics had both excited and influenced him. He was to say: “one decade in our epoch is equal to centuries in earlier epochs” (quoted in Lecourt 1975, p. 33). Having turned to philosophy of science, he was to teach for 10 years in the Faculté des Lettres de Dijon before becoming a Professor at the Sorbonne in 1940. In May 1960 he was made an Officier de la Légion d’Honneur and, dying on 16 October 1962, he was to be interred at his Bar-sur-Aube on 19 October.

Bachelard was recognized as both a philosopher and poet, but it is only his work as a philosopher which will be considered here. He is

important not only for his work in the area of philosophy of science but also for his influence upon a number of French philosophers. Jean Cavaillès, shot as a member of the Resistance to the German occupation in WWII, was an influence upon Bachelard and upon this French stream of philosophy. Within his general philosophy, this entry will concentrate on those features which were to later influence French poststructuralism.

Bachelard’s anti-positivist philosophy of science was developed in a number of texts between 1927 and 1953, anticipating some of the conclusions of Thomas Kuhn, though he was not to exert any direct influence on Anglo-Saxon philosophy of science. For Bachelard science was an autonomous activity, dependent only upon itself for its norms and practices – in spite of the intrusions of philosophers. His work involved a constant polemic against philosophers because, according to him, philosophy wanted to cover up, hide, and occlude “the real historical conditions of the production of scientific knowledges” (Lecourt 1975, p. 27). Indeed the idea that the history of science could be a fruitful source, even a source, for logical analyses was quite alien to analytic philosophy of science (Tiles 1984, p. 3). Also he believed that physical theories were not divorced from metaphysical commitments, though they might claim to be so. Bachelard then uncovers the “unthought” of philosophical discourse about science in a “recovering,” which also opens up the notions of the “unconscious” and the “unthought” and the further possibility of the “recovery” of

these by a “psychoanalysis of reason.” (Traces of this notion of a “psychoanalysis of reason” are to be found in the early work of Michel Foucault.)

But Bachelard’s scientific reputation depends also, in part, upon his studies of poetic language, day-dreaming, and phenomenology, and their application to episodes in the history of science. Thus poetic imagination, as involving an affective engagement with “things,” was seen by him as a condition of scientific productivity. But this insight is not hived off into the deflated notion of a “logic of discovery” as in the philosophy of Sir Karl Popper, for Bachelard include it in his philosophy of science. Thus Kuhn’s important *Structure of Scientific Revolutions* (1962) may have been an “old hat” for French philosophers of science.

According to Gary Gutting (1989), the account of scientific change and, accordingly, scientific progress was the focus of Bachelard’s philosophy of science. Bachelard held that reason was best exemplified in science and this was best understood, not by studying science now, but by studying its history (in philosophy of education, on the importance of the history of science, see here the Althusserian-inspired work of Michael Matthews). Reason was best discovered in science by discovering how reason was used in practice, in addressing particular problems (cf. John Dewey [1938] *The Logic of Inquiry*), as opposed to studying abstract theories. The history of science showed, he argued, how abstract philosophical and metaphysical theories in science were gradually overturned through the practical work of scientists.

Bachelard found discontinuities in the history and development of science that were not, in principle, capable of logical reconstruction, prior to Kuhn, with whose work there are some similarities. But whereas Kuhn was concerned with theories, or paradigms, Bachelard’s concern is with concepts. The key concept here for Bachelard is that of rupture, which has four epistemological aspects or categories. These he terms breaks, obstacles, profiles, and acts (Gutting 1989).

Breaks are concerned with (i) how science breaks away from common sense in formulating its concepts (see also Stephan Körner [1966] *Experience and Theory*; an essay in the philosophy of science) and with (ii) breaks between scientific concepts. An example of (i) would be the shift from common sense notions of intelligence to IQ conceived as intelligence, whereas an example of (ii) would be the changes that have occurred historically in the scientific concepts of the atom. Breaks, in turn, are opposed by obstacles, which can be construed as residues from earlier concepts which, especially if they were important in the past, tend to block changes to new concepts. Here common sense may be a major obstacle, operating as it does as an implicit assumption of the way the world is. If they operate at an implicit level, then Bachelard was to propose a set of techniques to bring these assumptions to the “surface.”

An epistemological profile is an analysis of a given person’s understanding of a particular scientific concept. This analysis would show where an individual stood in relation to the historical development of a concept or theory and the extent to which residues were retained or breaks maximized. In recent liberal political philosophy, a profile would show whether a person was a liberal or neoliberal according to how underlying concepts such as individualism, freedom, and equality were conceived. Residues are countered by breaks but this requires on behalf of the scientist the Bachelardian notion of an act. Acts are leaps but not just a leap in any old direction at all, but one in the direction of progress.

Cavaillès and Bachelard rejected the idea that scientific progress was to be determined by collating in a jigsaw type pattern the established truths of science. For Bachelard, from his work on the imagination and reverie, epistemological acts which produced these breaks were guided not by normal science but by poetry and art. (See also the philosophical work of distinguished biochemist Sir Peter Medawar [1966], *Induction and Intuition in Scientific Thought*.) Foucault was to

declare concerning Bachelard in 1954: “no one has better understood the dynamic work of the imagination.” Indeed Foucault’s early work on Binswanger (also a Bachelardian) cites Bachelard against Sartre on the topic of the imagination. Bachelard, in turn, was very complimentary to Foucault on his *Folie et Deraison*.

For Bachelard scientific progress depends therefore upon epistemological breaks. According to him, these breaks were quite distinctive – e.g., the break from Newtonian to Einsteinian physics was seen as very distinctive. Science therefore cannot be seen as progressing linearly or necessarily rationally (cf. Kuhn). But progress is conceived and measured from the present status of science, and history of science will provide a history of rationality. But this notion of progress is questionable, because Bachelard accepts that the science of the present is not only an advance (as opposed to a mere change), but that the science of the present should be invoked to both understand and assess the achievements of past science. This modern assessment is to be based then upon how past scientific endeavors contribute to the “developed” science of the present. What is sought are the effects of the past upon the present. There are of course some questions which historians would raise about the appropriateness of such moves for doing history: for example, Philippe Ariès’ *Centuries of Childhood* (1962) was criticized for his projection of a twentieth century concept of childhood backward to medieval times.

Canguilhem is to temper Bachelard’s concept of the (distinctive) epistemological break, and the influence upon Foucault is more general than specific.

The implications for education from Bachelard’s work include at least: the account of rationality, the importance of teaching the history of science and not merely science as it is now, the implications for those research methodologies which appeal to “a” philosophy of science, the importance of the imagination (in his sense) for rational thought, and the notion of conceptual discontinuity in scientific thought.

Beauvoir and Philosophy of Education

James D. Marshall
The University of Auckland, Auckland,
New Zealand

Simone de Beauvoir (1908–1986) had been almost totally excluded from the philosophical canon until the 1980s, when a revival and reinterpretation of her work by mainly feminist philosophers began. For example, she is not mentioned in Walter Kaufmann’s *Existentialism from Dostoevsky to Sartre* (1956) (nor is Maurice Merleau-Ponty, though Albert Camus* is

mentioned). In Paul Edwards' comprehensive philosophical encyclopedia, *The Encyclopedia of Philosophy* (1967), the only mention is of her *Ethics of Ambiguity* (1948), which is said to be important in its own right but in relation to Jean Paul Sartre. Yet there is no further amplification or discussion in that source of what is said to be an important work and how it was related to Sartre – a crucial issue. In general her putative philosophical works are subsumed under or said to be derivative from those of Sartre, or they are recorded as “a kind of footnote to Sartre” (Kruks 1990, p. 84). In Christina Howells' (1995) *The Cambridge Companion to Sartre*, she is mentioned once only and that for providing biographical material on Sartre's reading of Husserl. Hazel Barnes, however, is a major and early exception: “De Beauvoir is more than Sartre's interpreter” (1959, p. 4). She is also more than a novelist. For biographical details see Claude Francis and Simone Gontier (1989) and Deidre Bair (1990).

It would seem that until her death in 1986, Beauvoir aided and abetted in this general interpretation and in a number of sources. Some feminists maintain that she created a myth about her own philosophical contributions to existentialism (for papers on this see the edited collection of Simons 1995). But this received position on the interpretation of her philosophical work was not reopened until the publication posthumously, by her adopted daughter Sylvie le Bon de Beauvoir in 1990, of her *Letters to Sartre*. Possibly it needed the publication of these letters to question the received position.

The issue as to whether or not she was an original philosopher seems to hinge upon whether she had identified and articulated certain key ideas which Sartre was later to present as his, especially in the opening pages of *Being and Nothingness* (1943), or whether she merely contributed to Sartre's ideas and work. Arguably this is the case on the notion of the self. This issue can be pursued initially by a careful reading of her letters to Sartre and their war diaries during the period between October 1939 and January 1941, when she was writing *L'Invitée* (translated as *She Came to Stay*). This, her first published novel, was completed in 1941 but not published until 1943. What must also

be considered is the philosophical import of the first three chapters, especially the first eight pages of *She Came to Stay*. Her second novel *Le Sang des Autres* (*The Blood of Others*) is also important here. She should be considered in her own right, not as an appendage to Sartre. We will therefore look at some of the philosophical ideas in her early novels – particularly the notions of Self and Other and freedom – and her approach to doing philosophy.

Beauvoir did not write academic philosophy. She had passed her aggregation and commenced teaching in lycées in 1929 (Latin initially and then literature, but philosophy by 1932 (Bair 1990, p. 180)), but as early as age 18, she had begun to write fiction. Some of this early fiction was to be published later (Beauvoir 1968, 1982). Unlike Sartre, whose philosophical works (though not his philosophical novels and plays) were written abstractly and who was seeking a grand totalizing philosophical system, Beauvoir did not want to write so as to present philosophical ideas in either an abstract manner or as divorced from actual or possible human experience. For her, literature presented and provided a way of relating philosophical ideas to experience (cf. Camus), particularly as it presented a way of expressing her own experiences as part of a general philosophical framework. Her novels can be seen as metaphysical novels, as presenting a fictional narrative in which her own experience is drawn heavily upon, but through a philosophical or metaphysical grill (see further, Pilardi 1999).

There can be little doubt that she did not abandon her philosophical background and grounding, for she even extended it – for example, she notes her “discovery” and extended reading of Hegel in 1940 in her letters to Sartre (e.g., 13, 14, 16, 19, 24, 29 July; 29 October) to whom she would explain Hegel in return for him reminding her of Husserl (13 July). The frontispiece of *She Came to Stay* features a quotation from Hegel (“Each consciousness pursues the death of the other.”), and she uses some of his ideas in *The Second Sex*, first published in 1949 (e.g., part I). However she expresses early doubts on Hegel, for by 8 January 1941, he “no longer consoles me,” though she begins to teach his ideas (23 January). But without

Sartre to talk to on such issues as Hegel, she says (ibid): “If I were condemned for long never to talk, I’d end up writing philosophy, from the need to express myself.” So doing philosophy was still important at a time when *She Came to Stay* was completed; philosophy in an oral dialogue was acceptable but writing it – as academic philosophy – was for her a last resort. Writing it in some other form, however, was far from being a last resort. For Beauvoir this meant insight into her own life. As Hazel Barnes says of *She Came to Stay* (1959, p. 122):

...the analysis of human relationships and personalities is more philosophical than psychological. Perhaps de Beauvoir and her fictional counterpart [Françoise] are accustomed to think in this way about themselves and their reactions, but most people are not as metaphysically acute.

Beauvoir believed then that human experience and problems of personal life should be presented to exemplify, or to show, philosophical ideas. Although she features or appears at points in her own novels, as do her close friends, confidants and lovers, her narrative is not presented from one personal viewpoint. The experiences and personal views of the major characters are seen also from each of their viewpoints. In *She Came to Stay* while her personal experiences form part of the viewpoint of Françoise (Beauvoir), she is not necessarily writing the novel from one personal viewpoint, for the viewpoint of each of the main characters is presented in the first person. In *The Blood of Others*, however, while all of the viewpoints of the main characters are presented, only the viewpoint of the main character, Jean Blomart, is presented in the first person, and this was probably for stylistic reasons. Nevertheless in both novels the viewpoints of the Others are necessary for each character to be a self or subject. The philosophical point is that the Other is necessary for the constitution of the self or subject.

Beauvoir is to reject the notion of a solipsistic isolated self. Writing just prior to the outbreak of WWII, she says:

Little by little I had abandoned the quasi-solipsism and illusionary autonomy I cherished as a girl of twenty; though I had come to recognise the fact of other people’s existence, it was still my individual

relationships with separate people that mattered most to me, and I still yearned fiercely for freedom. Then suddenly, History burst over me, and I dissolved into fragments. I woke to find myself scattered over the four corners of the globe, linked by every nerve in me to each and every other individual. (Beauvoir 1965, p. 369)

In *She Came to Stay*, the body is not a mere object or thing but always experienced reality – “my heart is beating; I am here.” Elsewhere and some years later, she is to say explicitly: “It is not the body-object described by biologists that actually exists but the body as lived in by the subject” (Beauvoir 1989, p. 38). So a human being exists not merely in a body as an object but as a body subject to human institutions and constraints so that the subject is both conscious of itself as a subject and obtains fulfillment. For her one can never be a mere biological body as there is always a dimension of meaning. Thus:

...we must view the facts of biology in the light of an ontological, economic, social and psychological context...there is no true living reality except as manifested by the conscious individual through activities and in the bosom of society. (Beauvoir 1989, p. 36 f.)

In a nightclub scene in *She Came to Stay*, she explores various possibilities for “experiencing” the body. First we can identify the notion of consciousness of the body as lived in by the subject when Xaviere does things to her arm and, while touching her eyelashes, talks to herself. Then there is the body of a young woman in feathers as perceived by her male companion who has pounced on her hand, i.e., the body as an object for the other subject. Her body is perceived by the other, the man, but she rejects this “objectification” of her body as being part of her experience of her body because it becomes a thing. And a young woman talking about flirting is perceiving the body of the man – she is staring at him – but at the same time rejecting the notion of her body as potential object for the other subjectivity. This is again the body as object for a subject. Now the reality of the subject’s lived experience must include both the experience of the lived body as part of one’s own subjectivity and the experience of the lived body as object of another subjectivity.

To dissociate or to deny this dual aspect of experience was to be in bad faith for Beauvoir. (Sartre is later to use the girl in the feather example as an illustration of bad faith, unacknowledged, in *Being and Nothingness*.)

The ideal coordination for the exemplification of good faith would take place when there was an identity between the two subjectivities – the body as lived in and as part of one's own subjectivity and the body as an object belonging to another subjectivity. The young woman in feathers presents an example of a severe disjunction between the two subjectivities. For Beauvoir the self is a fusion of mind and body and consciousness is prereflective and intentional, directed to objects in the external world, including her body. But this consciousness does not require talk between subjects. The subject is aware of the other body as object and is aware from the look of the other that her or his body is an object of the other subject. The social Other sees both subjectivity and objectivity in the other as a reciprocal relationship. This is not the Other as alienated from the self as in the early Sartre.

In *The Blood of Others*, Beauvoir develops similar themes on the self, but the situation of this novel is heightened because of the involvement of the main characters in the resistance. Beauvoir was disappointed that this, her second published novel, was to be interpreted as a resistance novel. In other words, from my reading, the philosophical content on the self and the other was not seen as important. This is a metaphysical novel but one which progresses from her first novel because the notion of identity must now include some political commitment which is not merely intellectual and inert, for there must be some active participation in accordance with that intellectual commitment.

At the end of the novel, Hélène, the lover of Jean Blomart, is dying from wounds suffered in a resistance attack upon the German forces occupying Paris. As Jean sits with her in almost total silence as she is dying, he not only recognizes his love for her but also recognizes from her, and in her silence, that in order to establish his own identity, he must commit himself to the next planned resistance operation, that is, that he must

abandon forever his own intellectual but non-participatory stance toward political matters, held because of a fatal accident caused to a friend in an earlier demonstration. In realizing that her approbation of him is so important for his own identity and for her identity too, as he recognizes both his love for her and what he has to become, Jean defines himself as both politically committed and actively involved in the resistance, even though the activities of the resistance will lead to pointless reprisals upon innocent French people. To a certain extent this represents existentialist angst, and to that extent the novel can be seen as both existentialist and philosophical. But any such restricted reading ignores the metaphysical aspects in this novel which impinge upon the definition of the self and the other.

Was it Beauvoir then who had laid out some of the crucial philosophical concepts of "Sartrean" existentialism by at least 1940, for it is in the first opening pages of her first novel that her own philosophical ideas are to be found and outlined? And these ideas are repeated and further developed in her second novel, *The Blood of Others*, and they continue into *The Mandarins* and *All Men are Mortal*. No doubt it can be countered that it was Sartre's ideas that were developed, for they had collaborated for several years by then, and Sartre had read and commented upon the drafts of her manuscript. And they were discussing Sartre's philosophical ideas (e.g., *The Prime of Life*; Beauvoir 1965, p. 434). In any case it might be argued that what Beauvoir was later to develop in *The Second Sex* was a notion of the gendered self.

This issue needs further and fuller elaboration (but see, Fullbrook and Fullbrook 1993; Simons 1995).

Introduction

Today increasingly pluralistic and heterogenous societies, as well as a growing awareness of children as inheritors of the earth, challenge the understanding of which pedagogical and curricular frameworks in early childhood education best meet children's interests. Experiences in the 'here-and-now' and those that are anticipated for future generations stimulate the need for new (and perhaps a return to 'old') negotiations about the content and purpose of education. As our title suggests, the German concept of *bildung* holds

great potential for early childhood education today when contemplated as a serious part of these negotiations. Indeed, *bildung* (and its various associated contemporary cultural meanings across Nordic and Australasian ECE communities) promises to resurrect attention towards the ‘good life’ for young learners in curriculum.

This entry will first summon notions of *bildung* from its Greek and German origins before contemplating its related conceptualization across other world zones. The broad concept of *bildung* orients towards a broad consideration of education. Rather than viewing learning as a means of enculturation, assimilation or, worse, indoctrination, learning connected to *bildung* is seen in terms of its potential to enhance human experience. *Bildung* outlines a history of negotiating pedagogical ideals including the humanizing nature of education, character building for responsible living and democratic participation. *Bildung* involves cultural practices, views on children’s position and their relations to families, to societies and nature and is saturated with meanings that have developed over decades and continents. In this conceptualisation views, ideology, ideas and ideals are shared at the negotiating table and may cause confusion, contradiction and dispute rather than synthesis. Here primacy is given to multi-voiced events which orient the emergence of a dialogic framework in early years’ curriculum. The article concludes by outlining the contemporary case for the centrality of dialogues as curriculum when *bildung* returns to the fore.

The Origins of *Bildung* in Education

As a concept, *bildung* is deeply rooted in European pedagogical thinking from Greek Antiquity, but over the last three hundred centuries has emerged as a key element in the broader development of Western culture and democratic societies. This renewed interest has led to a reorientation toward education as a social and cultural process through which understanding may emerge. Much of *bildung*’s recent application draws its source from German philosophy in particular. The concept historian Reinhart Koselleck (2007, p. 17)

divides this history in three ages: one theological, one pedagogical enlightened, and one modern age that is mainly self-reflexive; the latter will later be elaborated.

Bildung has no obvious English corresponding translation, although the concept of *edification* and *shaping* or *formation* have been proposed. While *edification* is associated with spiritual *bildung*, the latter are used as translations connected to a detachment from the theological understanding. Shaping or formation opens for a more reflexive understanding of what *bildung* should be directed to. The word itself derives from Latin word *formatio*, which means *shaping* or *formation* or in German *bildung*. *Bildung* contains “*bild*” that means *image*. In early historical traces, the concept signifies a process of rebuilding the image of God in humankind.

In the age of enlightenment, the relation to religion changed, and God was seen merely as the creator of nature; humans were left to realize human potentials. *Bildung* was now understood as development of man’s natural abilities, as an education of the inner states. The idea that *bildung* existed in as the split between the individual and humanity at large can be traced to von Humboldt’s scholarship (Løvlie 2003, p. 152). Influenced by Hegel, Von Humboldt’s *bildung* heralded a movement toward higher levels of thought as a dialectic between self and culture. As Brandist (2016) explains, this view led to an educational-institutional interpretation of *bildung* as transcendence into deeper inquiry and understanding.

The German *bildung* tradition(s) can also be traced as an emphasis on relational and generational aspects opposing enculturation and upbringing in the sense of conforming or obeying the older generation. Attitudes were here seen as being shaped through children’s own activities based on the view that the older generation cannot produce or secure good attitudes or habits and may even violate children’s freedom through such intervention. The formation of attitudes in children was seen as possible by processes of awakening and care. Ideas from Friedrich Fröbel, for instance, can be identified along with this view. *Bildung* is here connected to the individual child belonging to an affirmative relationship with

generations and communities. Fröbel's ideas built on the philosophies of both Comenius and Pestalozzi who introduced child-oriented learning to the educational process.

In Germany today, *bildung* is commonly used in two central ways. While the concept is often summoned to talk about education as the acquisition of certain skills and competences, it is also viewed as a means of fostering democratic citizens, or "allgemeine *bildung*." A historical perspective illuminates this distinction – for while the older generation could teach children by transmitting certain educational methods and techniques, the skills needed to live a "good life" in a community, attitudes, and beliefs could not be so easily taught. In this conceptualization, education was directed toward specific tasks and abilities to master, while *bildung* was seen as engagements that were connected to the inner drive and attitudes, in other words, who the person *is* as a subjective participant in a social community. Education to a certain occupation and profession was seen as secondary to education for humanity, or what we now might call *bildung*.

The concept of *bildung* can therefore be broadly described as both the *process* (*bildung* as a verb) as well as the *result* of learning (*bildung* as gained by education). To gain *bildung* as a result of formal (school and universities) or informal education (movements and nongovernmental organizations) raises important questions concerning what was worth learning and for whom.

Contemporary Notions of *Bildung* in Education

Learning is considered the base of education and as a human condition. Every child is a learner by nature. Exactly what a child will learn through education is however difficult to control and therefore uncertain, because it is conditioned by a wide range of social, structural, and individual dynamics. Institutionalized goals of learning will contain formulated outcomes for the individual or goals for groups to strive for. Whether learning is seen as an individual or social process, learning still implies a process where what is learnt belongs

to a futures' state. The teacher as a representative for an older generation is responsible toward the child as representative for the younger generation. Children are today worldwide by laws and regulations considered to be a person of their own rights. Contemporary education is therefore faced with a Kantian paradox – how to use a legitimate power to regulate, organize, and teach a content where freedom and responsibility (democratic citizen as participant and contributor) are large goals for education, in other words, *how to cultivate freedom by force*.

This question was taken up by John Dewey (1916) who summoned *bildung* to argue that learning and experience are two sides to the coin. In making this claim, he started an important discussion that brought the learner and the subject into dialogue with one another. Dewey's pragmatic and democratic approach to education emphasized learning on the basis of needs and interests of the child (exploring, experimentation, and "trying on") as opposed to an exclusive focus on the state. Learning was not seen as the work of something ready-made called to mind, rather than the mind itself is an organization of original capacities (Dewey 1916, p. 315). Dewey's attention to *bildung* is evident here – as an individual passes from one situation to another, the world and environment expand or contract. This is a lifelong and transformative process.

Educational institutions are implicated in this revised view of *bildung*. Not only are they nationally and transnationally regulated with curricula that are negotiated in many levels, but they are also locally oriented. Education is thus always situated within the certain individuals present: local authorities, teachers, children, and families. While the curriculum will be of a general character and expectations will be that every child is entitled to knowledge, skills, and processes of *bildung* stated in the curriculum, there is however a problem connected to given guarantees about that every child will learn what is expected. Many efforts to control what goes on in schools and early-years institutions have been made: disciplining, rules of order and behavior, segregating children with learning impairment, and individualized education and testing, to name some. The further

paradox arising here is the risk of producing children that fail according to certain criteria, completely in contradiction to the intentions of education. *Bildung* as an aspect of education and also opposed to the belief of education as controlling to enhance learning will emphasize learning for life as important as learning for occupation.

Central to this institutionally oriented interpretation of *bildung* is the role of “language as world-view” (Brandist 2016). Here, education is seen as a key engagement with multiple meanings through which the individual can become more aware of their own and other subjectivities. Neo-Kantian Paul Natorp (1920, cited in Brandist 2016) advanced this agenda in his notion of social pedagogy which set out to interpret education as a social condition that could be studied through the limits of reason. An associated phenomenological engagement is taken up by Russian philosopher Mikhail Bakhtin in his notion of heteroglossia (*raznorechie*) as a series of languages that orient the world but, in this case, turn toward the process of meaning-making rather than outcome or “truth.” Bakhtin’s 1930s essay *Bildungsroman* further explicates his ideas on *bildung* by drawing on Goethe’s famous novel – Wilhelm Meister – which mapped out an agenda for contemplating the transcendent individual within narrative. By positioning the “hero” as a character embroiled in a lifelong process of “becoming,” Goethe set in place dimensions of time in space, past, present, and future as central considerations of the human experience. Now, engagement was not considered merely as a multiplicitous language event but also an event that is located within a certain chronotopic space, with associated axiologic undercurrents and implications (White 2013).

Despite the emergence of Goethe’s *Bildungsroman* novel in the 1930s and Dewey’s parallel considerations for education, the influence of *bildung* was not fully felt in European educational discourse until the 1960s. As more dominant psychological and sociological notions like qualification, socialization, and learning took precedence, critical thinkers such as the ones belonging to the

Frankfurter school (e.g., Adorno, Benjamin, and later Wolfgang Klafki) turned to *bildung* because they saw the liberal and emancipatory potential for this concept to generate a critical potential and resistance of standards. In other parts of the world, *bildung*-related notions of emergence (e.g., *obrazovanie*, *danning*) resided within ideologies that were not (and arguably are still not) widely known to the West.

According to Biesta, a renewed interest in *bildung* did not fully emerge in school discourse in the 1980s as a result of globalization of economy and the increase of migration and mobility. Plurality was, to a large extent, seen as a problem, and in this climate, there was a tendency to look for uniting forces, as general education. The idea was to overcome differences through “universal” or “general” education, what some might call colonization. In many countries, you could see detailed national school curricula, which, according to Biesta, often revealed a narrow-minded instrumental and centralist conception of education (Biesta 2003, p. 63). *Bildung* was here signifying curricula with canons and detailed lists of what every citizen needed to know in order to be considered educated. Ideas coming from critical sociology of knowledge revisited Herbert Spencers’ question, *whose knowledge is of most worth?* Critical pedagogy took up the concept and idea of *bildung* for a redefinition where *bildung* is not merely an introduction into the existing culture, but includes the force and ability to disclose the conditions for power and for knowledge. School knowledge was in this discourse not necessarily the true knowledge, rather a certain perspective as the knowledge of value for the able, for the male gender, for the person born white, or for the upper classes.

When knowledge was made a social construction, a space was left even more open for the individual for taking agency in the formation of the self. Corresponding to the change of the view of the child, seen in many Western countries after the Second World War, was the change from a view of the child as belonging to a family who defined what was of the child’s best interest,

toward a view of the child where the child was seen also as a subject with its own rights, opinions, and as a future resource for societies. Furthermore, when the world was seen as a plurality of local practices that became interconnected, by roads, railway media, and ICT, we see that some practices were transforming by taking in elements from the world outside and blending them with existing practices. What then is considered general or universal is nothing more than an extension of historically local practices. *Bildung* is now not only a rational ability to form oneself as an individual; however, *bildung* must be considered a process where the subject operates in a field of knowledge and power constellations. To put it in Foucault's term, the subject cannot combat power by knowledge, but only uses the knowledge to take on another perspective. *Bildung* is now seen as the conditions for the individual to act, be, do, and think; *bildung* is the self-formation processes that go on within certain conditions and mechanisms.

Despite its promise, *bildung* is seldom summoned to contemporary educational discourse in general – even today. This may be partly attributed to the naivety of its neo-Kantian proponents who, as Brandist (2016) points out, failed to appreciate the relationship between “academic life and the production of scientific knowledge” (p. 10) and, in doing so, underestimated the importance of power and propaganda. To entertain the thought that a person is free to “become” (in the spirit of *bildung*), according to this view, fails to appreciate external influences that far exceed the individual learner. For this reason, *bildung* may be unsatisfying for educational academics who seek greater complexity in a world characterized by power and control. Yet, despite this naive optimism, *bildung* signals a profoundly hopeful agenda for learners. It offers a different kind of promise to the educational field, one that entails classical problems in the education of (wo)man and critical understandings for a specific time in history. Moreover, *bildung* offers scope for contemplating learning far beyond the dominant “educative” domain of contemporary schoolification because

its orientation lies in human agency. Perhaps, for this reason alone, *bildung* has taken root in early years' curriculum over recent years, where emphasis is placed on the potential of learners as they engage with and within the world. This phenomenon will now be briefly addressed as contemporary treatment of *bildung*-related concepts in Norwegian and Australasian early childhood education (ECE) curriculum contexts.

***Bildung* in the Norwegian ECE Context**

“Danning” is the Norwegian concept of *bildung*. The concept of “danning” is first seen in the Norwegian Kindergarten Framework from 2006, where it was given a dominant place in the first paragraph of the Kindergarten Act. In the revised Framework from 2011, the concept was developed. It is worth noticing that the official translation of “danning” is not *bildung*, rather *formation* as seen in the following quote from the English version (Ministry of Education and Research 2011[2012]): *The Kindergarten shall, in collaboration and close understanding with the home, safeguard the children's need for care and play, and promote learning and formation as a basis for an all-round development.*

There were two main reasons for including the concept “danning” in the national kindergarten framework. First, “danning” was considered broader than the present omitted key concept “upbringing.” Second, “danning” as a verb was considered more attuned to the child. This was aligned to the understanding of “danning” as “selvdanning” (self-*bildung*), and therefore, “danning” was seen as promising for the future of educating the child in a kindergarten context.

In the Norwegian discourse, there is a distinction between “danning” as a verb signifying a continuous process and “dannelse” signifying the result, often associated with classical intellectual or artistic exclusive knowledge, skills, and behavior and by some associated to classical *bildung*. “Danning” opposes the structure of

power lying explicitly in the teachers' domain as in the concept of "upbringing," to lift/raise a child into the standards of what is considered well-behaved, accepted, and defined by the majority or by educated groups. The Sami people, specifically, embraced the concept of "danning" for these reasons. "Danning" in the verbal form signifies both an individual and social formative process and how human subjectivity is dialogically shaped in a web of relational, cultural, and structural conditions.

Concepts of Belonging and Becoming in Australasian Discourse

In both New Zealand (Ministry of Education 1996) and Australia (Australian Government Department of Education, Employment & Workplace 2009) curricula, *bildung* is not explicitly mentioned either. However, it is hinted at strongly in the positioning of concepts such as "Belonging" and "Becoming" which describe learning as a means of "shaping who children are and who they will become" and "learning to participate fully and actively in society" (ibid, p. 7). The NZ ECE curriculum is less explicit about these concepts, describing belonging as one of five curriculum strands as a means to "build opportunities for social interaction with adults and other children. . ." (Ministry of Education 1996, p. 54), but attempts to integrate these principles within the holistic framework that is promoted. Brostrom (2013), summoning Klafki's "category *Bildung*" (p. 253), suggests that integrating personal experience with objective reality provides a better means of expanding curriculum beyond the *form* of learning (i.e., the activity which is granted prominence) toward its *substance* (i.e., its significance and utility to the learner). Taking this more interdisciplinary approach is well evidenced in the Australian curriculum where "Being, belonging and becoming" are broadly construed as ways of being that are oriented toward "the building of more socially just society" rather than discrete outcomes or goals (Sumsion and Wong 2011, p. 39). Yet it is clear that the central emphasis of

Te Whāriki also strives toward such holistic principles – often in the wake of neoliberal pressures to do otherwise. Attention toward such qualities and characteristics are best evidenced in indigenous Maori depictions of a holistic program which caters for "the mind, spirit and soul of the child. . . motivate[ing] a yearning and passion to learn" (Walker 2008).

Bildung in the Early Years

Notwithstanding the considerable challenges for curriculum construction in foregrounding *bildung*-related notions of learning within contemporary education, the concepts of both "danning" and "belonging" (as expressed in contemporary Norwegian and Australasian ECE curriculum frameworks) share many of the same educational values for learning. In common, they signify how children and teachers are closely interrelated as human beings in natural, urban, and rural landscapes and cultures, as well as with material, cognitive, and ideological artifacts and that this interrelatedness operates in a flux. While *bildung* could be understood as series of subjective processes that sophisticate the individual as a participant in society, one could also frame "danning" and "belonging" as a process where subjects are simultaneously shaped by a web of cultural and structural conditions and in turn shape the world by agency.

These depictions of curriculum strongly align with Brandist's (2016) explanation of the relationship between *bildung* and belonging by summoning Bakhtin's (2012) (re)interpretation of discourse in the novel. Here, Bakhtin suggests that engagement with other subjectivities (in his conception with other "classes" p. 70) is important to an individual or group in understanding their own becoming. By this he meant that interactions with other ways of speaking (and thus thinking) about the world have the potential to open up greater possibilities for awareness in a broader sense that might otherwise be attainable. Such a view is wholeheartedly consistent with notions of *bildung* yet poses challenges for the appropriate

realization of these related concepts when posed as a desirable curriculum goal or outcome. Since *bildung* is fundamentally concerned with formation, emphasizing the endpoint is less desirable than lingering in the educational experience – a challenge for teachers and policymakers alike. It is evident that this challenge has been wholeheartedly embraced by both Norwegian and Australasian ECE communities.

This view implies that every pedagogical event will be conditioned by a range of more or fewer dynamic aspects which shape the lifelong learner. This conception implicates both children and teachers who are simultaneously situated in time (duration and point of time) and space (place, distance, range, and landscape). Education is thus imbued with value, even though the way education is experienced will differ depending on the range of local aspects. One aspect of living as a human being is related to the issue of time, in terms of generational age in infancy, toddlerhood, early youth or school years; or the teenage years; or as a young, middle-aged, or elderly adult; or in the final stages of life. Other influential aspects are gender, ethnicity/race, ableness, social status, or country of birth. Classical problems of the individual child's relation to, belonging to, and participation with pluralistic and heterogeneous local and global contexts occur and reoccur within this landscape across both Nordic and Australasian curriculum sites. The problem of how to maneuver the eternal question of "what constitutes the best interest of the child" in diverse local settings is not an easy one. Indeed, the project of *bildung* is even more relevant under such postmodern conditions. As Lyotard points out: "The old principle that the acquisition of knowledge is dissociable from the training (Bildung) of minds, or even of individuals, is becoming obsolete. . ." (Lyotard 1984, p. 5).

However, to fulfill the promise and potential of *bildung*, pedagogical practices in our time must go beyond the dichotomy of child-centered versus teacher-centered pedagogies to embrace notions of liberation and equity – we would argue that *bildung* and its ongoing conceptualization have much to offer in this regard.

Synonyms

First and second language literacy; Literacies

Introduction

Biliteracy has undergone definitional changes over the last two decades. Many changes in the field of biliteracy are related to theoretical shifts in how researchers view bilingualism and bilinguals. In this article, the authors define biliteracy and trace various perspectives on the literacy development of bilinguals. In particular, they present early definitions of biliteracy, examine the impact of sociocultural shift on the definition, explore the redefinition of bilingualism and biliteracy, highlight how research in psychology and neuroscience is aligned with educational discussions on biliteracy, look at research in the classroom, and call for continued expansion of research on biliteracy.

What Is Biliteracy?

The term biliteracy represents a fundamental shift from thinking about literacy as an activity that takes place strictly within a given language. Biliteracy, in the way it is being used here, represents what students are able to do with print across their languages, while recognizing that both of the students' languages are always present even when reading in one of their linguistic codes. Recent studies conducted by scholars in language education fields challenge the separation of languages during literacy instruction and support the benefits of translanguaging (i.e., bilingual education, see Baker 2011; multicultural education, see

Blackledge and Creese 2010; ESOL education, see Lindholm-Leary and Howard 2008; and foreign language education, see Fortune et al. 2008). Moreover, these studies reveal that following only monolingual instructional strategies is not always appropriate.

In the last three decades, researchers have documented students using their languages in ways that suggest an integrated language system. Students across these studies exhibited specific strategies linked to their bilingual ability, such as back translation (translating words from one language to the other), rehearse (testing out all the words they know), and postponing (using words in one language as a placeholder and returning to it at the end) (Wolfersberger 2003). Collectively, a view of students emerged as active learners who draw on linguistic features from both of their languages. Teachers who recognize and affirm students' metalinguistic knowledge consider these skills as resources to enrich students' bilingualism and biliteracy.

With regard to biliteracy specifically, the extent to which students displayed these skills depended upon their self-perceptions and confidence as readers. That is to say, students who viewed themselves as good readers used their metalinguistic skills and their understanding of cognates to navigate reading. Students who viewed themselves as less capable in reading did not see their bilingual ability as a skill set from which to draw on (Jiménez et al. 1996). Thus, bilingual programs with the most promise both affirm students' individual linguistic skills and create spaces for students to purposefully engage with each other across languages to scaffold each other's biliteracy development.

Early Definitions of Biliteracy

Bilingualism has often been described as linguistic proficiency in two separate languages. Traditional bilingualism espoused two separate linguistic systems (an L1 and an L2) with different linguistic features. This view of language development among bilinguals extended to their literacy development across the languages as well.

From this perspective, literacy development in one language mirrored literacy development in a second language thereby establishing the view of two parallel monolinguals (Grosjean 1989). Inherent in this view were a few assumptions. First, if biliteracy depended on bilingual learners' proficiency in each of their respective languages, then it was possible to compare their performance in both languages to monolingual speakers of those languages. Second, performance variations from the monolingual norm by bilinguals in either of their languages were regarded as "linguistic interference" in bilinguals' speech (Weinreich 1953). Missing from this parallel monolingual perspective is the notion that the addition of any language invariably augments students' linguistic repertoire. Moreover, academic contexts such as English-only classrooms, transitional bilingual education, or dual language classrooms impact differently how literacy is approached and subsequently developed.

Much of what is known about the literacy development of bilinguals is based on how emerging bilinguals in the USA come to read in English; thus, it is not surprising that transitional bilingual education is the most prevalent classroom structure for teaching students who are in the process of learning English. Within this framework, the learning of English is privileged over the maintenance of the home language. Although students start learning in their home language, by the second grade, they have transitioned to learning in English. This transition from home language to English often results in students viewing their first language as inferior. According to Wong-Fillmore (2000), these deficit perspectives of one's language lead to family members' inability to communicate with each other due to students' diminished home language skills. Students over time begin to marginalize their own culture because they see it through a deficit lens.

As a result, research conducted in transitional bilingual education programs provides only a limited understanding of biliteracy development. Moreover, transitional bilingual programs reify traditional beliefs that language separation is crucial for students to function similarly to monolingual speakers in two distinct languages. Such

programs implement curricula, pedagogical practices, and assessments, which focus on the school's privileged language. A monolingual approach toward bilinguals' literacy invariably limits the field's overall understanding of these students. The expectation that bilinguals transition from L1 monolingual to L2 monolingual hinders their ability to develop ethnolinguistic skills that extend beyond language acquisition and maintenance. Ethnolinguistics is a field that examines the relationship between language and culture and how different ethnic groups view themselves in relation to the world. Within this construct, biliteracy is not simply the ability to encode and decode written text; instead, it includes the ability to negotiate multiple ideologies. The flexibility inherent in translanguaging, then, is essential to bilinguals' self-expression as well as identity formation, both of which are deeply grounded in their biliteracy development.

The Impact of Sociocultural Shift

An important theoretical shift that influenced the view of bilingualism and biliteracy emerged from the work of Vygotsky (1978). Vygotsky's sociocultural theory asserts that the mind is socially constituted. Learners construct their understanding of various concepts through interactions with more knowledgeable others. Through these interactions, students are scaffolded to perform at a higher level than is possible when they work independently. Vygotsky reasoned that language and literacy represented cultural development. That is to say, the languages and literacies that students develop are a reflection of the cultural context that gave rise to them. In the case of children, more knowledgeable individuals in their lives pass on these cultural behaviors through scaffolding. Vygotsky's perspective toward development has had a strong influence on the way language and literacy is perceived in schools.

Regarding bilingualism, sociocultural theories have moved the dialogue from a strictly cognitive activity to something that is inherently social. Language is the vehicle used to navigate the social

world and therefore cannot be removed from the equation. Of equal importance, literacy itself is viewed as a social phenomenon. One comes to know and take part in literacy through social interactions. This shift in thought led some researchers to focus on the role of teacher practice, teacher ideology, and student peer interactions on literacy development. Although this theory allowed for social interactions to be considered in the development of literacy, it did not necessarily change the monolingual approach toward understanding students' languages.

Redefining Bilingualism and Biliteracy

Cummins (1979) questioned whether bilinguals' two languages were separate systems. He proposed a common underlying proficiency to explain how a cognitive interdependence allowed for transfer of linguistic practices even though the structural elements of the two languages might look differently. He argued bilinguals' understandings of literacy were not language bound and their linguistic abilities had to be understood beyond the surface. Cummins's theories of linguistic interdependence shifted the field of bilingual education and underscored the dynamic interrelationships that exist in the *linguaging* of bilinguals, that is to say, their language actions and practices in particular contexts.

Working toward a dynamic approach of bilingualism, Cen Williams, a Welsh educator, coined the term "translanguaging" for the planned and systematic use of two languages for teaching and learning during a lesson (Williams 1996). According to Williams (1996), translanguaging meant information was received through the medium of one language and used through the medium of the other language. Building upon Williams's notion of translanguaging, García (2009) proposed applying translanguaging to educate emergent bilinguals. García (2009) couched translanguaging within the frame of *dynamic bilingualism*, a form of languaging in which bilinguals draw from a *single linguistic system* with an innumerable amount of linguistic features. She argued that, unlike the view of two separate

systems that are added (or even interdependent), a dynamic conceptualization of bilingualism goes beyond the notion of two autonomous languages an L1 and an L2. Even in cases where curricular arrangements separate languages, students' translanguaging remains the most prevalent practice in bilingual education classrooms (García 2009). Students flexibly draw from their rich linguistic repertoire despite teachers' directives on when and how languages are to be used.

Researchers who use a sociolinguistics framework to support their work in translanguaging define biliteracy in ways that reveal an appreciation for the wide range of social contexts and languages with which students come into contact (e.g., school, home, community, etc.). Hopewell and Escamilla (2014) speak of global dexterity, which they define as the "ability to communicate both across and within multiple languages and cultures in a variety of ever-changing and nuanced contexts." Biliteracy is therefore, viewed as more complex than monoliteracy because students' literacy abilities have to be shown across a range of contexts and domains on a continua (Hornberger 1989; Hornberger 2004). This framing of biliteracy moves the field away from traditional dichotomous frameworks of literacy (i.e., monolingual vs. bilingual, social vs. academic language) to an understanding of the process of becoming biliterate across a variety of different settings and languages. In doing so, there is a call to better define what biliteracy means by looking more closely at the multiple contexts that give rise to biliterate students.

Psychology, Neuroscience, and Biliteracy

Research from the fields of psychology and neuroscience aligns with current notions of biliteracy and acknowledges that languages are interdependent and shape each other throughout development. In the last decade, there has been an upsurge of research on the consequences of executive function on bilingualism for language learning, language use, cognitive function, and brain development (e.g., Kroll and Bialystok 2013). These studies

have implications for literacy. It is important to note that studies using a range of methods with adults (young and old) and with children have shown that experience in using two or more languages increases the ability to be open to new learning and to adjust decision-making in light of conflicting alternatives. This presentation of the active language user is consistent with work in literacy that maintains the proposition that reading is a psychological guessing game informed by all the skills and knowledge that students bring to the task of reading. By defining reading this way, the reader is always negotiating as they read. Bilinguals, then, negotiate what they know about print-based reading across both of their languages. The effects of bilingualism are not restricted to language skills but apply more broadly to other domains of learning. The constant activity of bilinguals' negotiation between languages produces competition that requires resolution and that bilinguals effectively become expert in learning to negotiate the presence of two alternative language systems and that expertise confers a set of benefits to them across their life span.

Recent neuroscience research also shows that bilingual brains reflect the consequences of dual language experience, with increased functional efficiency in the neural networks that support cognitive control (e.g., Abutalebi et al. 2012). Even more provocative, a study by Carlson and Meltzoff (2008) reported benefits of bilingualism that can offset the impact of poverty on some cognitive tasks. They argued that low SES bilinguals were doing more with less (i.e., resources), but the benefits were evident only if students were in a dual language program for more than 6 months. The true impact of these findings still needs to be understood. The neuroscience field needs to further explore how SES and bilingualism impact cognitive functions developmentally and how the consequences of bilingualism can be used to better inform instruction for language and literacy development. The time has come to bridge psychology and neuroscience research with literacy education research (especially those focused on translanguaging). The classroom is precisely the context in which the first steps toward cross-discipline bridging might take place.

Biliteracy in the Classroom

Translanguaging allows us to understand the fluidity inherent in biliteracy. This flexible framework provides a lens and pedagogical approach through which to conceptualize biliteracy. This broader set of translingual practices, which are part of translanguaging, include language brokering (use of knowledge of more than one language to do things for others), code-switching (the practice of alternating between two or more languages or varieties of language in conversation), and metalinguistic awareness (ability to objectify language as a process as well as an artifact). By recognizing the nuances of these terms, teachers can better support students' biliteracy in their classroom.

Guided by a sociocultural framework, translanguaging allows us to view biliteracy as a set of skills that develop, in part, outside the classroom, which emergent bilinguals bring with them when they enter the school. In bilingual classrooms where students are encouraged to learn each other's languages through partnership, students shape each other's learning in ways that extend beyond the conventional Vygotskian view of a knowledgeable other scaffolding another person. In contexts where translanguaging is encouraged, students engage in organic and fluid linguistic and cultural relationships. That is to say, students who appear to be more knowledgeable and capable in one ethnolinguistic sphere are clearly learners in another and vice versa. The nature of bilingual classrooms calls on students to move along these dimensions in a continuous fashion, contributing to students' biliteracy development. In bilingual programs that provide supportive classroom conditions in which both languages are treated as legitimate languages of instruction and learning by the teacher and within the curriculum, biliterate students leverage what they know about both their written languages in order to create meaning in print. Dworin (2003) refers to this process as "bidirectionality of emergent biliteracy development" (p. 179). That is, students' knowledge about writing in one language shapes their writing across both languages.

The synchrony and flow of a co-learning relationship conceptualizes students roaming in and through languages whereby students are central to the “doing” of language (language) in the classroom. Common strategies include code-switching, the shift between two languages in context, translation, and acquiring information in one language and expressing that information in another language; however, when bilingual students perform bilingually in a classroom, translanguaging is manifested through their reading, writing, and discussion tasks, among others. Although some teachers consider translanguaging necessary for effective teaching in bilingual classrooms, many grapple with the practice and continue to look for ways to implement translanguaging to scaffold the development of literacies for emergent bilinguals in the classroom. Bridging languages in various classrooms can be seen in the work of researchers such as Velasco and García (2014) and Bauer et al. (2016), which show *how* students’ in schools are using their various, social, linguistic, and multimodal abilities to engage in biliteracy activities.

A Call to Further Expand Biliteracy Research

Much of what is known about biliteracy stems from research conducted through traditional paradigms in bilingual education, which limited the research scope to parallel monolingualism. As a result, studies focused on students attaining proficiency in the school’s language (i.e., English in the USA) and limited what could be said about biliteracy development across a variety of language pairs (such as, English-Spanish, English-Chinese). Research and teaching conducted under traditional paradigms lacked an understanding of the developmental trajectory across a variety of contexts and languages.

Although the research fields on translanguaging in education and executive function from psychology approach bilingualism and biliteracy differently, it is promising that both, in their own way, are addressing that students’ languages are always present and students’ responses

to their languages may hold the key to understanding their learning. What is less understood in education and psychology is how emerging bilinguals make use of the skills gained from being a bilingual to further enhance their academic development. It can no longer be assumed that understanding monolingual literacy is sufficient for understanding biliteracy. Although some of the above research is helping to redefine biliteracy, more research is needed to further understand how students navigate their languages and how they develop their literacies.

Buber, Martin (1878–1965)

Alex Guilherme
Pontifícia Universidade Católica do Rio Grande do Sul, PUCRS, Porto Alegre, Brazil

Introduction

Martin Buber (1878–1965), the well-known Jewish philosopher and theologian, is considered to be one of the greatest thinkers on education of the twentieth century. He was born in Vienna to an Orthodox Jewish family and spent most of his early life with his grandfather, who was a

prominent scholar of Midrash (Rabbinic *dialogue* with the Torah, the Old Testament), in Lvov, the capital city of Galicia (today's Ukraine). He was awarded a doctorate by the University of Vienna in 1904, for a thesis on Christian mysticism during the Renaissance and Reformation, and worked at the University of Frankfurt until 1933. He resigned from his position when the Nazis came into power and all Jews were excluded from teaching or studying in mainstream educational system, becoming involved in various educational ventures supporting the Jewish community in Germany. In 1938 he left Germany and settled in Palestine, becoming Professor of Social Philosophy at the Hebrew University of Jerusalem.

Philosophy of Dialogue

Buber's *I and Thou* [*Ich und Du*] (1923) is a major philosophical-theological work that deals with the most profound issues of what it is to be human and of human relations. Buber argues that human beings:

- i. Are relational beings
- ii. Are always in a relation with other human beings, or the world, or God
- iii. Possess a two-fold attitude toward other human beings, the world, or God, which is indicated by the *basic words* I-It (*Ich-Es*) and I-Thou (*Ich-Du*)

The *basic words* are a “linguistic construct created by Buber as a way of pointing to the quality of the experience that this *combination of words* seeks to connote” (Avnon 1998: 39) [*my emphasis*], so that I-It and I-Thou are read as “unities” indicating one's state of Being and attitude toward the *Other*, the *World*, and *God*. This means that there is no *I* relating to a *Thou* or to an *It*; rather, what exists is a kind of relation encapsulated by the unification of these words. Avnon (1998: 40) comments insightfully that “one may summarize this point by suggesting that the difference between the I-You and the I-It relation to being is embedded in the hyphen.” The hyphen of I-Thou indicates the kind of relation that is inclusive to the Other, while

the hyphen of the I-It points to the sort of relation that is not inclusive to the Other, that in fact separates the Other. Buber (2004: 3) characterized these *basic words* succinctly as “the primary word *I-Thou* can only be spoken with the whole being. The primary word *I-It* can never be spoken with the whole being.”

The I-Thou relation, the dialogical relation, is an *inclusive* reality between individuals. Buber argues that the I-Thou relation lacks structure and content because when a human being “encounters” another through this mode of Being, an infinite number of meaningful and dynamic situations may take place in that which Buber calls “the Between.” Thus, it is important to note that any sort of preconception, expectation, or systematization about the Other prevents the I-Thou relation from arising (cf. Theunissen 1984: 274–275) because they work as a “veil” or a barrier to being *inclusive* toward the Other. Through I-Thou relations, this *inclusive* reality, one allows the Other to present himself or herself to one with the fullness of his or her being, and vice versa. Despite the fact that it is difficult to characterize this kind of relation, Buber argues that it is real and perceivable, and examples of the I-Thou relation in our day-to-day life are those of: two lovers, two friends, and a teacher and a student. It is important to emphasize that one of the reasons Buber avoids presenting a list of steps and techniques for I-Thou relations is that he views it as a situational accomplishment; “there are many ways to ‘do’ dialogue, and one cannot predict in advance exactly what it will take for this quality of contact to come into being” (cf. Stewart and Zediker 2000: 230).

While in the I-Thou relation two beings are *inclusive* to each other, in the I-It relation entities fail to do so. Instead, in the I-It relation, a being confronts another being, objectifies it, and in doing so *separates* itself from the *Other*, “turning away from the Other.” This is in direct contrast with I-Thou relations because the “‘I’ of I-It relations indicates a separation of self from what it encounters” and “[b]y emphasising difference, the ‘I’ of I-It experiences a sensation of apparent singularity – of being alive by virtue of being unique; of being unique by accentuating

difference; of being different as a welcome separation from the other present in the situation; of having a psychological distance ('I') that gives rise to a sense of being special in opposition to what is" (Avnon 1998: 39). Thus, when one engages in I-It relations, one separates oneself from the Other and gains a sense of being different, special, and, arguably, superior at the same time.

Buber understood that human existence consists of an oscillation between I-Thou and I-It relations and that the I-Thou experiences are rather few and far between. However, if I-It relations become too dominant to the point of suppressing I-Thou relations, this becomes problematic as it is as if "one diminishes oneself as a human being" because I-Thou relations are a fundamental part of the human condition. It is also important to emphasize that Buber rejects any sort of sharp dualism between the I-Thou and I-It relation. That is, for Buber there is always an *interplay between* the I-Thou and the I-It rather than an *either-or* relation between these foundational concepts. The I-Thou relation will always slip into an I-It relation because it is too intense, but the I-It relation has always the potential of becoming an I-Thou relation. This oscillation is very significant for it is the source of transformation, because through every I-Thou encounter, the I is transformed, and this affects the I's outlook of I-It relations and of future I-Thou encounters. Putnam (2008: 67) notes that "the idea is that if one achieves that mode of being in the world, however briefly ... then ideally, that mode of being ... will *transform* one's life even when one is back in the 'It world'." It is through I-Thou encounters that one realizes that one is responsible for Others. As Buber (1936/2002: 52) says: "Responsibility presupposes one who addresses me primarily, that is, from a realm independent of myself, and to whom I am answerable." Thus, in I-Thou moments, "if someone comes to you and asks for help, you shall not turn away with pious words... You shall act as if... there were only one person in all the world who could help this man – only yourself" (Buber 1991: 89).

But it is not just through engaging concretely in I-Thou relations that the I is transformed as it is

also arguable that the realization that one has failed to engage in I-Thou relations is also transformative. That is, the failure to establish a *dialogical between* leads one to experience an *existential guilt*, which prompts one to seek *reconciliation with oneself and with the world*. In connection to this, it is interesting to note a personal life turning event in Buber's life. In "A Conversion," a subsection of *Dialogue*, Buber recounts that on one occasion a young man came to see him on a Saturday afternoon after morning prayers at the synagogue in search of advice. Buber recalls that he was pleasant to the young man but that he did not "open up" to him, resulting in the young man leaving without asking for Buber's advice; however, soon after Buber learned that the young man had died. This event haunted Buber as he realized that he had missed an opportunity to engage in I-Thou relations with the Other (cf. Buber 1929/1961a). Thus, the I is not just transformed by every I-Thou encounter, it is also transformed by the I's realization that it failed to establish a dialogue with the Other.

Levinas, whose career overlapped by a few decades and who maintained contact with Buber, provides us with an important criticism of Buber's views on dialogue, that is, I-Thou relation is merely an exchange between friendly partners (cf. Levinas 1963). Buber (1967: 723) replied by saying that "Levinas errs in a strange way when he supposes that I see in the *amitié tout spirituelle* the peak of the I-Thou relation. On the contrary, this relationship seems to me to win its true greatness and powerfulness precisely there where two men without a strong spiritual ground in common, even of different kinds of spirit, yes of opposite dispositions, still stand over against each other so that each of the two knows and means, even in the severest conflict, as this particular person. In the common situation, recognizes and acknowledges, accepts and confirms the other, even in the severest of conflict, as this particular person."

Another common criticism of Buber's views on dialogue is that even if one accepts that we, as human beings, can relate to each other through dialogical and non-dialogical relations, it might be difficult for some to accept that we can relate to things in the world (i.e., natural or artificial) and

God in the same manner. That is, some would argue that there is something fundamentally different in the way human beings relate to each other, dialogically or not, and the way we relate to the rest of creation and God.

Philosophy of Education

Buber's understanding of *dialogue* is the cornerstone of his views on education, and his *The Address on Education* (1925) and *The Education of Character* (1939) are some of his most important texts. In *The Address on Education*, delivered at the Third International Educational Conference in Heidelberg, Buber argues against both teacher-centered education (top-down or as Buber says "funnelled in") and student-centered education (bottom-up or as Buber says "pumped out") which were being discussed at the time, particularly in Germany (cf. Buber 1925/1961c). In another lesser known essay, *On National Education*, which was written many years later, Buber (1963/1997) continues to criticize teacher-centered and student-centered education through the use of metaphors, demonstrating that he did not change his mind about these approaches. Buber argues that in teacher-centered education, the teacher is like a *sculptor* who seeks to shape the student in accordance to that which is considered right, while in student-centered education the teacher is like a *gardener* who prepares the environment to enable the student to develop his or her potentialities as they arise; Buber (1963/1997: 150) concluded that "the gardener has not enough confidence; the sculptor has too much."

For Buber, both teacher-centered and student-centered education remain within the realm of I-It relations because there is no real *dialogue*, I-Thou relations, between teacher and student, as well as not encouraging this between students. His critique of these approaches to education suggests that Buber is arguing for a third-way between these approaches, which is something not always easy to do. Hence, what is important in education is that it must be based on *dialogue*, on the inclusion of the Other, meaning that both teachers and students feel accepted, comfortable in being who

they are, and trusting of others; in contrast to this is the kind of relation not based on *dialogue*, on the separation of the Other, which leads to a lack of interest on both parts, and even rebellion in extreme cases.

This critique of teacher-centered and student-centered approaches leads Buber to argue that education is always the education of *character*. One of his key texts on education provides us with evidence of this. Buber (1939/1961b: 123) opened his address to the National Conference of Teachers at Tel Aviv, in 1939 (published as "The Education of Character" but also known as "An Address to the National Conference of Palestinian Teachers") with the following powerful statement: "Education worthy of the name is essentially education of character. For the genuine educator does not merely consider individual functions of his pupil, as one intending to teach him only to know or to be capable of certain definite things; but his concern is always the person as a whole, both in the actuality in which he lives before you now and in his possibilities, what he can become."

In this passage Buber is stressing the tension between that which we would call the concepts of *Bildung* and *Erziehung* in "education." In English the term "education" encompasses all aspects of the teaching-and-learning process; however, in German, Buber's native language, there is a differentiation between different features of the process. *Erziehung* stands for instruction and the learning of a skill or trade, while *Bildung* denotes the education of character. Buber understood that *Erziehung* is a relatively easy undertaking because it consists in teaching individuals to perform various tasks successfully, but *Bildung*, ethics and character formation, is not so simple (cf. Morgan and Guilherme 2013: 56–57). Buber was aware that there is a friction between these two aspects of the educational process (cf. Weinstein 1975: 47–51) as he noted in a personal anecdote: "I try to explain to my pupils that envy is despicable, and at once I feel the secret resistance of those who are poorer than their comrades. I try to explain that it is wicked to bully the weak, and at once I see a suppressed smile on the lips of the strong. I try to explain that

lying destroys life, and something frightful happens: the worst habitual liar of the class produces a brilliant essay on the destructive power of lying. I have made the fatal mistake of giving instruction in ethics, and what I said is accepted as current coin of knowledge; nothing of it is transformed into character building substance” Buber (1939/1961b: 124).

The education of character is therefore rather difficult, and it involves engaging with students through *dialogue*, I-Thou relations. Teachers and students must relate to each other by being *inclusive*, by making space to the Other to present himself or herself as he or she is. Engaging in I-Thou relations, inclusive dialogical relations, implies that the teacher must invite the student to engage with reality, with the big questions affecting the world, and not be afraid of doing so. This can be exemplified by referring to an interesting passage of “The Education of Character” (1939), where Buber imagines a teacher and students discussing events in the early part of the twentieth century when Arab terror against Jewish communities in Palestine, and Jewish reprisals against Arab communities, occurred. The central question for this debate is “Can there be a suspension of the Ten Commandments...?” (Buber 1939/1961b: 129). As the dialogue unfolds the discussion becomes tense because ethical decisions are never clear-cut, and leading to wider implications and more questions. However, without such engagements the educational process becomes pale and confined to *Erziehung*, to rote learning, to the mere memorization of facts and figures, and to the learning of particular skills, and arguably uncritical. As a consequence of this, *Erziehung* is not able to expand into *Bildung*, into character formation, into allowing one to develop oneself as an ethical and critical being. That is to say, *Erziehung* is the kind of education that is based on non-dialogical relations, on I-It relations, such as teacher-centered and student-centered, which contrasts to *Bildung*, the sort of education that encourages the rise of dialogical relations, of I-Thou relations, the third-way Buber encouraged us to take.

Further, this engagement needs to be a constant in education, it must be part and parcel of it, so that the student’s character develops and he or she

becomes fully aware of the moral weight of his or her actions upon himself or herself, his or her community, and the world. The teacher plays a crucial and central role in all of this, which goes against notions of the teacher as a mere “facilitator” in the classroom; rather, the teacher is someone who, by virtue of his expertise and through establishing dialogical relations with his students, helps students to discover things about themselves, their societies, and the world (cf. Guilherme 2014). Buber (1939/1961b: 137) comments that the educator “can awaken in young people the courage to shoulder life again... [h]e can show that even the great character is not born perfect, that the unity of his being has first to mature before expressing itself in the sequence of his actions and attitudes. But unity itself, unity of the person, unity of the lived life, has to be emphasized again and again.”

This means that Buber’s approach is fundamentally existentialist in nature. The individual, whether teacher or student, must gain a full understanding of the human condition; that is, that we as human beings are always in a relation, that we are only capable of engaging in I-Thou and I-It relations with Others, and that our choice of how to engage with the Other carry a moral weight with it. Our choices of engagement have a direct effect upon ourselves, on Others, and in the world. Weinstein (1975: 51) commented on this aspect of Buber’s philosophy by noting that “[a] great character is one who by his actions and attitudes satisfies the claim of the situation out of deep readiness to respond with his whole life, and in such a way that the sum of his actions and attitudes expresses at the time the unity of his being and his willingness to accept responsibility.”

Conclusion

For Buber dialogue, I-Thou relations, is the establishment of a mutual and inclusive relation with the Other, and this is in contrast with non-dialogical relations, I-It relations, which are based on the objectification of and separation from the Other. Further, Buber’s theory of dialogue draws our attention to the fundamental

importance of the quality of “relations” between teacher-student and student-student in education, which is something not always at the forefront of educational practices that very often tend to focus on issues of methodology, learning environment, and achievements to the detriment of relations.

The University of Auckland, Auckland,
New Zealand

Albert Camus (1913–1960), novelist, dramatist, philosopher, essayist, was born in Algeria on 7 November 1913. His mother was Spanish and his Breton father was killed in World War I in 1914. Camus was raised and studied under difficult but reasonably happy circumstances: “though I was born poor, I was born under a happy sky in a natural setting with which one feels in union, unalienated.” Initially a journalist in Algiers, and later in Paris, he was Editor of *Combat*, the underground resistance newspaper from 1942 to 1946. Camus, like his friends Jean-Paul Sartre and Simone de Beauvoir, was then an active member of the resistance. He was but 46 when he was killed instantly in a road accident in January 1960, having been offered a lift back to Paris by a close friend (Roger Gallimard, the publisher, who later died of injuries sustained in the crash). The Nobel Prize for literature was awarded to Camus in 1957.

While his major interest was mainly in literature, he studied philosophy at Algiers University and wrote didactic texts which are certainly philosophical. In philosophical histories or dictionaries, he is usually listed under French existentialism and accorded higher status, as philosopher,

than Simone de Beauvoir. Camus rejected the category “existentialist.” For many years a friend of Jean-Paul Sartre and Beauvoir, they were to experience a massive “falling out.” But this had earlier roots, to do with jealousy, with Camus’ fierce individualism, combined with a post-political ethics, and a refusal to commit himself politically to causes at a time after WWII when Sartre, under the influence of Beauvoir, was moving away from his earlier violent and alienated notion of the individual. The final straws were probably Sartre siding with the Communists (Camus would have no truck with them), an intemperate review of *L’Homme Révolté* in *Les Temps Modernes*, and an equally intemperate reply by Camus. Sartre responded equally as badly to Camus in *Les Temps Modernes* (August, 1952): “... you may be my brother – brotherhood is cheap – you certainly aren’t my comrade” (Sartre 1952). (But they had been comrades in the resistance).

Camus had enormous consideration for others and was extremely generous, perhaps to a fault. In his early days, Beauvoir said that she liked “the hungry ardour” of their companion yet that he could become concerned that his generosity was received with ingratitude. He could become formal in discussion if not righteous and, “pen in hand, he became a rigid moralist” (Beauvoir 1968, p. 61). Perhaps the acclaim and his good luck went to his head. Nor as a moralist did he have time for the deliberations and the risks involved in translating his moralism into political

thought and action. In his later life, he was probably closer to Gaullism than socialism, refusing to denounce colonialism in Algeria in Stockholm where he was to be awarded his Nobel Prize. But in an ever-increasing modernism and performativity, Camus traces the disappearance of old Europe and the “spaces” where morals and justice are being replaced by the spaces of new technologies.

The essential philosophical thought of Camus is to be found in *Le Mythe de Sisyphe* (1943) (*The Myth of Sisyphus* [1943]) and *L'Homme Révolté* (1951) (translated into English as *The Rebel* [1969]), although there are differences and developments between the two. These ideas are of course explored in his novels. A major thesis of Camus, in both tracts, is the problematization of death. In the earlier tract it is suicide, and in the latter it is the death of others, especially murder. They do not involve studies of death but, instead, attitudes toward death. If we can have experience of “other things,” we cannot experience death; Camus argues that, at best, any “experience” is second hand and parasitic. Camus’ ongoing point is that we can have no experience of death, in the sense that we experience sense data, emotions, etc., but that death is, as human beings, our only certainty. He has been titled as the writer of the absurd which, in his thought, can be described as the confrontation between our human demands for justice and rationality with a contingent and indifferent universe. Hence, life is meaningless. Yet, we must accept the absurdity of life and we must go on living – Sisyphus accepts his futile fate. But, “Finally I come to death.”

In *Le Mythe de Sisyphe*, absurdity is a sensation or feeling, which seizes us suddenly. It is at the base of thought and action, even though it is indeterminate and confused and, if present, it is distant in time. Time is our worst enemy, causing us to place ourselves in time and live with the future in mind – we are ardent for tomorrow – even though much of life is mechanical repetition. Faced by the absurdity of life, consciousness becomes crucial to Camus’ thought – it is the only good and the real good. It permits one to discern meaning, and, as the world has no meaning, it is ultimately absurd (though it

is the relationship between consciousness and the world which is said to be absurd).

Our reaction to this experience of absurdity is pursued in *L'Homme Révolté*. Metaphysical rebellion is the answer to absurdity. It “is the means by which a man protests against his condition and against the whole of creation . . . it disputes the ends of man and creation. . . (it) protests against the human condition . . .” (*The Rebel*, p. 29). Rebellion indefatigably confronts evil. But it also sets limits, beyond which one cannot go, for rebellion without limits ends in slavery: “. . . he who dedicates himself to the duration of his life, to the house he builds, to the dignity of mankind, dedicates himself to the earth . . . and sustains the world again and again” (*ibid.*, p. 267).

There is then a message of hope in rebellion because consciousness can make the walls, or limits that could not formerly be penetrated, transparent. Consciousness is promoted by the absurd. There is a promise of a real awakening and no chance of returning to repose. But here Camus stops. There are no principles which define an appropriate rebellion. He is not so much theoretical here but practical. Each situation is new and the appropriate action determined by the analysis of that situation. Camus was against violence, but under certain conditions the rebel would choose limited and brief violence. On the eve of the liberation of Paris in WWII, he wrote in *Combat*: “. . . the barricades of freedom have once more been thrown up. Once more justice must be bought with the blood of men . . . their reasons must then have been overwhelming for them suddenly to seize the guns and shoot steadily, in the night, at those soldiers who for 2 years thought that war was easy” (Camus 1944).

There are limits then between opposites and moderation is the key. There are dualisms such as life and death, love and hatred, “tenderness” and “justice,” and justice for man against the contingencies of history. Somewhat paradoxically the rebel must at one and the same time reject and accept history and simultaneously deny and affirm. Camus always sought a middle path, an equilibrium, and moderation. But without principles for such moderate forms of rebelling, Camus seems almost anarchistic.

This concept of absurdity of the human condition is to be found in the Theatre of the Absurd which uses a variety of dramatic techniques which defy rational analysis in their presentation of the absurdity of the human condition. The term was coined by Martin Esslin in 1961, but he developed the notion of the absurd from Camus' *Le Mythe de Sisyphe*. Dramatists to whom this title might be applied include Eugene Ionesco, Samuel Beckett, and Harold Pinter.

Talking of the death of her former friend, Simone de Beauvoir was to say:

it wasn't the 50-year old man who'd just died I was mourning; not that just man without justice, so arrogant and touchy behind his stern mask ... it was the companion of our hopeful years, whose open face laughed and smiled so easily, the young ambitious writer, wild to enjoy life, its pleasures, its triumphs and comradeship, friendship, love and happiness. Death had brought him back to life; for him time no longer existed. (Beauvoir 1968, p. 497).

Sartre, in a eulogy for him in France-Observateur, on 7 January 1960 said:

He was, in this century and against history, the current heir to that long line of moralists whose works perhaps constitute that which is most original in French letters. His stubborn humanism, narrow and pure, austere and sensual, battled uncertainly against the massive and misshapen events of this our time. But, inversely, through his obstinate refusal, he reaffirmed, in the heart of our era, against the Machiavellians, against the golden calf of realism, the existence of morality. (Sartre 1960, p. 110).

Canguilhem and Philosophy of Education

James D. Marshall
The University of Auckland, Auckland,
New Zealand

Georges Canguilhem was born on 4 June 1904, at Castelnaudary near Toulouse, in South West France. He died on 11 September 1995 at the age of 91.

Success at Castelnaudary Lycée (where he was a boarder), and the award of a scholarship to study at the prestigious Lycée Henri-IV in Paris, enabled him to gain entrance to the École Normale Supérieure in 1924. In his cohort were Jean-Paul Sartre, Raymond Aron, and Paul Nizan. Later there were Maurice Merleau-Ponty and Jean Cavaillès. He was influenced by his teacher Alain (Emile Chartier) at Henri-IV, by Cavaillès whom he succeeded at the University of Strasbourg in 1941, and by Gaston Bachelard, whom he succeeded as Professor of History and Philosophy of Sciences at the Sorbonne and as Director of the Institut d'Histoire des Sciences and Techniques, in 1955. In addition to his qualifications in philosophy, he gained a Doctorate in Medicine at the University of Strasbourg in 1943. His doctoral thesis was to be republished several times and translated into English as the *Normal and the Pathological* in 1978 (with an introduction by Michel Foucault). He also occupied the important administrative post of Inspecteur Général de Philosophie between 1948 and 1955, having initially refused it at the time of the Liberation. In this post he was responsible for the teaching of philosophy in lycées. His writing was austere and he was noted as an exacting if not intimidating

examiner. Nor was he the typical French intellectual, pronouncing on almost anything and prepared to occupy a radical political platform. If he was on the left, he was not on the radical or revolutionary left. For full bibliographical details and accompanying biographic comments, see Camille Limoges (1994). For a fuller historic account in English of Canguilhem's life, see David Macey (1998).

His friend Jean Cavaillès, who was to be assassinated by the Nazis in January 1944, had encouraged him into the resistance (if encouragement were needed – given his “rebellious” stances at ENS and his early opposition to events in Germany). After the Gestapo raid on the *Faculté des Lettres* at the University of Strasbourg (by then in Clermont-Ferrand) in 1943 and in which two professors were killed and many students and professors deported to Germany (but which he managed to evade), he was forced underground where he took a major part as a doctor in the Auvergne Maquis (code name “Lafont”). He was awarded the Military Cross and the *Médaille de la Résistance* in 1944. Later, in 1976, he was to publish a study of his former student, colleague, and comember of the resistance Jean Cavaillès: *Vie et mort de Jean Cavaillès*.

Unlike Bachelard, who took physics and chemistry as historical examples of scientific rationality, he took as his major sources biology and medicine. It could be said that in selecting biology and medicine and in rejecting great scientific events such as the Copernican Revolution, he forged a change of course in French History of Science. Biology and medicine were not as rigorous as physics and chemistry and are inextricably intertwined with nondiscursive practices. Foucault is to extend this displacement further to the human sciences.

If Canguilhem was a historian of science rather than a philosopher of science, then he was also a historian who was extremely sensitive to philosophical issues. According to Dominique Lecourt (1975, p. 165 f.): “There is probably no better definition of the history of the sciences as it is conceived and practised by Georges Canguilhem himself...it seems completely justified to make

him Bachelard's heir.” But his history is also epistemological. For Canguilhem, “the history of science is the history of an object – discourse – that is a history and has a history, whereas science is the science of an object that is not a history, that has no history” (Canguilhem, as cited in Delaporte 1994, p. 26). Thus (ibid.):

...the object of the history of science has nothing in common with the object of science. The scientific object, constituted by methodological discourse, is secondary to, although not derived from, the initial natural object. ...The history of science applies itself to these secondary, non-natural, cultural objects. It is a discursive project about scientific objects'. But it is also concerned with “the progress of the discursive project”, a progress which may “meet with accidents, be delayed or diverted by obstacles, or be interrupted and truth.

The objects of the history of science are then very different from the objects of science. For Canguilhem science arrests time, construing its objects as nontemporal and as not having a history. The full reality of the scientific object is in principle available to the scientist in the present. It is of course true that these objects exist in time and change through time. However, the objects of history of science are regarded themselves as part of a historical development which has not yet finished. The objects of history of science are incomplete. Whereas the objects of geology can be treated as complete, as “givens” open to analysis, the objects of history of science cannot, as their value and meaning are determined first by an epistemological and normative judgement and, second, are always in principle open to reevaluation as to their value and meaning in accordance with the progress of science.

Canguilhem's epistemological concern then is with the history of concepts. The philosopher's aim is to identify “the order of conceptual progress that is visible only after the fact and of which the present notion of scientific truth is the provisional point of culmination” (Canguilhem 1988, p. 9). But this history of concepts is not the history of ideas. Nor is it a history of terms, or of phenomena, or even of theories. Perhaps the elimination of these possibilities can make clearer his view of the history of science.

If there were such a thing as a history of terms, then it might concern itself with exploring the use of a term from its historical antecedents to more modern usages. For example, the term “atom” in current use in modern science was also employed by the pre-Socratics. However, while the same term or word was used by both pre-Socratics and contemporary scientists, the referents of these terms have almost nothing in common. Such a history was not Canguilhem’s.

Nor is the history of concepts to be identified with a history of phenomena. For example, someone might produce a history of volcanic eruptions and earthquakes in, say, New Zealand. What would be crucial here for Canguilhem is not what is observed – the phenomena – but the interpretation of those phenomena. It is not enough then for someone to observe and describe phenomena no matter how new, or unexpected (perhaps as the result of a Baconian experiment), for that person to have a scientific concept, or to be doing science, or to be writing the history of science. One cannot explain in observational terms (thus for Canguilhem, Priestly did not have a concept of oxygen, whereas Lavoisier did; Gutting 1989).

But Canguilhem also insists upon the separation of concepts from any theories which may “use” those concepts. Concepts are not imbedded in theories, and they do not derive their meaning from associated theories. Instead concepts permit one to identify data in a scientifically meaningful and useful manner: theories explain the data and/or phenomena identified prior to explanation by concepts. Concepts permit scientific questions to be formulated and theory provides scientific answers to those questions. Concepts are also claimed to be “theoretically polyvalent” (Canguilhem 1988, p. 6). This means that one and the same concept can occur in different theories. Thus, Canguilhem was able to write the history of the reflex arc, a concept which occurs in several quite different theories. This is not to deny that a concept may become reformulated and transformed between theories, but if the concept retains an underlying fundamental scientific content, it is still the same concept.

Canguilhem believes that there is a close relationship between concepts and phenomena. If he is rejecting the distinction sometimes claimed between (neutral) facts and theories, he is not doing so in any simplistic fashion which claims that there are no observed facts apart from their theoretical interpretations. His position is more complex as he makes distinctions between terms, concepts, and theories. Concepts which are theoretically polyvalent identify phenomena, not necessarily or merely theories. Instead theories explain those phenomena identified prior to explanation by concepts.

Clearly Canguilhem does not view the history of science as itself possessing scientific status. Such a view of the history of science would see it in positivistic manner as presenting already constituted objects from the past of science to be scrutinized by the historian of science, just like any other data in a laboratory. What is wrong with this approach is Canguilhem’s insistence that history of science is normative. Here he would seem to be following Bachelard in believing that the historian’s judgements of the past are informed by the present. This involves a form of epistemological analysis which furnishes to the historian the principles for informed judgement of the past. Clearly there are normative notions associated with the evaluation of science’s achievements and progress.

On the Normal and the Pathological is the work for which Canguilhem is best known. Not only was it important in the area of medicine, but it was important for other areas of the human sciences. As Foucault said in the Introduction to the English version, this work was important “for those very people who were separated from, or challenged, the establishment.” It was the work of Cavaillès, Bachelard, and Canguilhem on “a philosophy of knowledge, of rationality and of concept” which was important in the crises of the universities and the status and role of knowledge in the 1960s, rather than “a philosophy of experience, of sense, and of subject,” i.e., of Sartre and Merleau-Ponty, according to Foucault (Canguilhem 1978, pp. ix–x). If that is the case, however, for Canguilhem, the events of 1968 were not easy or comfortable, as he had given

his life to the academy and may have been seen as a mandarin (Bourdieu 1998, p. 191).

This work was essentially his medical doctoral thesis. He attacked the notion that the concepts of the normal and the pathological, so essential to the thought and activity of medicine, could be interpreted in a straightforward positivistic and statistical manner. He attacked the fundamental notion that normal was a statistical mean, because that amounted to conceiving and treating a living system as if it were structured and therefore governed in a lawlike manner. If that were the case, it would have been in some preestablished harmony with the environment. Instead, Canguilhem argues, the human organism is a living vital organism which is by no means in any preestablished harmony with its environment, for “The laws of Galilean or Cartesian mechanics cannot by themselves explain the origin of coordinated organ systems, and such coordinated systems are precisely what one means by ‘life.’ In other words, mechanism is a theory that tells us how machines (living or not) work once they are built, but it tells us nothing about how to build them” (Canguilhem in Delaporte 1994, p. 78).

Thus, for Canguilhem, the normal begins instead with the living organism and an order of specific properties, arguing that medical practice must be based upon the diversity of life which in turn provides the paths for its own conceptualization and for the restoration of its normal state. “To say that ‘no doctor proposes to produce a new kind of man, with a new arrangement of eyes or limbs’, is to recognise that an organism’s norm of life is furnished by the organism itself, contained in its existence” (Canguilhem 1978, p. 159). Therefore, we must proceed from life to understanding and not from understanding to life and thus define life as a meaning inscribed in matter. Lecourt (1975, p. 184) translates this position into the form of an equation:

$$\begin{aligned} < \text{life} = \text{code} = \text{information} \\ &= \text{concept of life} = \text{concept} > . \end{aligned}$$

Essentially for Canguilhem then, normality means the ability to adapt to changing circumstances, to environments which are both various and variant.

It thus involves activity and flexibility so that the living being lives in shifting relationships with a continuously changing environment. Medical dictionaries define the normal as “that which conforms to the rule, regular.” Canguilhem extends this brief definition as follows: “(1) normal is that which is such that it ought to be; (2) normal, in the most usual sense of the word, is that which is met in the majority of cases of a determined kind, or that which constitutes either the average or standard of a measurable characteristic” (Canguilhem 1978, p. 69). For Canguilhem and his views on life and concept, there can be no such sense of a pathological normal for living organisms, and hence, there can be no purely objective pathology (Rabinow, in Delaporte 1994, p. 16).

Canguilhem’s thesis on life is known as vitalism. Gordon (1998, p. 185) states the thesis thus:

- Life is an irreducible concept and one which is necessary to science;
- Its content is given through experience as living beings as well as our observation of living beings;
- Our conceptual activity in general is a continuation and extension of our existence as living beings.

Also, for Canguilhem (1952, p. 143), machines are seen as an extension of living organisms: “Un outil, une machine ce sont des organes, et des organes sont des outils ou des machines.” His point is not that tools and machines are organisms but that they are extensions of the body (Hacking 1998, p. 207). His work here, directed as much against Cartesian dualism, has obvious implications for the philosophy of technology.

In education there are at least three broad parameters along which a Canguilhem-inspired research program might proceed. First, there is the importance for the human sciences, including education, of Canguilhem’s approach to epistemology, especially his emphasis that this must be a historical epistemology. If this is being traced in the general area of the social sciences in Anglo-American thought (see, e.g., Economy and Society, 27 [2&3], 1998), it is almost nonexistent in education (though see Marshall 1996, pp. 47–53).

What would be of concern here is the specific nature of rationality in education, especially those aspects of educational theory and research which laid claim to scientific status and the role which critical historical thought might play in relation to “the” vital form of life displayed in a living organism. Second, there is a need for a deeper exploration of the notion of “normal” in educational thought and theory. Canguilhem’s notion of the norm as not being statistical but, instead, to be associated with normativity, that is, the ability of a living organism to adapt with activity and flexibility to changing circumstances, would be more than helpful here. Finally, his views on vitalism, normativity, and the notion that tools and machines are extensions of living organisms have interesting possibilities for problematizing the educational thrust toward technology.

For “extensions” of the ideas of Canguilhem to the human sciences, see entries for Michel Foucault, particularly “Foucault on Science.” See also entries for “Bachelard, Canguilhem and Foucault on Science” and “► [Educational Change/Reform and Norms.](#)”

Castoriadis on Autonomy and Heteronomy

Ingerid S. Straume

Reference and Research Section, Oslo University Library, University of Oslo, Oslo, Norway

Synonyms

Democracy; Freedom; Reflexivity; Self-questioning

Introduction

Cornelius Castoriadis (1922–1977) was a Greek-French philosopher, psychoanalyst, and political thinker-activist who has contributed original insights to a wide range of fields. Autonomy – and its antithesis, heteronomy – was a central and enduring interest of Castoriadis that he explored and elaborated in various settings, including ancient and modern democracy, workers' self-management, and the living being. In most of his work, there is a sense of importance, a political urgency, which informs the reader that academic work is not a neutral or disinterested activity. However, his philosophical work is oriented toward *praxis* and not aimed at developing theoretical principles, as shown in his criticism of Marx (Castoriadis 1987) and Rawls (Castoriadis 1997a). This means that, for Castoriadis, what autonomy would look like in practical terms is not something that could be deduced and described by philosophers – theoretically, in advance – but a creative act of reflexive self-determination by the subjects in question.

The thought of Castoriadis is anti-foundationalist, not postmodernist, but sometimes dubbed post-phenomenological (Adams 2008). He developed an ontology of “magma” indicating that the world itself can only be known partially, “in fragments.” His philosophy is orientated toward notions of creation, the imaginary, and *praxis* without ever abandoning the ideals of the Enlightenment, such as the quest for truth,

freedom, democracy, and autonomy. Recently, his concept of social imaginary significations has been an important inspiration for the notion of social imaginaries in social theory, while his political thought was influential in the student revolt of May 1968.

Greek in origin, Castoriadis came to Paris in 1945 on a student scholarship and spent the rest of his life there. In France, he became a well-known political thinker-activist on the antiauthoritarian left, as leader of the group *Socialisme ou Barbarie* together with Claude Lefort. The group was influential, but had many conflicts over political orientation, not least when Castoriadis decided to break with Marxism in the 1950s. During the 1960s, he nurtured a growing interest in psychoanalysis and ontology, and in 1975 his main *oeuvre*, *The Imaginary Institution of Society*, was published in France. His late introduction to the English-speaking world is partly due to a late translation to English (1987) and partly to his status as an underground political thinker who, due to French law under de Gaulle, had to write under pseudonym for the first 25 years.

Autonomy Is a Project

In order to understand Castoriadis's notion of autonomy, we have to take the concept literally. *Autos nomos* refers to following laws or rules that are given to the self, by the self, as opposed to the laws provided from the outside or by others (*heteros nomos*). In general terms, Castoriadis conceives autonomy as “the capacity, of a society or of an individual, to act deliberately and explicitly in order to modify its law – that is to say, its form [*nomos*]” (Castoriadis 1997b, p. 340). However, this notion differs in important respects from liberal, Kantian inspired autonomy where the relevant self (*autos*) is an individual who seeks to reduce the influence of others when making their own, independent judgments. For Castoriadis, this kind of a social individual is either inconceivable or psychologically and morally unfit. For him, autonomy is something that is instituted by the social-historical, which makes it simultaneously an individual and a collective

phenomenon. Put in his own terms, autonomy refers to a special kind of imaginary signification that is (or is not) instituted by the social-historical. When instituted in a given society, autonomy plays a key role whenever individual members of that society pass their judgments, make their choices, and reflect upon their commitments in politics, education, and the full range of public affairs.

In Castoriadis's analyses the social-historical dimension is always primary. Of course, as a practicing psychoanalyst, he was not uninterested in individuals, their psychic life, and so forth, but his approach to theorizing the individual subject goes *via* the social-historical. His reasons involve several aspects. Most important is his acknowledgment of historicity: It is not possible, for Castoriadis, to theorize and understand an individual person without taking into account the sociohistorical setting that has formed this person's beliefs, desires, motifs, and so forth. Observing that the social-historical is rather poorly understood, especially in terms of how a society creates and recreates itself, Castoriadis developed his theory of the social-historical around concepts such as the social imaginary, social imaginary significations, meaning, and the instituting/instituted society. An important distinction in this connection is autonomy/heteronomy, which refers to *how* a given society has instituted itself. The difference is that a society that has instituted itself autonomously *recognizes* itself as the source of its own norms and laws (*nomos*), whereas a society that has instituted itself heteronomously regards its laws as given from the outside, frequently by an extrasocial source like a god.

While other social theorists describe societies in mechanical or structural terms, as functions, structures, institutions, group interests, etc., Castoriadis's attention goes to the creative imagination. Imagination is the capacity to create new forms and significations, which is not reserved for individuals but also characterizes the social-historical. For Castoriadis, "[s]ociety is self-creation deployed as history" (1997c, p. 13). Every society in history has created itself, its own laws, norms, individual "types," and imaginary significations.

However, not every type of society acknowledges its own creative capacity as self-foundational. In fact, through history most societies have instituted themselves heteronomously, which means that they do not take responsibility for positing their own *nomoi*.

Autonomy, in this specific sense, is first of all a *project*, a project where education, in a wide sense of the term, plays a key role. This project can be historically dated to the sixth century BCE, with the Greek co-creation of democratic politics and philosophy and, again, in early European modernity. Through this cocreation – or "twin birth" – the Greeks realized, for the first time in history, that the laws (*nomoi*) of their community, the *polis*, were created by themselves and that these laws had no other, extrasocial foundation. This realization led to the appreciation of philosophical questioning, education, and very sophisticated political arrangements, but also to the realization of democracy as essentially a *tragic* regime (Castoriadis 1997a). For in a democracy – the regime of autonomy – the people realize that they are free to do "anything" and "must know that they *ought not* to do just anything" (Castoriadis 1991, p. 115).

As implied in the term *autonomy*, freedom is accompanied by the need for self-limitation. The Greeks, like the moderns, placed great value on education (*paideia*). In fact, for Castoriadis, there can be no democracy without a democratic *paideia* or individuals for whom the ethos and values of democracy has become their *own* project (Castoriadis 1997a). Individuals, in this perspective, are the walking, talking embodiments of the social institution. Indeed, for Castoriadis, the "self-institution of society" is the creation of a human world whose foremost creation is "the human individual in which the institution of society is massively embedded" (1991, p. 84). This is why autonomy is always at the same time individual and collective autonomy (for further discussion, see Straume 2008).

Contrary to what might be thought, Castoriadis' theorization of individuals via the social institution in many ways allows for a richer conception of the individual subject than the opposite (liberal) schema, where individuals are seen as more or less opposed to the social

institution. Castoriadis further distinguishes between the individual, which for him is merely a socialized specimen of a given society, and what he terms “the subject.” A subject is someone who has integrated the project of autonomy as reflexive subjectivity. According to Castoriadis: “Subjectivity, as agent of reflection and deliberation (as thought and will) is a social-historical project; its origins, repeated twice with different modalities in Greece and in Western Europe, can be dated and located” (Castoriadis 1991, p. 144). He elaborates: “This subject, human subjectivity, is characterized by reflectiveness (which ought not to be confounded with simple “thought”) and by the will or the capacity for deliberate action, in the strong sense of this term” (Castoriadis 1997b, p. 143). Such reflective subjectivity is essentially a process, not a state “reached once and for all” (Castoriadis 1997c, p. 128).

The same is true for societies, who need to institute themselves as reflexive and open in order to resist tendencies toward closure. Castoriadis states that “I call autonomous a society that not only knows explicitly that it has created its own laws but has instituted itself so as to free its radical imaginary and enable itself to alter its institutions through collective, self-reflective, and deliberate activity” (Castoriadis 1997c, p. 132). The social imaginary – or imagination when speaking about individuals – is the mode of being through which the social-historical creates and recreates itself. As the quotation shows, autonomy is exercised by a free use of the imagination, for instance, in the arts, but also in political and philosophical questioning. Thus imagination, as a creative capacity, and autonomy as *autos nomos*, combines into the self-reflexive creation that underpins the social reality as an autonomously – explicitly and consciously – instituted reality. This state is not the normal state of things, however, but a project that needs to be kept alive and vivid, through education, political activity, and a constant mode of self-questioning.

The Drift Toward Heteronomy

Most societies through history have instituted themselves as heteronomous, according to

Castoriadis. That is, they have failed to recognize – or actively concealed – the fact that they are the sources of their own laws, for example, when authorities appeal to higher forces in order to conceal their use of power and produce legitimacy (Smith 2013). Another example, frequently used in Castoriadis’ political texts and social diagnostics was the tendency to conceive social phenomena, which are created by society *tos nomos*, as if they were natural phenomena (*te fysis*), that is, as some form of natural law. Proponents of contemporary market capitalism frequently invoke such understandings when referring to the “laws of the market, the economy” etc. in lieu of democratic politics (Castoriadis 1987).

There is, in every type of organization, a general drift toward closure. This is why heteronomy is the norm, and autonomy the historical anomaly. Castoriadis refers to autonomy as a rupture of the state of heteronomy, for example, through a radical questioning that breaks the closure. In order to nurture the project of autonomy, therefore, a permanent effort is needed.

Heteronomy, as the opposite of autonomy, is about lack of freedom and lack of reflection and appeals to the myth of being as determinacy. It refers to hierarchy, conformity, and ideological veiling, especially of notions that have to do with imagination and creation (autonomy). When Castoriadis notes that the inherited philosophical tradition is unfit to conceptualize the being society of societies, this is an example of heteronomy that for Castoriadis is supported by the myth of *being as determinacy* – a myth that covers up social *doing*:

[...] the inherited way of thinking has never been able to separate out the true object of [the question of the social-historical] and to consider it for itself. This object has almost always been split into a society, related to something other than itself and, generally, to a norm, end, or *telos* grounded in something else, and a history, considered as something that happens to this society, as a disturbance in relation to a given norm or as an organic or dialectical development towards this norm, end or *telos*. (Castoriadis 1987, p. 167)

Heteronomy, in its various forms, invokes foundations outside of the socially instituted

(created) world. But there are no such foundations, according to Castoriadis. Then in lack of norms or foundations, how is it possible to justify autonomy over heteronomy? The answer, for Castoriadis, is a tautology. We have no reasons for choosing autonomy over heteronomy other than that this is a preference or choice we have made (or not made). In a certain sense, however, autonomy is self-founding, for the very criteria we use for choosing, judging, etc. were created at a specific point in history and are part of the project of autonomy itself (Castoriadis 1997b). There can be no deeper foundation or justification for why we would want autonomy than those offered by the concept itself. In the words of Castoriadis:

To the question ‘Why autonomy? Why reflection?’ there is no foundational answer, no response ‘upstream’. There is a social-historical *condition*: the project of autonomy, reflection, deliberation, and reason have already been created, they are already there, they belong to our tradition. But this *condition* is not a *foundation*. (Castoriadis 1997b, p. 394)

Autonomy in Education

Finally, what would it mean to educate for autonomy as conceptualized by Castoriadis? In order to find some answers, we need to look to social-historical situations where autonomy has been instituted as a social imaginary signification. A good case would be classical Athens, where the project of autonomy emerged for the first time with the co-birth of philosophy, politics, and democracy. This co-birth also includes the origin of Western education (Butts 1973; Jaeger 1986) and what today is called citizenship education. Various classical sources testify to how highly the Greeks valued education, *paideia*, and self-cultivation, e.g., Thucydides and the dialogues of Plato. In the latter we find numerous examples of how the educators of the day, the sophists, had discussions with Plato’s protagonist Socrates over matters of knowledge, rationality, critical thinking, argumentation, and justification or, in more general terms, on issues of questioning and truth seeking. In the democratic *poleis*,

the ability to form and justify judgments was of central importance. Greek democracy also had a special arrangement called *parrhesia*, which refers to the – institutionally protected – obligation to speak the truth in public affairs. This type of arrangements can only be realized in a society that has instituted itself as autonomous.

Education, as a social institution, sits in a certain tension between the two aspects that Castoriadis refers to as the *instituted* and the *instituting* society. The instituted society is what we normally refer to as “institutions”: structured and organized embodiments of imaginary significations such as (in our own time) schools, curriculum, classrooms, etc. The instituting society, on the other hand, refers to the creative dimension of the social institution: the aspect of society that creates itself as instituted. Another term to denote this dimension is the social imaginary or simply the social-historical. In a heteronomous society, the *instituting* society is covered over and rendered impotent by the instituted (cf. the notion of closure). Education in a modern society relates to both aspects: it takes care social reproduction, but has also been a site for renewal and sociopolitical reform. However, as history shows, education can easily be turned into *schooling* as mere social reproduction: unreflective practices that are unable to question and transform themselves in relation to aims and purposes. Contemporary phenomena such as “learnification” (criticized by Biesta 2006) and “the entrepreneurial self” (Simons and Masschelein 2008) are clear examples of heteronomy.

In order to break the closure of heteronomy, following Castoriadis, questions about education must be put in normative terms: is the kinds of education we have the ones that we ought to have? What does it mean to educate well, and why should we do it? This problematizing questioning never stops, in the regime of autonomy, and the answers given can never be the final answers. Nevertheless, it is important, in line with the project of autonomy, to create the laws and norms that we want to regulate and orient our life together. In the words of Castoriadis: “When I say that the Greeks are for us a germ, I mean, first, that they

never stopped thinking about this question: What is it that the institution of society ought to achieve. And second, I mean that in the paradigmatic case, Athens, they gave this answer: the creation of human beings living with beauty, living with wisdom, and loving the common good” (Castoriadis 1991, p. 123).

Cavell and Philosophy of Education

Michael A. Peters

University of Waikato, Hamilton, New Zealand

Introduction

Stanley Cavell is an American philosopher who, following Wittgenstein, teaches us how to read Wittgenstein and practice philosophy in post-analytic philosophy (Mulhall 1994). He speaks directly to philosophers of education through his treatment of the figure of the child and “the scene of instruction” in Wittgenstein’s (1972) *Philosophical Investigations*, addressing “the education of grown ups” (Saito and Standish 2012) and in works like *Themes Out of School* (Cavell 1988).

Stanley Cavell is an American philosopher, who with others like Richard Rorty – though in very different ways – has deliberately attempted to

heal the epistemological rupture in the tradition of American public thought caused by a Viennese analytic strain of philosophy. Cavell has done so by returning to the origins of American philosophy represented in Emerson's transcendentalism and Thoreau's "Walden" (see Cavell 1981a, 1981b, 1989, 1990, 1994). On this reading the American intellectual tradition was fractured at the point that a group of Mitteleuropean, and mostly Jewish, thinkers (e.g., Rudolf Carnap, Herbert Feigl, Carl Hempel, Hans Reichenbach, and Otto Neurath) – who were a part of the Vienna Circle – migrated to the United States to escape persecution by the Third Reich. Willard van Quine himself, as a key figure in the second wave of analyticity and the father of American postwar philosophy, spent some time in Vienna in the early 1930s (see Borradori 1994).

As a neoromantic or neo-transcendentalist, Cavell – uncharacteristically for his generation – also revitalizes this American tradition by openly engaging with other disciplines and with the leading figures of contemporary continental philosophy. (Perhaps, he shows a greater propensity to interact with French post-structuralists and psychoanalysts than he does with members of the Frankfurt School and Jürgen Habermas or with contemporary representatives of continental hermeneutics.)

In one sense he represents the future of American philosophy: someone who is sympathetically schooled in American transcendental and pragmatist strands of thought; someone who provides a "model" of post-analytic philosophy, based upon a range of different media, compositional forms, and genres; someone who willingly acknowledges the diversity of philosophical traditions and plural readings of a text; and a philosopher who, keenly aware of his native tradition and its European influences, is prepared to speculate not only about the meaning of "American" but also the meaning of "philosophy" in new and interesting ways. Cavell's uniqueness as a philosopher is evidenced by his capacity to write across a range of topics and mediums (see his Shakespeare and film criticism: Cavell 1977, 1979, 1987a, b, 1996a) and by his approach to philosophy. Cavell is a philosopher, one of the few within the analytic

tradition (if we still regard both Austin and Wittgenstein as somehow part of that tradition), who embodies Rorty's (1991) notion of "philosophy as a kind of writing." Certainly, like Derrida in respect to philosophy itself, Cavell regards philosophy as a set of texts to be worked through rather than a set of problems to be addressed.

It is certainly for these reasons that philosophers of education ought to read Cavell. In this sense his philosophical career provides a reading of the possibilities of analytic philosophy when it is practiced creatively alongside other disciplines and traditions. This tendency became evident early on in his career beginning with his now classic "Must We Mean What We Say?" (Cavell 1969). Cavell not only provides this "model" of transition or transformation but also displays very strong understanding and commitment to ordinary language philosophy and to certain analytic texts, particularly those of Austin and Wittgenstein. In particular, his interpretation of Wittgenstein distinguishes him as a contemporary philosopher, as someone who knows how to practice or "do" philosophy in an age of uncertainty (see Peters 1999; Peters and Marshall 1999), and as someone who, through his interpretation of Wittgenstein, speaks to philosophy to education. Even though he never directly addresses such an audience or community directly, the terms and titles of his work reflect a sensitivity to and a respect for questions of pedagogy and its place in philosophy, not just the metaphor of school in "Themes Out of School: Effects and Causes" (Cavell 1988) but genuine attention to the Wittgensteinian figure of the child in philosophy and the Wittgensteinian themes of learning a language and a culture.

The reasons why he ought to be read in this way lie, at least in part, with his own appraisal of Wittgenstein's work, particularly the *Investigations*, but also on his interpretation of Wittgenstein's historical place within the so-called analytic tradition. Cavell attempts to rescue an "aesthetic-ethical" Wittgenstein, contextualized in a European intellectual milieu, located at the intersection of romanticism and skepticism, and in relation to the question of modernism in the arts. Above all, he emphasizes Wittgenstein as a man who lived his

philosophy – philosophy as a way of life – and Wittgenstein as someone whose philosophy is impossible to understand without understanding the man and whose style is aesthetically speaking central to the meaning of the Investigations.

Cavell's (1995b) "Notes and Afterthoughts on the Opening of Wittgenstein's Investigations" (referred hereafter to as notes) might be taken as a prime example of Cavell's call to philosophers of education. Cavell's reading provides a basis for a Wittgensteinian pedagogics: not only does it hold up the figure of the child as central to the Investigations, but it does so in a philosophical style that, though distinctively Cavell's own, comes closest to the spirit of philosophizing in Wittgenstein's sense. The text of the Investigations is, itself, an exemplary pedagogical text showing us how to do philosophy in a new way. Cavell's notes provide us with the rare opportunity, as Michael Payne (1995, p. 5) argues, "of witnessing Cavell in the act of teaching a philosophical text." Cavell (1995a, p. 126), himself, directly addresses this issue when he indicates that part of the reason for publishing the notes was that some who had attended his lectures suggested that they would be of pedagogical help; yet he also says "There is still, I believe, no canonical way of teaching the Investigations."

Another reason why we might focus on this text is because Cavell's notes formed the basis of a course he gave on the Investigations at Berkeley in 1960, which were later amplified and developed at Harvard where he gave lectures based upon them some half a dozen times during the 1960s and 1970s. In other words, Cavell chooses to adopt the genre of "notes" – a form which Wittgenstein favored – to explore the way in which subsequent readings he gave of Wittgenstein informed his career over a period of almost 40 years. It is an interrelated set of readings dominated by the teaching of Wittgenstein. Cavell (1996c, p. 369) writes of that period:

That first time around, I presented it [the Investigations] as what I called a modernist work, meaning to say that its incessant and explicit self-reflection struck me as unlike the self-consciousness of any other undoubted work of philosophy I knew. I did not then take the cue

to ask whether, or how, or to what extent, philosophy on the whole can escape issues of modernity.

He gave the last set of lectures based on notes, which had undergone further development, especially in light of his "The Claim of Reason," in 1984. In 1991 he had occasioned to make a presentation that included both the notes and his afterthoughts concerning them, but it was not until the spring of 1993 that he began to recall his earliest thoughts on the Investigations. The final version appears in "Philosophical Passages" (1995b) and also in Hans Sluga's (1998) "The Cambridge Companion to Wittgenstein." The notes therefore are central to Cavell's interests and his development: it is an exemplary Cavellian text.

The notes themselves appear in italics in the text and Cavell's afterthoughts appear in a standard upright font. What we are presented with is a lengthy essay of some 59 pages that comprises Cavell's reflections over at least 30 years and a text that resembles Wittgenstein's own manuscripts in the complexity of its composition: a set of remarks worked and reworked, interspersed in a variety of typefaces not only with the original notes and afterthoughts but also with extensive quotations from his earlier works, from a number of other authors (including Augustine, Hume, and Foucault) and, in addition, references to both traditions the so-called Anglo-American tradition (e.g., Emerson, Austin, Kripke) and the continental (e.g., Nietzsche, Heidegger, Derrida).

The result is a rich textual layering that presents the reader with an elaborate, labyrinthine structure echoing the process of Cavell's thinking – a kind of spatialized conceptual mapping or architecture – which at one and the same time utilizes some of the gestures of Wittgensteinian philosophizing the incessant questioning, the rhetorical flourishes, the thought experiments, the same tentativeness in suggestion and yet boldness in concept, and the poetizing interpretations. This has led some critics, including Anthony Kenny, Mary Mothersill, Anthony Palmer, and M. Glouberman, to comment negatively upon his "self-indulgent style," while others, perhaps more attuned to Cavell's project, talk of "the

philosopher as novelist” or suggest that Cavell is developing “a new kind of storytelling” unlike Michael Wood, who commenting on *The Claim of Reason* remarks “The writing is remarkable here, the philosopher as novelist gives density of detail to fleshless old questions” and suggests that Cavell’s “anecdotes, scenarios, little parables, and exemplary stories are better than most novelists” (cited in Fischer 1989, fn 6, pp. 144–145). In Cavell’s work we find a new kind of practicing philosophy that involves a textually self-conscious and narrative experimentalism.

Cavell (1996c, p. 370) suggests that, motivated by his reading of Nietzsche, Heidegger, and Derrida, it was only in his most recent rethinking did he begin “to move more systematically toward an articulation of Wittgenstein’s manner, the sheer sense of deliberateness and beauty of his writing, as internal to the sense of his philosophical aims.”

Cavell’s work as a whole is concerned with the finding or recovery of the human voice and of finding one’s own voice. In “The Melodrama of the Unknown Woman: A Reading of *Gaslight*,” he talks of “reinserting or replacing the human voice in philosophical thinking, that voice that philosophy finds itself to need to deny,” and in “The Philosopher in American Life,” he suggests that logical analysis has suppressed the human voice – the voice that ordinary language philosophy aims at recovering. Cavell (1996c, p. 381) himself writes:

Part of my sense of the Investigations as a modernist work is that its portrait of the human is recognizable as one of the modern self or, as we are given to say, the modern subject. Since we are considering a work of philosophy, this portrait will not be unrelated to a classical portrait of the subject of philosophy, say that to be found in Plato’s *Republic*, where a human soul finds itself chained in illusion, so estranged from itself and lost to reality that it attacks the one who comes to turn it around and free it by a way of speaking to it, thus inciting it to seek the pleasures of the clear light of day.

Stanley Cavell received his AB in music from the University of California, Berkeley, and his PhD, in philosophy, from Harvard. He taught at Berkeley for 6 years, before returning to Harvard

in 1963, where he became the Walter M. Cabot Professor of Aesthetics and the General Theory of Value. He became professor emeritus in 1997.

Introduction

To make a claim that postmodern education can be associated with Stanley Cavell's (1979) work would require that one analyzes what Cavell means by education. And a Cavellian understanding of education cannot be far removed from his claims about philosophy, as the way he understands philosophy would reveal some of his thoughts on education. More specifically, Cavell (1979: 384) claims that an individual stands in relation to herself and makes herself "intelligible to others ... [in her] capacity to present ...

[herself] for acknowledgement" (Cavell, 1979: 393). So, as in a postmodern view of education, an individual acknowledges herself and engages with others in a relationship in which she and others "experience" one another "endlessly" and "continuously" (Cavell, 1979: 441). Cavell (1979: 440–441) offers two justifications for education: first, one engages "afresh" with other human beings, such as "conceiving the other from the other's point of view," and whatever one wants to know about others, "one first has to find in oneself and then read *into* the other." Such a view of education is starkly different from the view cogently criticized by Gert Biesta, by which individuals acquire "a clearly defined set of knowledge, ideas and values" (Biesta, 2003: 62) and by which an individual exclusively cultivates her own "rational autonomy" (Biesta, 2003: 64). Instead, a Cavellian understanding of education is one whereby an individual uses her autonomy in relation to others, in particular experiencing them without any precondition of finality – that is, the educative experience in itself remains incomplete and in potentiality. The very idea of looking at human engagement "afresh" is a vindication that the educative experience is always potentially in relation to some sort of "appropriateness ... without knowing everything about it" (Cavell, 1979: 442–443). Likewise, when humans engage, they remain "imperfectly known" (Cavell, 1979: 444) to one another, as there is always more to know about one another on the basis that human conscience is "not generally conclusive" (Cavell, 1979: 431). And, if they were to be perfectly known to others – a view rebuked by Cavell – their education would have come to an end.

This brings one back to the point raised earlier, namely, that understanding Cavell's use of philosophy has some bearing on his understanding of education. For Cavell, doing philosophy implies analyzing "texts" (Cavell, 1979: 5). These "texts" include written and oral texts on human lived experiences that they (humans) are engaged with/in ordinarily, such as when one identifies what is familiar and also what is strange in the texts and, by implication, also include an analysis of relational human lived experiences (Davis,

2010: 161). For Cavell, explaining human relations in terms of both strangeness and familiarity is to invoke the criterion of judgment according to which people's encounters with themselves and others are assessed. In my view, such an understanding of philosophy would not just give us knowledge of what texts mean but also insight into the human (im)possibilities that shaped the texts. And, considering that strangeness in itself points to uncertainty – that is, the possibility that we do not always know with certainty (Cavell, 1979: 46), an examination of education in relation to skepticism is necessarily educed. Put differently, a Cavellian understanding of education has to do with what it means to act with skepticism, that is, what it means to engage with the familiar and simultaneously being open to what might yet come (meaning what can be conceived as strange). The author now examines more closely the relationship between a Cavellian understanding of skepticism and education.

Education and Skepticism

Educational encounters among human beings enacted within a space of skepticism can be explained as follows: Human beings, in relation to one another, “do not know with certainty of the existence of the external world (or of other minds)” (Cavell, 1979: 45). Cavell draws on Wittgenstein to explain that human relations in the world “[are] not [relations] of knowing, where knowing construes itself as being certain” (Cavell, 1979: 45). What we know of other human beings is how they present themselves to us. In other words, skepticism brings into question the notion of “knowing” others completely, because we only know on the basis of others' behavior. And, if they do not present themselves to us in an encounter, then we cannot claim to have knowledge of them. Human beings might suffer a loss of life or some form of indignation. We would only know their affliction on the grounds of what they inform us of or present us with, as “we cannot have their sentience, say literally have a pain of theirs” (Cavell, 1979: 46). In this way, education, as an enactment of

human encounters, is inherently skeptical, because if we cannot know others completely then we invariably engage with them as “strangers” (Cavell, 1979: 443). Cavell makes the point that one can know the age, height, gender, color, and language style of a person, but this does not imply that one actually knows him or her. Put differently, educational relations, following Cavell (1979: 444), involve strangeness in the sense that one is always “imperfectly known” to others. By implication, education requires a willingness on the part of humans to be in communication with one another (Cavell, 1979: 47) and that such communication is never directed at achieving finality, for that in itself would imply that the possibility for strangeness would dissipate and therefore that humans could live in isolation from one another. If one does not remain “imperfectly known” to others, then the possibility exists that one might be “perfectly” known to them and hence strangeness would cease to exist. Similarly, if finality in human encounters is the aim of communication, then, equally, the isolation of humans from others would be possible because education would have concluded. In other words, if communication comes to an abrupt end, the possibility of engaging in human encounters would be thwarted and education would have reached conclusiveness. Instead, education requires continuous engagement with others without the possibility that human encounters would culminate in something conclusive, for that would mark the end of strangeness and, as a corollary, the expiration of education. If this happens, human encounters would attain closure and, as aptly put by David T. Hansen, a reflective “openness to the new” (Hansen, 2011: 7) would no longer be possible. Put differently, a Cavellian stance on education does not debunk an openness to what is strange or surprising, neither does it perpetuate that human encounters should be about “grasping final truths that one can trumpet to others” (Hansen, 2011: 117). Rather, in cultivating one's own truth claims in relation to others' understandings of truth, we aspire to “inhabit” or “dwell together” in the world (Hansen 2011: 113). Cavell (1979: 440) offers a succinct description of enacting our skepticism educationally:

In saying that we live our skepticism, I mean to register this ignorance about everyday position towards others – not that we positively know that we are never, or not ordinarily, in best cases for knowing of the existence of others, but that we are rather disappointed in our occasions for knowing, as though we have, or have lost, some picture of what knowing another, or being known by another, would really come to – a harmony, a concord, a union, a transparency, a governance, a power – against which our actual successes at knowing, and being known, are poor things.

Thus, education as skepticism is about leaving things “open” and inconclusive – a matter of encountering humans “in the face of doubt” (Cavell, 1979: 431). In other words, individuals in relation to other individuals are strangers who do not turn a blind eye to doubting themselves and others as if there is nothing more to deliberate about, where the “intersection of the strange and the familiar, the surprising and the unexpected” (Hansen, 2011: 86) is no longer possible. In this way, an enactment of skeptical human encounters is always in “becoming through the experience of reflective openness to the new fused with reflective loyalty to the known” (Hansen, 2011: 86). And when human encounters are grounded in a receptiveness to the new without unjustifiably negating the familiar, such encounters not only resonate with what is strange, but would be highly charged towards showing one’s skepticism towards others and, in turn, others’ skepticism towards one. As cogently put by Cavell (1979: 47), to live educationally is to do so skeptically with respect to others, which involves “to penetrate or be penetrated by another.” In other words, educational encounters are constituted by the human capacity to understand, listen to others, and learn from them – a matter of remaining open to the unexpected, surprise, and that which is not yet. Consequently, as mentioned earlier, education is not exclusively about knowing the other in relation to oneself. Rather, education involves engaging the other in relation to oneself, with the possibility that one experiences the other’s otherness without claims to getting to know the other. Such a situation is not justifiable and desirable in a Cavellian notion of education. In any case, what one comes to know of the other

depends on what the other shows. As aptly put by Cavell (1979: 443), “[a]ll anyone knows or could know is what I am able to show them of myself.” And, as Maxine Greene (1995: 43) so eloquently reminds us, showing oneself in communion with others is “always incomplete because there is always more to be discovered and more to be said.” Quite pertinently, education is about human encounters that stir people “... to wide-awakeness, to imaginative action, and to renewed consciousness of possibility” (Greene, 1995: 43). Education is not distinctly about “perfectly” knowing this or that.

Education and Answerability

Now, if education cannot be about knowing others perfectly, for that is neither possible nor desirable in a Cavellian sense, then at least human encounters between self and others still involve some form of acknowledgement. However, as has been argued for thus far, it is not an acknowledgement inspired by the intention to know others, but rather an acknowledgement of others on the basis of what is common within other human beings and ourselves. And what is common in ourselves and other humans is the humanity that lies in us. As stated by Cavell (1979: 443),

[there] is a surmise that another may be owed acknowledgement simply on the ground of his humanity, acknowledgement as a human being, for which nothing will do but my revealing myself to him as a human being, unrestrictedly, as his or her sheer other, his or her fellow, his or her *semblable*.

For Cavell (1979: 438–439), acknowledging humanity in ourselves and others involves being answerable to them through caring for others and being committed to them justly. At the core of such a Cavellian understanding of education is the practice of justice towards others – a matter of others being “owed some unrestricted revelation of my humanity” (Cavell, 1979: 440). And, in exercising one’s humanity towards others, one acknowledges and respects others’ cultural differences without being overtly dismissive of such cultural variability. Treating others justly, that is humanely, involves acknowledging others as

human beings whose differences are not reasons for exclusion, marginalization, rebuke, or hatred on the basis that others' forms of living – their values, beliefs, hopes, and aspirations – are deemed irrelevant, other, and unworthy of recognition. Rather, just or humane treatment of others involves talking with others, listening to them, interacting with them in deliberative ways, and treating them with dignity and respect – a matter of acknowledging or conceiving “the other from the other's point of view” (Cavell, 1979: 441). Thus, for Cavell, education is not concerned with which norms and practices are valid for all human beings everywhere, but rather how, in solidarity, we can reach decisions about ourselves and others that would be deemed just and an acknowledgement of our humanity. Seyla Benhabib (2011: 129) supports such a view of education, one in which “complex processes of public argument, deliberation, and exchange through which universalist claims are contested and contextualised, invoked and revoked . . .”.

Education and Risk Taking

Cavell's (2004) *Cities of words: Pedagogical letters on a register of the moral life* articulates his conception of education in relation to pedagogical encounters “in the classroom.” For him, education is the act of lodging a demand or “desire for reform or transfiguration of the world . . . [where] we feel ourselves called upon for change . . . a condition in which the good city we would inhabit cannot be constructed, since it exists only in our intelligible encounters with each other” (Cavell, 2004: 2–5). And when we act educationally upon the world, we do so with deep “suspicion,” “distrust,” and with “risking impertinence” (Cavell, 2004: 6–9). The author's interest is in Cavell's insistence that education is inherently characterized by taking risks, which he explains in relation to reading texts so as to ensure surprises for the self, as new thoughts occur and new arrangements are more suitably brought into view (Cavell, 2004: 15). The notion of education as risk taking is explained by Cavell (2004: 18) as human action, whereby

one's quarrel with the world need not be settled, nor cynically be set aside as unsettlable. It is a condition in which you can at once want the world and want it to change – even change it

In a way, education that relies on taking risks is aimed at cultivating new “rebeginnings,” what Hannah Arendt (1958: 246) refers to as starting new and unending processes of human action “in the ever-recurring cycle of becoming.” In other words, when people act upon the world, they interrupt it and begin something “unpredictably” new (Arendt, 1958: 244–246). Put differently, risk taking is one of the potentialities of human encounters, in other words educational relationships. Education constituted by risk taking shows a greater sensitivity towards, incalculability of, and unpredictability of the chaotic uncertainty of the future (Arendt, 1958: 237). Human beings who take risks are prepared to change their minds and start afresh; they are not constrained by human action that is closed to the unexpected, the lucky find. For this reason, Cavell (2004: 3) avers that practicing philosophy (and education for that matter) “is to lead the soul, imprisoned and distorted by darkness, into the freedom of the day . . . that would secure a human settlement with the world that goes beyond human sense and certainty.”

Summary

In this entry, the author has given a postmodern account of education in relation to the seminal thoughts of Cavell. In the main, the aforementioned Cavellian understanding of education breaks with enlightenment views of education as a universalist conception of education that makes assumptions that education should serve a dominant culture. Rather, a Cavellian understanding of education is sensitive and open to different cultural traditions. Likewise, it has been argued that education does not abandon autonomous human action, but rather views the autonomy of the self in relation to others' autonomy. In other words, following Cavell, understanding the self in relation to others invariably results in an enriched view of self and others, in which human encounters are

informed by a radical questioning of our deepest assumptions (Arcilla, 2003: 141). Finally, a Cavellian understanding of education encourages forms of communication by which human beings take risks to cultivate unpredictable, unimaginable, incalculable encounters through which they can justly and humanely change the world.

This entry concerns ruptures and continuities in the modern Western child as it shifts from what is now called natural philosophy to political philosophy to psychology, a shift which enabled developmental psychology to become the dominant discipline for inscribing the child in educational discourse over the twentieth century.

In Sight and Out of Mind: Descartes' Child

And here the first and principal cause of all errors can be recognized. For in childhood, our mind was of course so closely bound to the body that it did not apply itself to any thoughts other than those by means of which it was aware of those things which affected the body: and it did not yet relate

those to something situated outside itself; but merely felt pain when something disagreeable occurred to the body; and pleasure when something agreeable occurred (Descartes 1983, p. 32, art.71).

For Descartes (1596-1650), the first and principal of all errors (in arriving at Truth) lay in a near mind-body fusion inscribed as an obviousness of childhood. Children did not move their thoughts beyond bodily sensation and could not attribute sensations to “something situated outside itself.” For there to be an analytical space called “outside” to which a child was incapable of making an appeal, there had to be a perceiver aware of such distinctions and able to patrol the borders. The Cartesian perceiver was an adult mounted on a pivot, a turnable knower who, like its early Christian counterpart, e.g., Augustine’s, could see both within and without. What is “outside” in a Cartesian epistemology is complex and perhaps best illustrated by what was no longer outside post-Scholasticism.

Unlike Platonist traditions, Descartes did not accept that the World was an ontic logos which was already meaningfully embodied in the correspondence between the form of things. He did not accept that moral order and vision of the Ideas were unavoidably synonymous because for Descartes there were no Ideas in the Platonic sense. Once cosmic order was no longer seen as embodying either the Platonic Forms or Aristotelian species and forms that which lay outside the early Christian “inner man” had to be rewritten.

This rewriting saw the external as an extended substance, “World or Universe.” The human body marked the judicial horizon between interior/exterior realms. The World as extended substance did not hold pre-existing Ideas and Goodness that one journeyed through the inner man to arrive at. Aspects of the whole were not borne into the parts and the integrity and meaning of the parts did not carry forward to become an integral part of the whole. The body and the World were quantities open to theorization as to what they did or did not hold or as to what laws structured them.

Exterior and interior realms were not homologous a priori forms although the exterior existed by virtue of what “ideas” humans could have of it in the mind. Interiors (e.g., mind and the processes of reason) and exteriors (body/World) were separately identifiable substances with different principle attributes that made them so.

One gained certainty and Truth about the exterior World only when one subjected bodily sensation or the everydayness of personal embodiment to rigorous standards for evidence. The standard or norm for Truth now lay within the procedures themselves, not on a shelf waiting for the person to turn toward it. Conformity to the method would secure the substantive Truth that would be the outcome and conformity to the correct order of thought now constituted “reason.” Reason was no longer a vision of order but the order for arriving at a different vision, a disengaged and disembodied one that took distance from bodily sensation and the immediacy of the “empirical” World as its benchmark.

The outside for Descartes did not dismiss Godly omnipotence even though humans were now admitted to constructing and deductively verifying the terms of His brilliance. God was the original divine authority and constituted the greatest certainty of all but in a crucial shift there was “in those matters about which divine faith teaches us nothing” space for a method that would establish the Truth beyond a bodily sensation. The advent of matters about which divine faith teaches us nothing was pivotal to the Cartesian cogito. Adults, i.e., humans, could make the interiority of thought present to itself without an ontic logos and yet with the continued presence of God because there were matters about which divine faith did not instruct. Discursive space for controlling the resolution of doubt (now “scientific” rather than “confessional”) had been opened to human conjecture and it was the rigorous Cartesian method toward clear and distinct ideas that indicated the uptake of that opening. Humanity could understand itself not just in terms of being a mirror of God’s image or just as an effect of a spiritual entity but as the source of its own effects as well. Conformity to the correct methods for discerning truth was necessary because other

methods had the potential to lead humans into erroneous judgments about the best choice to make. Cartesian rationalism required at a crucial juncture the failure of faith in divine matters to instruct in everything and the possibility for failure in human method. Descartes' resolution for the possibility of imperfection was the procedure for certitude that he called reason. It is in his obsession with procedures, and with the earth's motion as an inciting object of analysis, that the child and childhood were given meaning as error personified, that is, as the bodily magnified.

The rejection of Scholastic teachings saw a rejection of Aristotelian binaries of natural and unnatural Beings, of natural and unnatural motion, of celestial and terrestrial bodies. Beings were not categorized according to an innate potential to actualize as something we might understand almost as its opposite. Nature was not variegated at the level of "matter" or "essence" insofar as matter had been given a universal nature and assumed constitutive of all Beings. For Descartes and for Newton after him, this appeal to matter as universally composing all things meant that all extensions (bodies) could become subject to the same laws of motion.

The rewriting of matter and the mechanization of the cosmos enabled a different kind of wedge to be driven between "mind" and "body" than in Platonic and early Christian theology. In presenting the human body as extension and as subject to forces beyond its control, the mind was generated as a space free from the banal everydayness of particle/force interactions. The mind could become the new perceiving locus of reality and it was within this locus that reason's movement could operate and therefore operate to exclude the child from that which it helped to construct.

Reason did not just operate to divide children from humans but to divide the subject internally. To be distant from one's body via the correct procedures for coming to certainty was to establish the Cartesian process called reason, a process which made "subjective" space objective and which reorganized empirical sensation into different meaning. The mind's ability to travel beyond

the body's physicality was thus reason's requirement. And it was all the more so because what belonged to "our nature" and what one came to know first was mind. "The faculty of thinking" was "known prior to and more certainly than any corporeal things; for we have already perceived this [thinking], and yet are still doubting the rest" (Descartes 1983, p. 5, art. 8).

To rewrite reason in this way was to provide the pathway for a circular consciousness that has subsequently been rallied as the epitome of a metaphysics of presence. Human beings were considered human because we were capable of moving without running; the mind could evade what the body urged it to believe. The inscription of reason as a distance from bodily sensation secured the (analytical and physical) space necessary to view something (conceptually) as a movement, a move beyond or away from something else. It was movement to a point from which the mind could then spin back and view where it had once erroneously been as a child (i.e., close to the body) that would suggest reason's presence. Reason was no longer the uniform circular motion of the divine aspect of the universe. It was a metaphorical and analytically linear movement away from possible erroneous bodily sensation. Humanity's presence to itself was thus inscribed into a concept of mind-body distance via physics. Without distance, movement, space, and time that structured the procedures for certitude one could not become conscious of one's humanness, one was without reason, was not fully human, and was therefore a child.

Locke and Rousseau's Children

John Locke's (1632-1704) acceptance of what is now called empiricism does not generate the same textual use of the child as Descartes and nor does it indicate that he meant the same thing by reason. The Lockean child depicted in the letters comprising *Some Thoughts on Education* was intimately and analytically bound to the texts now treated as political philosophies and epistemologies, i.e., *Two Treatises of Government* and the *Essay*

Concerning Human Understanding respectively. In the *First Treatise*, the child, particularly the boy, and his place in the family relative to the patriarch are the objects on which a new kind of Utopian civil society predicated on a social contract is carved out. Arguing against Sir Robert Filmer's *Patriarcha, or on the Natural Power of Kings*, Locke recommended a form of social organization based on democratic elections in which men would give up some of their powers in order to belong to a civil society which secured their freedom (where freedom meant conformity to the laws of a civil society which protected one's life, liberty, health, and property).

Within the ideal family for Locke, the child's treatment is based on contract-like arrangements. Locke attributes the child with a Willpower that is on its inside and because the child is now given possession of its own internal powers that have Newtonian motive and resistive qualities, it is problematized as one who must be dealt with in a particular way. If the child is to become the kind of English gentleman that Locke would like to see inhabiting his ideal civil society then the question remains as to how to have a new human join in a social contract which it did not initially authorize. Parents and tutor, the sources of education for Locke, must reason with a child and use explanations pitched to its level of understanding rather than whip or beat a child into submission. This is because parents do not possess the child even though they have temporary authority over their offspring. In return, the child has a duty of obedience to the parents for protecting and feeding it – the contract writ small in the home. In order to raise a child, then, parents must first bend the child's Will early, i.e., deal with its inherent powers rather than any notion of its original sin. If an infant cries, it is expressing its Willpower and if parents give into unreasonable demands that the infant is making through such cries then they are creating the kind of man who loves dominion and who cannot sustain self-denial. Therefore, through a system of permissions and denials called health the infant is prepared early through the treatment of its body for becoming a reasoning gentleman, i.e., one who can eventually discern between those desires and

impulses that it would be gentlemanly to honor and those that it would not.

Because education makes all the difference between men for Locke, the child undergoes formal tutoring that is less concerned with what is today thought of as subject matter recall and more with a quality that Locke calls "vertue." Reason has a moral inscription and the equivalent of the curriculum is to facilitate vertue's development through gradually preparing different faculties of mind for reason's full unfoldment. Rather than rote Latin lessons, for instance, the child learns, i.e., gains a stock of Ideas which it is in a natural condition to differentiate, by "experience" which is all the interactions with things, with others, with books, and with symbols that will be encountered over time.

Unlike Descartes' child, the Lockean one was admitted to being human and to having consciousness, i.e., awareness of that humanity. This is because for Locke the child was not the bodily magnified and the human body admitted of fact. We receive Ideas through the power of objects acting on our sensory mechanisms. These are natural events and therefore outside claims to truth or error. Whereas Descartes' body was inherently sinful and could not be considered a site of knowledge, Locke's body was the first positive step to the formation of different kinds of knowledge that he explicates in the *Essay* (i.e., intuitive, demonstrative rational, and sensitive knowledge). This different orientation to human body, to powers, to learning, and to reason allowed a different inscription of the child and announced what is thought of today as its modernness (Baker 2001).

Jean-Jacques Rousseau both drew on and departed from Locke's delineation of the child. In the tradition of high romanticism, Rousseau's child is assertively modern and countermodern. Rousseau's imaginary orphaned character called Émile in the novella, *Émile, or on Education*, who is tutored through to manhood is again made legible by a wider political philosophy and prescription for Utopia (e.g., *First and Second Discourses*). As for Locke, Rousseau writes a counter-memory to human history. He does not rely on the Biblical tale in Genesis to explain from whence humans, and different kinds of

humans – natural, savage, and civil Man in Rousseau’s words – came. Rousseau’s hypothetical history of human nature as it has ended up and evidenced itself in civil society slaps present-day notions of progress in the face; the evolution of the species toward life in civil society is a form of disintegration, hence natural and savage states are held up as ideal and civil man as degraded, dependent, torn between dueling realms of spirit and matter, embroiled in unequal power relations, and therefore far removed from what was natural in the past.

This produces a different kind of child amid a different version of the social contract. Rousseau’s child is given possession of a Will, but not of power for power in what might be thought of as its social forms (including sexual and mental kinds) is a commodity and an artifact of human evolution out of a state of nature. When an infant cries for Rousseau it is expressing its Will, not its power as for Locke. It will learn social power if the adults around it give it what it wants. Just as in Rousseau’s *Social Contract* the Will of the people is distinct from the executive, the government, so, too, is the child’s Will made distinct from its ability to do anything about it. The having of Will does not mean the having of power to execute it. Rousseau’s child is therefore subjected to a different kind of education-for-reason and morality. It is a form that does not assume that the child has any initial ability to reason and rational explanations are thereby discredited. Instead the tutor, especially during childhood, must set up situations in which the young Émile must come to the realization of something for himself or so it seems for “doubtless your pupil should do only what he wants. . .but he ought to want only what it is you want him to want.” Émile is often led to believe one thing only to learn the lesson of the opposite, a lesson communicated through interactions with self, with things, and eventually with others that relies less on sermons and more on active involvement in seemingly random situations. Thus the different inscription of power as an executive tool, its separation from Will in the child, and the lack of reasoning ability attributed to the young writes its education differently.

From Mathematical to Developmental Psychology

Johann Friedrich Herbart (1776-1841) was one of the earlier theorists to depart from the Faculty Psychology reminiscent of Locke and Rousseau toward mathematical psychology. He argued, in a noticeable departure from his predecessors, that a child was not born with a Will and that there were no such things as separate “Faculties” of mind (Herbart 1804/1977a). Mind was a single entity and the Will, feelings, and desires were made via “presentations” to the child’s consciousness, preferably those organized by the family tutor. Objects in the exterior world and the interior mind possessed souls or powers. These “Reals” in the world which had their own powers clashed like Newtonian forces and each Real tried to self-preserve its soul in the process. The outcome of such perturbations was mathematically calculable; the stronger would win out and remain above the “threshold of consciousness” and be stored in memory, a threshold that unwittingly became a precondition to Freud’s future rendition of the child and its subconscious. What resulted for Herbart were ideas and a large, increasing stock of ideas called an apperceptive mass. The aim of education for Herbart was morality and amid the narrative tropes of the German *Bildungsroman*, an emergent Prussian nation-State, and a reaction against Kantian idealism, the child would be built out of systematically screened and organized presentations chosen by the tutor. In an ever-increasing upward spiral that signaled a move toward “civilization” and away from the signifier of “barbarism” the child’s five internal relations of the Will would be constructed to stand in good alignment with each other. Thus, both mind and Will would be built and the widened circle of thought that resulted, which was comported from diverse stimuli, would be the precondition to a stable, homogeneous, and consistent identity required by the intuitively moral man.

By the early 1800s, therefore, it was possible for Herbart to disarticulate philosophy from psychology, ends from means, and thereby to assert that pedagogy was a distinct science (Herbart

1806/1977b). Pedagogy was that science focused on the act of instruction and it was intimately interrelated with other sciences, specifically that branch of aesthetics he called ethics and the study of consciousness called psychology, where psychology was not experimental but calculable and related to the observation of the young and an estimation of which presentations they had already been exposed to.

By the late 1800s, psychology was raising different questions regarding the “development” of humans than those posed earlier by Herbart in Germany and was beginning to “experiment” with experimenting (Herman 1995; Taylor 1994). Psychology had begun to make use of scientific methods of observation and aggregation of data to investigate problems like Will in children, criminality in adults, delinquency in juveniles, and degeneracy in “races.” Methods drawn from physical anthropology, statistics, and medicine infused the research techniques of the first generation of self-proclaimed psychologists such as Granville Stanley Hall (1846-1924).

Education’s uptake of psychological methods for posing and answering questions was also facilitated by an appeal to science as a means for truth production. In the late nineteenth century, the New Scientific Pedagogy and the New Psychology were often synonymous terms in educational discourse and were deployed rhetorically to assert a truth claim. The interdependency of education and psychology was enabled by education’s provision of the subjects (e.g., children) necessary for data gathering and by psychology’s production of new strategies for monitoring and changing those subjects (e.g., teaching techniques). It was partly because of an institutional and intellectual interdependence that developmentalism could take hold, creating a new kind of “developing child” through techniques of study that emerged in/as a variety of public school reform efforts.

Some developmental theorists such as the radical branch of German Herbartianism emphasized the “ontology recapitulates phylogeny” argument, suggesting that children develop in stages marked by the evolution of “the race” and that this was primarily a genetic unfolding. Others, like the American Herbartianists, reinscribed the child’s

Will as inborn and not built, thereby positing development more singularly as a widening of the child’s circle of thought rather than as a form of implanting Will. Still further, Froebelians [proponents of Friedrich Froebel (1782–1852) and the kindergarten movement] focused on very young children particularly within the context of the family and preschooling and did not assume that scientific observation of a child was necessary to helping a child “develop.” In sum, development did not mean one thing, but developmentalism was a wide variety of movements which converged around a belief that the child did in fact develop through set stages (e.g., kindergarten, transition, juvenile, adolescence) that were scientifically verifiable and linked to Darwinistic, and sometimes Social Darwinistic, assumptions about the evolution of humans in the form of races.

In continental Europe, the UK, and the United States, developmentalism was a controversial description of the young that was contested in curriculum debates. In conversations surrounding public schooling and more indirectly in teacher training, the idea that schools and lessons should be built around the child’s developmental stages as opposed to the organization of classical content, such as Latin and Greek, was a radical move that had echoes of Locke’s shift within it (Hall 1901). What had become of the child in such debates was in part explicable by a new theory of and orientation to the child’s powers as in service to racial evolution and nation-building. In Child-study, for instance, only some of the young were considered to have the biophysiological powers to evolve to the next level of development. The body’s internal cellular and genetic powers were given moral and intellectual meaning, generating castes of educability and humanness that lent to racial supremacist discourses a different, but familiar, rationalization for the construction of whiteness in particular as though it was a “deserved privilege.” At the turn of the twentieth century, “the child” bore these wider relationships within its status as a noun, as one who was an exclusive and restricted site and as one who was subjected to welfare reasonings based on a belief in delivering to the young what they were thought “fit for” or “adapted to (Hall,

1904).” The rationalizations that secured both developmentalism and normalized a belief in racially sexed children (i.e., children as those who are raced and sexed prior to sex) have over the course of the twentieth century taken different, yet similar forms, mutating from the anti-recapitulation theories of Piaget which still privileged belief in the staggered development of psychobiological “powers” to the later twentieth-century Vygotskian constructivism that posits a “zone of proximal development” on the way to “becoming” the privileged and participatory adult of liberal democracies to the biologized child of brain-based learning and educational neuroscience whose form and content of Being are pinned to an organological locus (Baker, 2015).

Introduction

There are three distinctive schools of educational thought and research that focus upon the significance of children's relations with animals. Each engages with child-animal relations from a unique disciplinary perspective, in a unique way, and for specific purposes and ends.

The first is a breakaway school within developmental psychology. Researchers in this school insist that child-animal relations are significant to children's development because children grow up in a natural as well as a social environment. They consider the ways in which children's relations with animals enhance their social, cognitive, moral, and emotional development. Taking a critical and more ecologically attuned position within developmental psychology, this research challenges developmentalism's hitherto human-centric, or anthropocentric, focus and seeks to extend the vision of this dominant educational paradigm beyond exclusively human relations.

Within special education, developmental psychologists have a particular interest in child-animal relations. They stress the therapeutic significance of children's interactions with animals and operate from a belief that animals have a calming and a generally enabling effect upon children with disabilities, which can support their development and learning. They therefore promote the practical benefits of applying animal-assisted interventions, activities, therapies, and educational programs for children with a wide range of intellectual and psychosocial disabilities.

The third school of thought and research has emerged more recently. Like the first, it also challenges the anthropocentric premises of human developmental theory, but not from a developmental psychology perspective. It is strongly influenced by posthumanist philosophies and is part of the "animal turn" – an interdisciplinary paradigm-shifting move to decenter the human within the social sciences and humanities. Theoretical and empirical research in this field focuses upon the ethical, political, and environmental significance of children's relations with animals. It engages with child-animal relations as a philosophically and theoretically driven intervention

to decenter the human in education; to reposition the child in a multispecies, not just a human or social world; and to redefine pedagogy.

Child-Animal Relations Within Developmental Theory

Child development scholars with an interest in child-animal relations are still primarily concerned with the development of the child. However, unlike the majority of developmentalists, they insist that it is not only human relationships, and the social context in which these relationships take place, that influence this development. They challenge the anthropocentrism of developmental psychology and point out that in addition to the social context in which children grow up, the broader natural environment and specifically their relations with other species also have a formative influence upon their development.

E.O. Wilson's (1984) biophilia hypothesis has strongly influenced this biological science-based challenge to the anthropocentrism of human developmental theory. The biophilia hypothesis stresses that because of our evolutionary common ancestry, all humans are born with a biological affinity with and innate attraction to other species. Children's instinctive love of animals is often cited as evidence of this. Developmental psychologists with an interest in child-animal relations draw upon the biophilia theory to explain children's natural fascination with animals and to argue that children's development is not only enhanced through their caring relations with animals but also potentially impeded without these relations (Kahn and Kellert 2002).

In addition to the evolutionary biology argument, developmentalists in this breakaway school also point to the fact that contemporary childhoods are saturated with animal presences (Melson 2001; Myers 1998). In other words, children's innate natural affinity for nature and animals is universally recognized and culturally endorsed by the plethora of stories that feature animal characters, as well as by the multitudes of toy animals and other commercial children's

products that are adorned with animal imagery. In addition to this, the majority of children in Western cultural contexts live with family pets, and children in the rural Western and developing world grow up with domesticated farm, village, or herding animals. They argue that it is simply not feasible to deny that animals play a large part in the lives of all children and that the ubiquitous presence of animals is an integral component of all children's growth and development.

Empirical studies of child-animal relations focus upon the developmental benefits that children gain from their relations with animals (Kahn and Kellert 2002; Melson 2001; Myers 1998). These observational case studies look for evidence of the full gamut of developmental markers – cognitive, social, emotional, physical, and moral. Children's natural empathy for animals is often closely observed and evaluated. Case studies of children's free play that observe children involved in animal role-play find that children's capacity to accurately mimic animal's embodied modes of being (the way they move and hold their bodies) is evidence of their cognitive ability to put themselves in the shoes of others (Myers 1998). Other mixed-mode qualitative studies note that children often regard pets as part of their families and have sibling-like relationships with them. Children's emotional development can be witnessed when they respond with love to animals with "cute" faces and display nurturing behaviors toward them (Melson 2001).

Developmental psychologists who specialize in child-animal research are critical of the anthropocentric premises of mainstream child developmental theory. They point to the limits of only ever-casting children's interest in and relationships with animals as immature but useful rehearsals for their optimal functioning in an exclusively human (or social) world. As an alternative to the prevailing anthropocentric premises, they propose a "biocentric" or "ecocentric" approach to human development, which is built upon an acceptance of biophilia and is more in line with the animal-saturated reality of children's lives. Within such an approach, children belong to the natural world, not just to human society, and it is vital that they develop a sense of full

environmental stewardship – a responsibility to care for all forms of life, not just a sense of social responsibility (Melson 2001; Myers 1998). From this ecological child development perspective, child-animal relations are seen as significant *in their own right*, not merely as a preparatory stage for enhancing their all-important social development and human relationships.

Child-Animal Relations Within Special Education

Many developmental psychologists working in the subdisciplinary field of special education advocate for the use of animal-assisted activities, interventions, and learning-support programs for children with disabilities. The opportunity to interact with animals is seen as beneficial for children with a wide array of disabilities, including cognitive impairment, developmental delays, and psychosocial and behavioral disorders (McCardle et al. 2011).

There are a number of different kinds of animal-assisted activities, interventions, and programs within special education. These range from the daily presence of individual children's service dogs to the keeping of small pets and animals in classrooms and playgrounds, to regular visits to horse-riding schools for the disabled, and to longstanding and full-scale residential animal-assisted therapeutic and education programs in special schools such as Green Chimneys, in New York State in the USA (Ross 2011).

Those advocating for animal-assisted activities in special education share an unpinning faith in the power of the human-animal bond and a belief that children's relationship with animals is not only therapeutic but also has the potential to enhance their learning outcomes (Ross 2011). Although the integration of animals within special education programs, in one way or another, is almost a standard practice today, there have been scant empirical studies of the effects of animals upon children's learning. The emphasis remains upon the application of the best practice and upon anecdotal rather than evidence-based evaluation. Some common observations are that animals have

a calming effect upon children. They help them to relax and to feel safe, to stay focused, and to hold attention. They offer companionship without judgment, thus providing comfort for anxious children. The general consensus is that the presence of animals creates an emotionally stable environment that helps children to gain confidence and build skills (Ross 2011).

Child-Animal Relations Within the “Animal Turn”

This third school of thought is aligned with the “animal turn” – a newly emerging interdisciplinary intellectual paradigm that is premised upon an understanding that the way we think about ourselves as humans is closely connected with the way we think about other animals. It challenges the anthropocentrism of humanist philosophical traditions, including the foundational belief that humans are separate from and superior to other animals because of our exceptional capacity to reason and to exercise intentional agency. In short, the “animal turn” is an intervention associated with posthumanist philosophy, which refutes the Western divide between humans and animals and calls for new ways of thinking about human-animal relations, about subjectivity and about agency.

Many of the scholars who engage with the “animal turn” and study child-animal relations are from the subdisciplinary fields of environmental education or early childhood education, or they straddle both. They engage in interdisciplinary scholarship that is informed by environmental philosophy, science and technology studies, human geography, environmental sociology, and the environmental and indigenous humanities. They call for a regard for other species as subjects in their own right; for the recognition of the complex entanglement of human-animal relations; for an attendance to the ways that children’s past, present, and future lives are bound up with those of other species; for a repositioning of children’s lives within multispecies common worlds; and for the application of ethical, political, and environmental frameworks to child-animal common

world relations (Oakley et al. 2010; Common World Childhoods Research Collective 2015).

The philosophical shift associated with the “animal turn” has a number of implications for education. In particular, it prompts a reconceptualization of the relationship between the subjects and objects of knowledge that underpin pedagogy and research. It offers a direct challenge to the mantra of child-centered learning that prevails in early childhood and primary pedagogies. It also challenges the standard pedagogical practice of learning about the natural world (including animals) as an object of study within environmental education (Taylor and Pacini-Ketchabaw 2015; Oakley et al. 2010). Educational proponents of the “animal turn” are beginning to explore the pedagogical implications of *not* separating ourselves off from other species, of shifting the pedagogical focus from the child to the child’s relations with other species, and of considering what it might mean to learn *with* other species, not just about them (Rautio 2013; Oakley et al. 2010; Taylor and Pacini-Ketchabaw 2015).

Research that engages with the “animal turn” requires new methodological approaches that resist the interconnected human/animal and subject/object divides, decenter the human, and regard animals as agentic subjects rather than passive objects and as active partners in child-animal relationships. Multispecies ethnographies, affect-attuned observations of child-animal encounters, and narratives that trace the semiotic and material entanglements of children and animal’s lives are examples of the kinds of experimental methodologies that are being used to approach child-animal research in relational rather than dualistic ways (Rautio 2013; Taylor and Pacini-Ketchabaw 2015).

Many of these studies of child-animal relations are framed by broader ethical, political, and environmental considerations. These include the ethical and political implications of future generations (of human and other-than-human animals) inheriting an anthropogenically damaged planetary environment and the issue of how to foster multispecies belongings and convivial multispecies cohabitations in a time of mass species

extinctions (Common World Childhoods Research Collective 2015; Taylor and Pacini-Ketchabaw 2015).

Conclusion

Approaches to the study of child-animal relations vary considerably. While all three schools of thought and research discussed here promote the intrinsic value of interspecies relations and, more specifically, the pedagogical significance of children's relations with animals, they have different disciplinary perspectives, draw upon different theoretical frameworks, use different methodologies, and are differently motivated.

The developmental psychologists who study child-animal relations from within a developmentalist framework seek to replace their discipline's dominant anthropocentric focus with a biocentric approach to child development. Within this biocentric approach, children are seen as having an innate (biologically determined) connection to animals. Their motivation is to convince their colleagues that children's development and learning can only be enhanced by taking the child-animal connection seriously.

The developmental psychologists who promote animal-assisted pedagogies within special education share this belief that children have a special connection with animals. However, they are less concerned about challenging the anthropocentrism of dominant child development paradigms as they are with the business of integrating animals into special education programs in order to assist children with disabilities to thrive and learn.

The last group, more commonly affiliated with environmental and early years education, approaches child-animal relations from outside a developmental psychology framework. They are interdisciplinary scholars, who have been influenced by the more than human or "animal turn" that has spread across the social sciences and humanities over the last decade. Along with the first school of scholars, they share a desire to

challenge the anthropocentrism of the dominant child development paradigm. However, unlike them, they do this by engaging with posthumanist theory and philosophy and calling for a complete paradigm shift in the way in which we think about what it means to be human and our relations with other species. Their work is heavily theorized but also empirical, as they study the ways in which child-animal relations might shed light on the big-picture ethical and political questions of interspecies cohabitations in ecologically challenging times.

Consumer Culture and Children

Rapid shifts and trends in the economy and technology are reshaping the experience of childhood for young children throughout the world. Developmental psychologists, early childhood educators, and many parents espouse that childhood is under siege by powerful global forces with the influence to corrupt innocent and vulnerable children, destroy local cultures, and homogenize the planet. On the other hand, marketers represent the child subject as a savvy consumer with a right to resources. These competing discourses collide

dramatically in the discussion/debate surrounding corporate marketing to children. Businesses posit their marketing to children as an act of empowerment by equating freedom with the power to consume. This entry examines current discourses surrounding marketing to children within the context of a globalized consumer culture.

Globalization and Consumer Culture

Globalization is a term that is frequently used in education and policy reform. The term globalization itself is used to describe the processes that open up local societies to influences beyond their regional or national borders. These influences are economic, cultural, political, and societal and affect the everyday contexts for all of us, including young children. Educators are feeling increased pressure to adapt curriculum and rethink pedagogy to meet the needs of “today’s globalized child.” But who is this globalized child? It is important to recognize that childhood is a historical, cultural, and contextual construction.

This is not to discount the obvious changes that have occurred in recent years. Throughout history childhood was the site of social and cultural reproduction. Today, children in industrialized nations spend more time with globally produced media than they do in school, asleep or with their friends and family. Even in rural parts of the Global South, access to mobile phones and other electronic media is making international consumer culture a mainstay in the lives of children. The image of a child at play in the neighborhood park with friends may be alive and well, but it is more likely that this child is in her room with headphones watching television and simultaneously gaming on a mobile phone (Buckingham 2007). This reality is giving marketers unprecedented access to children.

These “new times have ushered in a new era of childhood” (Steinberg and Kincheloe 2004, p. 1). Currently, media use begins in infancy, with, on any given day, 29% of babies under the age of 1 watching an average of 90 min of television per day. That number jumps to 64% of children 12–24

months of age (Rideout 2011). Preschool children spend between 4.1 and 4.6 h per day using screen media. By the time children are 8 years old, they are spending more time with screen media than they do in the classroom. It stands to reason that if children are spending more time with media than in school, consumer culture has become the central curriculum of childhood (McNeal 1992).

Historically, children have been targeted as a segment of the consumer market, but today children are being groomed from birth to become super-consumers (Bakan 2011). There are several factors that have led to an increase in the levels of corporate marketing to children. The deregulation of the advertising industry in the 1980s opened up the floodgates to advertisers, putting fewer restrictions on advertising to children and creating an explosion in cable television that expanded youth programming and promoted corporate “kid culture” (McNeal 1999). This, combined with the explosion of new technologies (the Internet, home video game consoles, portable music players, DVDs, home computers, portable handheld video game systems, MP3 players, DVRs, electronic interactive toys, Internet-connected smartphones, and tablet computers) of the current era, has completely changed advertising.

From birth, children are being targeted as future customers. In his 1992 book, *Kids as Customers*, McNeal advises companies that they only have two options when it comes to creating new customers: (1) convince someone to switch to their brand from a competitor or (2) get a customer who is newly entering the market. Children fall into the second category and, as such, are highly valued and sought out by companies wanting to gain their brand loyalty as early as possible. Current estimates show that marketers will spend approximately \$15–17 billion per year to advertise to children in the United States. This is a huge increase when one considers that in 1983, advertisers were spending a mere \$100 million. This dramatic increase in advertising spending has been fueled by new technologies such as the Internet, social networking, video games, and personal smartphones. Research has estimated that children view approximately 40,000 advertisements per year (Kunkel et al. 2004).

Several studies have examined the link between children’s media use and the effects that increased exposure to consumer culture had on their well-being. Children are grown, groomed, targeted, manipulated, and made to feel insecure and anxious from birth to be more susceptible to advertising. A UNICEF report (2007) found that children in the United Kingdom scored low on a scale of quality of life in comparison to the other countries being rated. The report identified the United Kingdom’s materialistic culture, combined with its high levels of social inequality as a key reason for the lower score for children’s well-being. The survey, which was conducted with children across several European countries, concluded that:

Consumerism appears to have become inextricably enmeshed in children’s relationships with family and friends . . . families in the UK, more so than in Sweden and Spain, use the purchase of new material objects (particularly new technology) in an attempt to compensate for relationship problems and social insecurity. In the United Kingdom parents and children seemed to be locked into a compulsive consumption cycle. (2007, p. iii)

The report centered on a tug-of-war that children described as the desire for quality time with their parents and their own intense feelings of desire for electronics, brand-name clothes, and other expensive items. Children explained that they did not have as much time to spend with their parents who felt compelled to work long hours. In contrast children in Spain and Sweden felt much less pressure to purchase consumer items. The UNICEF report highlighted the differences in culture and governmental priorities between the countries. A shift in national priorities was suggested for the United Kingdom, one that moves away from a focus on consumerism at the expense of children and families.

Governmental Regulation of Advertising to Children

This UNICEF report, along with an increase in childhood obesity, revitalized the debate about who should police or regulate advertising to children. Individual countries have taken various

approaches to the regulating of broadcast advertisements aimed at children. In the United States, the Federal Trade Commission (FTC) creates the guidelines and polices the advertising industry. However, pro-business lobbies have effectively convinced congress to strip away at the authority of the FTC. The FTC has all but abdicated its role as regulator and left the advertising industry to self-regulate, claiming that it is the least intrusive and most responsible way to regulate (Linn 2005).

Government regulation of advertising to children is regulated in many other nations throughout the world. For example, in 1991, Sweden banned all advertising aimed at children, and they did so with the majority of their population's consensus. The Swedish government has explained their rationale for the popularity of these regulations as based on the belief that children under the age of 12 are not able to fully understand a commercial's intent and are not fully capable of being educated consumers. In 2000, Sweden's leader took the helm of the European Union and attempted to convince fellow members to follow their lead and enact a total ban on direct advertising to children. The total ban may have passed had it not been for the intense objection of the United Kingdom. The United Kingdom's answer to the political pressure was to initiate a media literacy program in its schools to better educate children as consumers. The program, named Media Smart, was a compromise argued for by advertisers. Rather than enact a total ban on advertising aimed at children, in 2009, the European Union passed the EU Audiovisual Media Services Directive. This directive lays out regulations on advertising to children that apply to all 28 European Union members. The EU Audiovisual Media Services Directive is broad and has been adopted and enacted within the various countries in a multitude of ways. For example, Greece has a ban on children's toy advertisements during a typical child's waking hours (from 7 AM until 10 PM). They also have a complete ban on the advertising of toys that encourage or glorify war. In Sweden and Norway advertising to children under the age of 12 is completely banned. In Denmark and Belgium there are also government restrictions on advertising to children.

Constructions of Childhood Within the Debate Over Advertising to Children

Two dichotomous paradigms of childhood can be identified throughout the literature and tend to be pitted against each other within the debate about children and advertising. They are *the vulnerable child* and *the empowered child* paradigm. Although these paradigms are overlapping and related in some ways, naming and dividing them in two categories can help to define the views about childhood from which the research stems.

The Vulnerable Child Model

The assumptions that make up *the vulnerable child paradigm* are rooted in developmental psychology and are reflected within the research and advocacy surrounding marketing to children. The research on advertising to children falls into two main categories, a child's ability to watch, recognize, understand, and remember advertisement and a child's reaction to the messages within advertisements.

The first body of research found that (1) young children are unable to recognize advertisements, (2) they have difficulty differentiating between commercials and programming, (3) they do not understand the intent of advertising, and (4) advertisements are misleading. The second body of knowledge that was presented examined the messages within advertising and how children reacted to these messages. These findings are as follows: (1) the advertising of unhealthy products such as alcohol, tobacco, and junk food have contributed to a rise in youth tobacco and alcohol use and the childhood obesity epidemic; (2) the marketing of violent movies, games, and toys have led to a general desensitization of violence and the use of gender stereotyping to sell violent toys to boys; (3) marketers are using the developmental concept of gender differentiation to sell girls highly gendered and sexualized toys, clothing, and media products; and (4) there is mounting evidence that advertising to children can instill materialistic values that may harm children's physical and psychosocial well-being.

Throughout the world, coalitions of parents have joined with health and education experts to fight against what they see as the predatory

practices of advertisers. These groups argue that the commercialization of childhood is having devastating effects on children's physical, mental, emotional, and spiritual well-being. They focus on advertising's unintended, harmful effects. Interestingly these coalitions represent a broad cross section of the political spectrum. Organization such as Commercial Alert are concerned mainly with the corporate influence welded over children and are more in line with other corporate protectionist groups. On the opposite side of the political spectrum, the Motherhood Project is neo-conservative politically, but they have joined forces with this coalition because they are concerned with the messages of sexualization and glamorization of the celebrity culture that goes against wholesome "family values."

Sociologists and anthropologists have criticized the vulnerable child model for several reasons, firstly for being biologically essentialist. It fails to take into account children's individual personalities and characteristics. This model paints children as almost "zombie-like" creatures that are unable to withstand the influence of advertisers who are able to control their tastes, desires, and behaviors. They critique this model for being too simplistic. Children are seen as subjects without agency and therefore must be protected by adults.

Sociologists have pointed out that the coalition fighting the commercialization of children is simply taking part in the time-honored tradition of the older generation worrying about the younger one being corrupted by a new technology. This is often referred to as a "moral panic." They point out that comic books and radio were also protested as a corrupting influence. Furthermore, the adults who cast their gaze on the child and their explanations are often an attempt to make sense of "childhood" while at the same time dealing with their own anxieties, frustrations, and fears about the future. A final critique of the vulnerable child model is that it is elitist. Critics point out that the majority of the members of the coalition to ban advertising are educated, white middle- to upper-class parents. Some have critiqued them as classists who worry that the consumer culture is vulgar and that adult world is full of greed, violence, and sex. In

contrast, children are inherently pure, innocent, and full of wonder.

The Empowered Child Model

The empowered child model views children as active agents who are capable of contributing to their construction of their own subjectivity (Steinberg and Kincheloe 2004). Critical early childhood theorists, sociologists, advocates for media literacy and marketers tend to fall into this camp for different reasons.

Critical theorists and sociologists point to a blurring of the lines between childhood and adulthood. They posit that today's children are exposed to adult issues much earlier than those in past generations. They challenge the "positivist conception of children as voiceless passive entities that need to be controlled and regulated by adults" (Share 2009, p. 101). Instead of banning advertising to children, they promote media literacy awareness as a way to combat some of the negative effects of advertising. Media literacy curricula teach children about the television and advertising industries, discuss the intent of advertisements, and aim to provide children with the skills they need to think more critically about media. It is a field of study to itself, and as such, there is a large body of evidence that shows media literacy can be an effective intervention for teaching children to think critically about advertisements.

Curiously these are the very same arguments that are being made by marketers who want to be able to market to children. Marketers have successfully touted purchase power as synonymous with purchase power. The advertising industry has been very influential in the construction of the empowered child model. Children are seen as savvy consumers who are able to make purchasing decisions beyond influencing their parent's decisions. Children as consumers are able to shift markets and shape kid culture. Children are seen as powerful markets whose tastes and loyalties are researched and catered to by multinational companies.

The empowered child model is critiqued for believing that consumers always act in their own best interest, based on making rational decisions. This does not take into account that marketing can

and often does mislead individuals and influence their tastes and/or their self-concept. If this were not the case, corporations would not be spending billions of dollars annually on trying to influence children.

Advocates for a third way point out that it is not only children who need sole protection from the evils of corporate culture but rather everyone is playing David to their Goliath (Schor 2004). This third perspective asserts that a hyper-consumerist culture is not good for anyone. The aim within this perspective is to break down the child-adult dichotomy and examine the negative effects of advertising as a culture. Certainly, adults suffer from obesity, tobacco addiction, alcoholism, poor body image, excessive debt, and impulsive spending. By separating children from adults, the discourse centers around what is appropriate for children at what age and how children should spend their time (i.e., screen time vs. outdoor time). The discourse is about controlling and protecting the innocent child until that child is developmentally ready to enter the “adult world.”

Schor (2004) called for an *Integrated Child and Adult Critical Perspective*. Within this perspective, it is argued that aspects of consumer culture impact everyone negatively, not only children. Rather than aiming to solely protect children from the many toxic bi-products of corporate influence, people should be fighting to make the world safer and healthy for everyone.

In Conclusion

This article has presented a glimpse into the context and discourses that surround and attempt to define childhood within a global consumer culture. Children are growing up within an increasingly commercialized culture, one that supports the view of children as “profit centers.” More research is needed that moves beyond the dichotomous paradigms that currently dominate the discourses about children and consumerism. It is also important for educators to include counter-narratives that challenge the dominant messages in consumer culture. These messages would promote environmental responsibility and the value of people and experiences over material things.

Childhood and Otherness

Sonja Arndt

Childhood and difference; Childhood and diversity; Childhood and foreignness

Introduction

We wonder whether an increased focus on the ethics of difference in childhood and different manifestations, both discursive and material, . . . can help to expose the generative in childhood otherness, and sustain the generative in infinitely unnamed, unknown, scary, and unrecognizable childhood 'subjects and objects'. (Tesar and Koro-Ljungberg 2015, p. 4)

This entry theorizes perspectives on Otherness as they relate to childhoods. Grounded in seminal and contemporary theories on constructions of childhoods, it focuses specifically on conceptions of foreignness, the stranger, or the Other in relation to children and childhoods. The entry intersects a philosophical engagement with the Other with particular impacts and possibilities that arise for children as or with the Other. It raises issues associated with childhoods entangled with and generative of different manifestations of Otherness, as alluded to by Tesar and Koro-Ljungberg in the opening quote. Given the complexity of possible impacts and implications of Otherness on children and childhoods, this entry offers a consideration of possibilities, in this multifaceted, ever-more-political complication of childhood/s.

While the focus of this entry is on aspects most related to cultural Otherness, the considerations can apply in similarly complicated ways to wider notions and experiences of Otherness for children. Connections may be apparent, for example, with Otherness arising from normalizations of gender and conceptions of disability or of school achievement, behavior, or beauty and further

marginalizing phenomena that affect children and their understandings of themselves. Given the multilayered and diverse possible impacts and implications of Otherness on children and childhoods, this entry argues for an ethical approach to Otherness and to exploring and elevating, rather than knowing, or worse eliminating, Otherness. Its aim is thus to problematize rather than clarify complexities, to provoke considerations of responsible, ethical, and just engagements.

So, this entry offers no particular truth or conclusion, but rather, it suggests that there can be neither. Julia Kristeva's theory of subject formation supports a view of subjectivity as an ongoing and unknowable construction and offers a philosophical and psychoanalytical lens for this examination. The entry draws on Kristeva's (1991) theorization of the notion and experiences of the foreigner and foreignness and of the ongoing nature of subject formation, suggesting possible alternatives, conceptions and insights. It uses the example of contemporary refugee and migrant crises as a prism on childhood-Otherness realities. By emphasizing Otherness as an ethical challenge, the entry aims to provoke questioning and critically rethinking refugee and migrant children's experiences and realities of Otherness.

In the sociology of childhood, childhoods are seen as socially constructed. Childhoods thus arise as products of their time, culture, and relationships, and children are considered members of their society and as actors within it (James et al. 1998). What then does Otherness mean for these childhoods in transit? As socially constructed childhoods, how does it manifest in the everyday lives of children? Any attempt to define the notion of Otherness belies its very essence, since the revelation of such an exposure renders it familiar and no longer Other. This entry follows Tesar and Koro-Ljungberg's (2015) conception of Otherness as "difference," "both discursive and material." Otherness, then, may manifest in various degrees of difference: as merely a little bit strange, stranger, or too strange. Kristeva's (1991) narrations in her book *Strangers to Ourselves* anticipate possible impacts of Otherness through confrontations with the foreigner.

A foreigner, she states, for example, can cause “a choked up rage deep down in my throat,” and can be seen as “a black angel clouding transparency” (p. 1). Following this view, foreigners, strangers, and Others that are discursively or materially different might be seen as an unwanted disturbance, causing a state of anxiety, interrupting children’s everyday normality and routine. Otherness then is concerned with an unfamiliar, unpredictable difference, while the “choked up rage” indicates that such a difference might also be upsetting, worrying, and angering.

Conceptions of Otherness have evoked ethical commitments to tolerance in the past, for all of humanity to live together, on this earth, for example, despite, with, and across political, cultural, religious, and linguistic differences. Some philosophers such as Camus emphasize, similarly to Kristeva, that this is not so simple and that difference can cause resentment, even fear, as the Other may behave, feel, and think differently to the dominant expectations in society and in ways with which others do not agree (Camus 1946/1988). Others, yet, follow the material Otherness referred to above, to claim that Otherness exists not only in the human but in the post-human realm of new materialisms and decentralized child-nature binaries and matter, beyond romanticized and normalized visions and constructions (Malone 2016). Kristeva’s (1991) “black angel” then could metaphorically represent the Other from some of these intricately entangled perspectives, as the subject, object, thing, or matter that behaves (lives, eats, dresses, believes, plays, exists, moves, or infuses) differently, “clouding” known, expected, normal routines, rituals, beliefs, and values of the everyday mundane life of childhood. Situating normality and Otherness is more than a simple dichotomous relationship between one and the other, and engagements with the ethics of Otherness, bearing in mind all of the above aspects, are deeply intertwined and entangled.

The layers of complexity of ethical engagements with Otherness can be seen through Kristeva’s notion of foreignness. For Kristeva (1991), foreignness is fluid. It involves an Otherness that arises from a removal from one’s origins,

either from a situated or metaphorical home- (or mother-)land. She likens to a “demented whirl” (p. 6) such strangeness that can trigger dramatic highs and lows, blurring boundaries, to the point where there is no longer just one or the other, but a constant state of both, of flux between familiarity and the Other. She describes foreigners as hiding behind diverse masks, rootless, wandering, attempting to fit in, with new communities, hiding their disappointments and sadness. Following Kristeva, affirming the foreigners’ identity becomes a tenuous affair: Where do they belong? Everywhere? Nowhere? And what counts, in the new place, citizenship, passports, or geographic locality – acceptance in society, the social grouping, work, or community? Situated thus, the foreigners’ Otherness can be determined in many ways: legal, physical, contractual, emotional, and spiritual. It can be perceived as a potentially creative situation, offering new challenges and opportunities, or raise angst and guilt, the “choked up rage,” toward the future or the past that is left behind.

Similarly to Kristeva’s foreigners, children confronted with Otherness can experience it in multilayered and complicated ways. Their experiences may or may not be visible, clear, or understood by adults, as they too apply various masks, become uprooted, and seek new ways of fitting in. War and poverty are major reasons for families to flee their homelands in the contemporary global political and social climate. Childhoods in refugee situations are childhoods embroiled in Otherness. They turn the questions facing the foreigner to questions of children’s being and belonging, as members of a community, of a school or early childhood setting, belonging to a church, maybe, or to a football club, and critically, as citizens, belonging to a nation State. Current refugee crises, in Europe, for instance, have created situations for children, where very much of life that was once familiar is now not. The Otherness of life drives them and their families to risk and humiliation in major traverses across water and land that represent more of the unknown than can be imagined. With their homely, community and social landscapes often literally obliterated, these children’s childhoods themselves have become

childhoods of Otherness: unknown and unknowable, like, for Kristeva, the foreigner himself.

Understanding identity is complex, and in trying to do so, Kristeva (2000, 2008) has repeatedly raised the question of European identity and culture. Does it exist? And if it does, what is it – and what is its Other? Her response reflects her philosophy on the subject, as forever in process, as she claims that “there does exist an identity, mine, yours, but it is infinitely in construction, de-constructible, open and evolving” (Kristeva 2008, p. 2). The daily news reports of refugees escaping war and other atrocities explicate some of this evolution that Kristeva sees as “infinitely in construction” and “open and evolving.” Territorial and personal fragilities play out in many ways, along railway lines, in the cold and rain, maybe being with loved ones, and for many others now separated, and in knowing that the fence along which they walk has been erected as a specific act to ostracize and exclude.

The disruption and Othering in refugee children’s lives, then, occur on multiple levels and in multiple, intertwined ways. One element of their previous normality that becomes disturbed is their education – at least in the sense that was known, familiar, and planned for them and for their future place in their society. The experiences of exile, escape, care, and dependence with their extended families and other refugees, as they traverse foreign landscapes, through refugee corridors that have been constructed specifically for the purpose of containing the tide of people (explicitly Othering them in the process), are arguably deeply educational in many ways. Furthermore, temporary educational facilities operate on a small scale along the way. Such an example can be found in Kilis, on the Syrian/Turkish border, where Ahmed has opened a space (and his heart) for children, offering them a temporary educational setting and a hint of “normality,” as he tutors children through school- and kindergarten-like experiences. He helps them to come together, child-Others, with others on the march, to try to make some sense of their lives in their temporary alienation and Otherness. He also helps them with regaining a sense of trust in humanity, as

he smiles, teases, and seems to understand (Smalley 2015), for the moment.

Refugee crises arouse moral and ethical positionings. Strong calls for increased protection of children in refugee situations deepen concerns with/for the child Other. Removed from no-longer-safe homelands, refugee children’s childhoods can be seen as endangered, in terms of deviating from their previous normalities: their childhoods are no longer what they were and the social construct no longer fits. What does childhood mean, for child refugees? Through a Kristevan (1991) lens that sees identities as always in constant construction, the realities of these childhoods perhaps prematurely impose on children the concept that one is always also a foreigner within. Otherness in this sense may create for refugee children a disappearance of their childhood, in the blurring of lines between what are considered to be childhood concerns and those that only adults should have to deal with. When their childhood is relegated to exile in detention centers, for example, or on the march and sleeping under bridges, or in a boat, awaiting political decisions on their status, rights, and further thoroughfare to safety, refugee childhoods are prematurely thrust into adult-level Othernesses and danger. How such Otherness endangers childhoods depends on the situation, histories, culture, and citizenship of the refugees and the dominant orientations toward childhood in each situation. In addition, conceptions of ethics and of danger and Otherness are further complicated by the idea that escaping home, and risking exhaustion, humiliation, debt, and death in unknown lands, is considered a safer alternative to remaining in war-torn homelands.

Otherness in relation to children implicates rights conferred by internationally mandated declarations, such as the United Nations Convention on the Rights of the Child (UNICEF n.d.). Exorbitant numbers of child refugees currently fleeing their war- and poverty-torn homelands escalate concerns related to basic humanitarian rights to eat, sleep, and wash, and already pressing issues with holding religious beliefs, practising cultural rituals and routines, having and

expressing a voice to nondiscrimination. While Ahmed might offer temporary refuge and create a minimal educational context for children Othered as refugees, long-term implications are barely imaginable, in this political, cultural, and social volatility. Where will these children be allowed to settle? What will the local constructs of childhood be in that social, natural geographic place and space, and how will children who have experiences of such turmoil be able to live there, as Kristeva (1991) further suggests, “without ostracism but also without levelling” (p. 2)? The ethical responses to childhoods and Otherness called for above, for tolerance, and for recognition of the complexities, fear, and unknown subject-object-matter and child-nature relationships thus play out in localized as well as global, social, political, and historical realities, further entangling and mirroring the in-betweenness of their situation.

A further implication of childhood Otherness in refugee situations, as hinted above, is the concern with the foreignness within. While Kristeva is clear that identities are in constant construction, childhood confrontations with Otherness evoke her assertion that the “foreigner lives within us,” that “by recognizing him within ourselves, we are spared detesting him in himself,” and, furthermore, that the foreigner only “disappears when we all acknowledge ourselves as foreigners” (Kristeva 1991, p. 1). Conceptualizing the foreigner within, in each child, adult, and perhaps even beyond, turns the conceptual lens onto the individual, child, adult, citizen, and alien. . . and thing, matter, and nature. It further affirms the ethics of Otherness, by eliminating the need to know and creating instead a state where the unknown offers an openness that allows for ambiguity, uncertainty, and generative possibilities. Kristeva’s interests in the European subject and identity provoke dialogue and possibilities for urgently rethinking Otherness and possible ways forward for child Others.

A European destiny, identity, residency, and security, is the dream that drives families with young children in the current waves of refugees from Syria. While the European Union might be seen as a “global civilizing effort” (Kristeva 2000,

p. 114), where differences must be coordinated and reconciled, this, Kristeva claims, requires a renewed establishment of subjective freedom, toward a meaningful and useful Europe. Refugee childhood experiences involve such a complicated and entangled daily evolution that embeds their forming subjectivities strongly within Othernesses caused by globalization, political identities and ideologies, freedoms, far beyond their immediate situation. The very critical concern is for a Europe that is even liveable. Through conceptualizing child refugee questions of knowing the self, the unconscious and the Otherness within, in relation to the other Othernesses, push to an extreme what Kristeva (2000) calls a crisis of the European subject.

Childhood and Otherness are enacted through refugee children fleeing across Europe. Finding temporary refuge with people like Ahmed, they briefly elude the brazen acts of extreme Othering on their journey: stun grenades, pepper spray, and teargas that impact in unknowable ways on the Otherness within themselves. For refugee children, even if they make it into a new country within Europe, they may, as Kristeva (2000) goes on to say, feel liberated; however, they will most likely remain Other. Their ontological realities, perpetuated as for Kristeva’s (1991) foreigners, through “incoherences and abysses . . . the strangenesses” (p. 2), continue to be governed by also evolving, unknown public and private political, social, and environmental spaces and places. Children’s Othernesses thus both play out and reflect many “demented whirls” of highs and lows, blurring and uncertain boundaries, of their own identities, those of the subjects, objects, matter, and energies of their surroundings. Kristeva’s ideas offer a particular framework for examining conceptions and constructions of childhoods confronted with and engulfed in Otherness. Refugee childhoods have been selected for this entry to foreground an urgent concern for their shifting and complex identities, freedom, and rights and to elevate refugee children ongoingly in the global awareness and in the daily march of their deepening, complex histories, localities, realities, and Otherness.

social experience” (Fass 2004, p. xi). Historically, childhood “reveals important assumptions and constraints in the larger social environment” (Stearns 2006, p. 3). Certainly this field is most pertinent to educational scholarship, and its teaching often sits squarely within education studies. Schooling and education framed more broadly both figure prominently in recent historical writing about childhood and youth. Yet the field is not restricted by this; historians of childhood and youth are to be found teaching and writing about it across many academic contexts, drawing on a rich diversity of historical and interdisciplinary perspectives. Furthermore, they do so from a wide range of global contexts, utilizing comparative studies to paint a picture that is both fine grained and richly hued; and internationally they are supported by a growing and impressive infrastructure of academic societies, conferences, journals, books, encyclopedias, and specialist readers. This article introduces the field in broad terms by outlining its development, assessing its wider significance, and considering some of the opportunities and challenges still to be faced.

Development

It is commonplace in Western scholarship to trace the historiography of childhood and youth back to the seminal work of the French *Annales*-aligned historian Phillippe Ariès (1962). Historians have used his thesis that childhood is a relatively modern concept dating from around the seventeenth century as a starting point for further research and disputation. This, however, was something of a “false start.” It did set the stage for understanding childhood in historical terms, and it has engendered keen debate in such a way as to clearly put the history of childhood on the map. However, it became overly simplified or was misrepresented by those who followed (who focused somewhat unhelpfully on contrasting “premodern” and “modern” conceptions of childhood or who erroneously tackled the idea that premodern parents held no affection for their children), and it effectively set the field within Western terms or parameters.

Childhood and Youth, History of

Hugh Morrison
College of Education, University of Otago,
Dunedin, New Zealand

Introduction

The history of childhood and youth is a lively scholarly focus, reflecting several decades of innovative pedagogy and research. It is now an “energetic field of inquiry that provides critical insights into the human past and contemporary

Ariès certainly kick-started genuine and concerted historical interest, yet the significance of his work is more broadly situated. The emergence of a focus on children and youth necessarily reflected wider changes in society and in prevailing historical discourses. In this respect Heidi Morrison provides a helpful framework for understanding how the field began and developed. She argues that there have been at least four paradigm shifts since 1960 (Morrison 2012, pp. 1–5). These shifts are not chronologically contiguous as they overlap to some extent even in the present day. Phillippe Ariès' work represents the first change, what she terms "childhood discovered"; childhood and youth were identified as an inherently important historical focus and category. Newly emerging histories of children and young people in the 1960s and 1970s were part of a larger "subaltern" approach to history, otherwise referred to as "history from below," wherein historians generally "began to probe the past for insights into lived experiences" (Fass 2004, p. xi) and worked to reclaim the histories of so-called powerless social groups (including children) hitherto missing from historical narratives. This coincided with a period of intense social and political ferment, vociferous "liberation" movements, the development of feminist thinking, and a new academic focus on hegemonic structures or institutions of control and discipline, prompted in particular by the work of Michel Foucault.

By the 1990s, reflecting the influence of cultural history and of poststructuralism, a second shift emphasized the ways in which childhood could be reconceived as a "social construct" susceptible to different interpretations, rather than as a category fixed across time, space, or cultures. Focusing on children's experiences as much as on the institutions shaping their lives, historians became interested in how such factors as culture, gender, race, class, nation, environment, and religion served to variously define different childhoods. This approach is still pervasive and has accentuated children's experiences as much as the ideas about them. At the same time, however, it has served to reinforce a problematic binary of "children" and "childhood," which some scholars argue is a distinction that has unhelpfully

"haunted" the field and which is not easily resolved (Olsen 2015, p. 13).

A third, and understandably contemporaneous, paradigm shift highlights the nature of "global childhoods." On the one hand, this means that histories of childhood in non-Western contexts are increasingly appearing, albeit at a slower rate than the production of histories of Western children and young people. There is, for example, a lively field of interest around Latin American children and childhoods; and it is customary in edited collections now to read histories across the spectrum of African, Asian, Pacific, American, and European cultural or geographical contexts and to interpret children's and young people's lives in non-Western terms. On the other hand, attention has turned to a "world" or "global" history approach to children's lives, seeking to compare the commonalities and differences in conceptions of childhood, children's experiences, and the ways in which their lives are variously shaped by the forces of globalization and modernity. Yet there is a further element to this not quite captured here. A newly emergent thread in research and writing – influenced by a mixture of postcolonial, cultural, new imperial, and religious history – is shedding light on the ways in which both colonial and colonized children have variously lived within or been influenced by imperial and transnational networks or influences. Comparative studies thus highlight the reality that "spontaneous, parallel emergences and new departures within the meaning of childhood in different parts of the world reflect a modernity only partially controlled by metropolitan authority, engaged with organically by children and filtered through or checked against local knowledge, local customs and local ways of thinking" (Olsen 2015, p. 15).

A final shift, one that is very much still in progress, is a move toward the practice of children's history becoming more "multidisciplinary" (drawing on different disciplinary perspectives to inform historical understanding) and "multi-generational" (wherein children become research participants and apply a self-reflexive hermeneutic). The first is necessary and logical, given the complex nature and settings of children's lives.

The second is perhaps more aspirational, although the predominance of oral history, as a methodology, to some extent helps to bridge the gap between researcher and subject or past and present. All of these changes in emphasis are significant and have had a demonstrable impact on scholarship. This is broadly and amply evidenced, for example, through the publication over the last decade or so of four important reference collections: the three-volume *Encyclopedia of Children and Childhood in History and Society*, the six-volume *Cultural History of Childhood and Family*, Peter Stearns' *Childhood in World History*, and *The Global History of Childhood Reader* (see References) (Foyster and Marten, 2010).

Significance

Histories of childhood and youth matter because children and young people matter. While it might be argued that this is a politically or culturally situated observation, nevertheless it is true if the histories of other people (ages, genders, races, religions, classes, etc.) also matter. Therefore, if the history of children and young people focused on nothing more than the reclamation of their spaces and stories within the historical record, then that in itself would be sufficient justification. Some reclamation history clearly amounts to little more than disconnected or inchoate accounts or indeed is another form of antiquarianism, but that is not the whole story. The sum total of childhood and youth history conducted over the last four decades has added significantly to our understanding of the who, where, when, what, and why of children's lives and experiences. There now exists, for example, a greater body of knowledge about children's lives over the *longue durée* of human history stretching from ancient origins, across a range of civilizations and cultures, and through a great many historical eras straddling so-called premodern and modern times. At the same time, historians now have a much more nuanced or differentiated understanding of what influenced conceptions and experiences of childhood in the past and how those have changed, at a

range of scales from the local to the global, and increasingly differentiated by race, gender, class, religion, and nation.

At the same time, the question "why pursue the history of children and young people?" is worth considering on a range of other levels. The "history of childhood," argues Steven Mintz, "is anything but a trivial topic. Childhood . . . is the true missing link: connecting the personal and the public, the psychological and the sociological, the domestic and the state." Thinking about the United States, for example, Mintz suggests that children and young people were "inextricably engaged" in key historical events – from "colonization and revolution to industrialization, urbanization, immigration, and war" – and that the "history of childhood is bound up with key cultural, economic, historical, psychological, and sociological themes" (Mintz 2012, p. 17). While context specific, these observations are readily transferable to a host of other national or regional historical contexts in which children have lived or participated.

With the United States also in mind, but having broader application across the Western world if not further, Mintz helpfully offers at least four reasons why histories of children and young people might be of wider significance (Mintz 2012, pp. 18–24). In the first instance, childhood history readily intersects with a number of important historical themes. Childhood, for example, is central to understanding things like: State formation (especially education and educational development, emerging bureaucratic functions, and the evolution of the welfare State), the development of consumer economies and cultures, modernization, and the rise of the therapeutic professions. Secondly, there are synergies between childhood and culture with respect to both the historical "construction of class, ethnic, gender, generational, and sexual identities" and, perhaps less easily, with "children's peer cultures" (Mintz 2012, p. 21). Thirdly, a focus on childhood helps to disrupt expected continuities between past and present; debunking, for example, golden age myths like families being more stable in the past or that in the past childhood was more carefree.

Finally, while not everything from the past is necessarily transferable to the present, there is a didactic element to be considered. This in turn prompts a key question: if childhood and youth are constructs and thus their definitions are fluid or contestable, then to what extent can modern definitions of childhood be categorically privileged, compared with those from past eras and cultures? This implies knowing more about both what children and young people once thought, and how they now think about the past. As the final section outlines, this is a critical issue for the future of the discipline.

This is not to argue that children and young people are a historically privileged group or that their histories should be considered in isolation from others. It does provide a corrective, however, to the understandable perception that history is often defined or represented in adult terms. Furthermore it suggests that childhood and youth should be treated broadly and deliberatively as integral components of any historical categories of analysis and that children and young people's historical lives are as important as any other age or group. While many examples could effectively illustrate this, one will suffice: children and migration.

Migration history is a "hot" academic topic, both pedagogically and research wise, and links directly to a groundswell of genealogical activity and interest in wider society. Until recently, however, historical experiences of migration have been represented – in print and images – largely as adult experiences. Two factors, at least, have begun to change this. One is the relatively recent scholarly emphasis on twentieth-century migration and the use of oral history as a methodology to access migration stories from this period. Adults have recounted their memories and stories of being migrants in childhood, how they experienced that process as children, and the legacies it has left in adulthood. With this comes the consequent realization that children's migration stories also exist for earlier decades and the search to find those experiences in written archives. The other factor is the series of public revelations about the various schemes of forced child migration from

Britain to new world contexts (especially Canada and Australia), from the late nineteenth through to the mid-twentieth centuries. Books, films, and museum exhibitions (physical and online) have curated both the varying experiences of forced migration and highlighted the ways in which these children have been central to prevailing discourses of class, nation, economic progress, welfare, and national consolidation. In the larger picture, children were and are integral to the experience, process, and politics of migration, forced or voluntary. Their stories of movement, dislocation, cultural negotiation, and adaptation deserve to be told, both for their own sake and because they throw a very clear spotlight on prevailing modes of thought and the consequent repercussions for people's lives.

Challenges and Opportunities

In the inaugural issue of the *Journal of the History of Childhood and Youth* in 2008, Peter Stearns argued that a "combination of exploring childhood's pasts for their own sake with an ongoing use of history to shed light on the present" could profitably "form the goal of the revitalized historical study of childhood" (Stearns 2008, p. 40). More specifically he outlined a number of key challenges: finding and hearing children's voices, addressing existing empirical gaps, and taking a more global and comparative approach. As this article shows, these challenges are now being met head on. The field is full of vitality and promise; children's and young people's historical lives are being explored in a multitude of geographical settings and in relation to a plethora of themes or issues. Even so, much of the scholarship has focused on what adults thought about or did to children rather than children's historical experiences. To move forward there are still significant challenges and opportunities for historians of childhood and youth to further consider. While these could be listed in any number of ways, there are at least two key pivot points: prevailing discourses and the nature of the field itself.

On the one hand, the emphases of and methodologies employed by historians of childhood and youth, at any one time, understandably are shaped by prevailing academic, cultural, or political discourses. This is so for all fields of historical inquiry, but perhaps more so in this instance. Hugh Cunningham notes, for example, that the field gained popularity in Western contexts due to current “anxiety about how to bring up children, about the nature of children (angels or monsters?), about the forces, primarily commercialism, impinging on them, and about the rights and responsibilities that should be accorded to them” (Cunningham 1998, p. 1195). From a global perspective, more recent depictions and narratives, for example, of children as soldiers or political refugees, along with revelations of children as forced migrants, as victims of institutional or racial abuse, and as “stolen generations,” add credence to this observation. These emphases then determine or frame to some extent where research energy is directed – albeit to address legitimate and pressing issues or gaps in the scholarship – and they serve to link academic inquiry to social discourse or to campaigns for political change.

As Heidi Morrison’s discussion of paradigm shifts indicates, however, prevailing academic discourses also influence research foci: noted here, for example, in relationship to the changing influences on childhood history of “history from below” and of feminist, gender, poststructuralist, and postcolonial approaches from the 1960s until now. Furthermore academic and cultural discourses are often interrelated. This is obvious, for example, when considering childhood and religion. Until recently secularization – as both a current social trend in Western contexts and as a consequent academic discourse – has been central to discussions about the historical relationship between Western childhood and religion in the modern era. As a historical lens or discourse, it has tended to locate religious influence more in the premodern centuries and to downplay its significance since the late nineteenth century. Once again, however, a global approach requires a different lens. Religion becomes a more dynamic element that forces a reconceptualization of how

the child-religion relationship should be considered. In this respect the “modern [Western] model of childhood does not resonate squarely with all the world’s religions, which is significant regardless of whether or not a child grows up in a secular society” (Morrison 2012, p. 117). The world has changed significantly over the last two decades, against expectations perhaps. Current trends and research all point to this continuing norm; but children are or have been central to religious practice and convictions across multiple world faiths and cultures (Browning and Bunge 2009, pp. 174–176). Here understanding the past is critical to understanding the present, and contemporary society cannot afford, perhaps, to be bound by now outmoded discourses.

On the other hand, and finally, there are both challenges and opportunities that arise from the very nature of this field, relating to the methodological and conceptual problems with respect to excavating and gaining access to children’s historical lives, in particular issues of children’s voice, agency and participation, and the types of sources that might be more or less fruitful. Stearns captures this dilemma by noting the tension between “admitting that it’s harder to get good evidence about past children than it is about past adults” and acknowledging that “most important topics can at least be approached, and overall there’s a vast amount of material available for historical work” (Stearns 2006, p. 3). This will remain a constant tension and a persistent challenge for practitioners of the field. It may be that some source types or methodologies (e.g., oral history) provide more possibilities of engagement, that some age groups (e.g., teenagers) are easier to access and understand or that different conceptual lenses (e.g., global perspectives or the history of emotions) provide new and important ways of thinking. Notwithstanding, this is a positive tension or challenge which – as the programs of conferences, the pages of journals, and ongoing blog site entries indicate – forces historians of children and young people to remain at the cutting edge of thinking and practice. If that happens, the field will remain open to methodological innovation and fresh conceptual thinking and retain its liveliness well into the foreseeable future.

changing notions of how we understand childhood – a shift from the biological understanding of immaturity to an idea that childhood is socially constructed, and through various philosophical approaches negotiated, in any given moment in a particular society. Historical, political, economical, and geographical considerations, alongside the influences of globalization and ideology, are acknowledged as fundamental driving forces of this field. Particularly in the past 30 years, many disciplines have been claiming the right to define, shape, and provide an understanding of childhood studies and to prove that their disciplinary and methodological lens leads the way for addressing studies of childhood and children. In other words, childhood studies are so broadly defined that it can be argued that any studies of children and childhood that place children within their childhoods, in the center of the inquiry, are childhood studies. Some of the key notions that make childhood studies both important and relevant are their openness, interdisciplinary, and philosophical nature.

Childhood Studies Around 1900

Childhood Studies, An Overview of

Marek Tesar
University of Auckland, Auckland, New Zealand

Introduction

Childhood studies are an emblematic concept and lens incorporating a number of approaches, disciplines, theories, and ideas about children and childhoods. This field of study encompasses both scholarship and activism and includes a philosophical grounding and thinking about children and childhoods. Philosophies revolve around the

Childhood Studies

Childhood studies center ideas, research, and activism around childhood and children, without essentializing or mainstreaming. Philosophy, in particular, contributes to childhood studies, adding philosophical thinking about children and childhood. Childhood studies enable many researchers to liberate themselves from developmental and established top-down theoretical structures about children and childhoods and allow them to consider children as social actors and to research their rights, participation, and vulnerability, just to name a few, through children's lenses. This approach is thus focused on dismantling structural ideas around children and childhoods, and re-shapes the understanding of children's power and agency, and how children can perform these notions as members of society. Thinking philosophically also allows plurality and radical openness for numerous disciplines to become part of childhood studies – sociology, philosophy, anthropology, critical psychology,

literature, architecture, education, law, geography, and other disciplines and fields – that express their claim, right, and interest to childhood studies, to add to this colorful and growing mosaic. The other notion that unites childhood studies is cutting-edge thinking that allows diverse, creative ways of considering children's issues and ideas, with children and by children. Furthermore, what connects all of these disciplines and approaches that started from re-thinking traditional sociological perspectives as a "new sociology of childhood" is the turn that came with a new orientation toward childhood and children and ideas that address children as the center of enquiry (James and Prout 1997).

Children and Childhoods

The question of when childhood starts – and when it ends – is very problematic. Different societies apply different rules and policies, which in the West are mostly based on age, such as in the UNCRC, where clear designations define children as any people under the age of 18. However, in some, more traditional, societies, the idea of maturity refers to particular skills that are relevant to a given society and culture, as the anthropology of childhood has argued (Montgomery 2013). These ideas also propose different conceptions on the construct of a child and the construction and reconstruction of childhoods. Philosophical ponderings on who is a child and what is childhood, through different manifestations, are central to childhood studies research. In the past, these concepts were very much part of the thinking around generational structuring and ordering of society. The age of children as a determinant of a child's capabilities and abilities, and associated policies, placed children within a particular societal structure which shaped their childhood. Traditional developmental psychology, with its tables and clear definitions of stages and milestones, omitted the understanding of culture and society, and of individual differences, including the complex influence of ideology, globalization, and technology. And, most importantly, it omitted the ideas of

children as social actors and the importance of children's voice, participation, and decision-making about matters relevant to their childhood (James et al. 1998).

Childhood studies are firmly grounded in history and argue that childhood does not exist in and of itself, or cannot be clearly defined, as it is socially constructed. Through the course of history, childhood has been invented and re-invented, in different times, societies, and cultures, within diverse philosophical frameworks. There are different perspectives on the history of childhood, both romanticizing and seeing/viewing childhoods through perspectives of cruelty, exploitation, and the mistreatment of children. Historical analyses often pinpoint childhoods as not defined or linear but of complex interactions of individual experiences with ideologies and notions that challenge singular and easily understandable childhoods. The two main researchers of the history of childhoods – Ariès (1962) and Cunningham (2005) – explore constructions of childhoods and portray how childhoods are negotiated through various events and philosophies and how they are connected to society. For Ariès, the argument relates to the nonexistence of the concept of childhood in our understanding of history. He examined diaries, images, texts, discourses, literature, and objects that lead him to the conclusion that up to the Middle Ages childhood had not existed. For example, children's clothes and toys, and associated economical factors that determined their production, invented the category of childhood as a particular outcome, while before this turn conceptions of children as "little adults" were common.

Philosophers such as Hobbes, Rousseau, and Locke had their own visions about children, childhood, and their education, and as Cunningham (2005) argues, their influences in Western society were tremendous. These philosophies contributed to considerations of childhood and children as worthy of attention, of a separate category, and created a clear generational separation between childhood and adulthood. As Tesar et al. (2016) argue, as a seventeenth-century political scholar, Hobbes "saw children as evil or savage, arising

from the fact that all people are born in original sin. Here, the child is in need of control and regulation, notably by the mother” (p. 170). Locke’s philosophy on the other hand characterized “childhood as empty, in that children functioned as blank slates (the fabled *tabula rasa*) that required knowledge supplied by the family and the society so that they could ultimately become productive parts of the social fabric. Here, Locke produces childhood as dependent, as the child has no natural capacities and must be ever minded and directed by parents and the community” (p. 170). However, as they argue in their piece on the philosophy of childhood, “Rousseau inverted the wild state of nature (distinguished by a state of war) asserted by Hobbes and the vacuousness of the child put forth by Locke through a depiction of the child as living in a perfected state of nature and possessing essential goodness and beneficence . . . childhoods are constructively naïve, but they ultimately require protection from the very forces that purport to nurture and develop them” (p. 170).

Childhood thus became a new, modern construct, with associated demands and markets, including babyhood, childhood, and youth, as a structural concept of human subjects that is worth investing in. However, historically, there was an invisibility of children and their childhood. As Aries argues, “in medieval society the idea of childhood did not exist; this is not to suggest that children were neglected, forsaken or despised. The idea of childhood is not to be confused with affection for children: it corresponds to an awareness of the particular nature of childhood, that particular nature which distinguishes the child from the adult, even the young adult. In medieval society this awareness was lacking” (p. 128), particularly in the Western history of childhoods. The anthropology of childhoods elevated differences in developments and histories of childhoods across cultures and societies, and reveals striking, and sometimes very subtle differences.

Current thinking and discourses around childhood studies represent and outline the complexity of this field and its diverse positioning across disciplines. The UN Convention on the Rights of

the Child – UNCRC – was passed and ratified in 1990, and the struggles for its fulfillment and particularly of children’s well-being continue, with growing concerns of economic exploitation of children and the complexities of childhood constructs in the media-driven contemporary society. Moreover, there are shifts in conceptions of childhoods that can be perceived as visible and manifested in government policies, and then subsequently in the ways that adults treat children, and shape what it means to be a child. Childhood can thus be seen as a crisis, with a “moral panic” by many scholars in the contemporary Western society observing and analyzing it, through the discourses of care, safety, and protection. Furthermore, there seems to be a prevalent focus on becoming an adult rather than being a child that shapes the constructs of childhood, including the power relations that produce and allow children’s rights to be the driver for “best” policies, to protect “ideal” childhoods. Instead of being political and participating citizens who shape their own childhoods, children become seen as a resource, and their childhoods colonized through this ideology of care. Such shifts in understandings of childhoods in Western cultures are produced within particular government rationalities. Childhood studies research thus becomes located in diverse ideological sites. Some of the key thinkers whose work has significantly shaped childhood studies are Allisson James, Adrian James, Alan Prout, Pia Christensen, Berry Mayall, Anne Smith, William Corsaro, Erica Burman, Mery Kellett, Karen Malone, and many others (Smith and Green 2015).

Childhood Studies: Themes and Topics

Childhood studies critically engage with a number of topics from multiple perspectives. One of the key topics is children’s agency, through which children are perceived as independent social actors and capable of making decisions about their lives and their ability to demonstrate this capacity in their contributions to the governance of their issues. Agency is traditionally considered

to be a capacity that belongs to adults, as rational, biologically mature human subjects. However, childhood studies contest this notion and assign, and allow, children the ability to control their own development as outlined in many cross-cultural studies and in research with and by children. To balance the power that adults have over children, it is important to acknowledge how children can have agency over their life and within society as a whole. This agency cannot be simply perceived as influencing their individual being but as shaping the collective lives of all human subjects, and the planet, especially in this time of the anthropocene. In other words, children can make a difference in social relations, social life, and the world. This is the agency that a childhood studies framework perpetuates, no matter how difficult it is and how many barriers are set by the adult governance of childhoods. Through a childhood studies lens, children and adults are not seen as binary opposites but as human subjects that interact with the world in particular ways that pursue the well-being for all inhabitants of the planet, including other than human subjects and objects. Agency is important in policy implications, where adult constructs produce childhoods and children, and in understanding the importance of children's agency in narrowing the gap between adults and children, to enhance understandings of childhood and allow benefits for all subjects, including children.

Agency can be portrayed as a sociological notion in relation to the idea of a structure. In childhood studies, this means, for example, how children can behave, have influence over, act differently, challenge and contest the established generational ordering of society, or structure an ideology. Diverse sociological perspectives, such as of Marx, Weber, and Durkheim, direct how to act in a society independently from its structures, boundaries, institutions, establishments, and wider social relations. Giddens argues that agency is always related to structure – hence his agency/structure framework relates to the notion of power. From a childhood studies perspective, agency contests the traditional socialization theory that portrays and perpetuates children as

passive subjects of adults' influences and ideas. Agency is thus the capacity of social actors to act – with agency – to impact a change that has positive effects for themselves, those around them, the society, and the planet. This idea of agency is relevant both to children and to adults alike, and allows the transformative power of these actors, and their influence on their lives, or on the conditions of any structure of societal, or minority groups. The concern of how much “real” agency and capacity children have to effect change – given the conditions of surrounding structures, the reproduction of society, ideology, culture, ethnicity, and politics involved in each situation – is one of the challenges that childhood studies work with, research, and think about (Wyness 2012).

Research with children is another important feature of childhood studies research. As social actors, children are very much engaged with research processes in childhood studies. Traditionally, research has been conducted on children, where children were the passive objects to be examined, and often exploited, as research objects for adults' benefits and to satisfy their curiosity to understand, and often also mainstream, alter, and adjust, them or their childhoods. The focus was on the problem – of correcting particular irregularities or differences, from the position of established developmental frameworks or practices. Research on children often focuses on the negative – the problem – in any kind of deviation from “normality,” as established by the adult experts and researchers. Overall generalizations result in not respecting children's individuality, cultural differences, ethnicities, social inequalities, or the ideologies within which children play and grow up. This often leads to particular representations of childhoods through stories, texts, images, and media and problematic views that essentialize childhoods.

Research with children, often referred to as using a child-centered research framework, is a shift in the philosophy of methodologies of child research. A childhood studies lens considers children not only as the focus of the research but also as subjects, actors, that directly benefit from the

research process and actively construct and reconstruct the framework. Research with children, and in recent times research by children – where children are the researchers, together with adults, where they drive the aims and develop the research questions – enables children's views to be represented and their voices to be heard. This kind of research gives power to the children over their own lives and creates a new ethical framework where children's rights are paramount – with respect to partnerships, participation, and protection and where their voice is valued through participatory methodologies. One such approach is a “mosaic approach,” alongside many other methodologies and methods that enable children to engage, to interact, and to be research subjects, rather than its objects.

Children's voice is considered to be one of the key concerns of childhood studies. Across disciplines, research on childhoods involves adult's perspectives, adult's representations, and adult's voices about children. Children's voice has traditionally been subjugated and considered to be “childish,” not important or of interest in society. Often the importance of their voice is downplayed through considerations as “cute” or “irrational.” Children's voices are often lacking and not heard, or not listened to in decision-making, in public policy and in education or in any matters that concern children directly or indirectly. The decision-making process normally involves adults and traditionally excluded children's views on society, and its governance, or did not take them seriously. Childhood studies research both advocates and performs consultation with, by, and on children's perspectives in relation to the society that is shared by the children and adults (Davies 2014).

Furthermore, children are often portrayed in policy as vulnerable and innocent. These labels remove their agency, power, and decision-making. Children's rights as ratified in the UNCRC, article 12, for example, clearly state that children should be consulted and listened to and that their voices should be taken seriously. Portraying children and their childhoods as vulnerable removes their competence and makes

them easier to govern and mold, to shape them, in the interests of the governing agencies. Vulnerability thus perpetuates the notion that children are innocent and require protection through these agencies and removes the power and influence of children over their own affairs. In that sense, the statement “in the best interest of a child” is contested, and childhood studies research questions whose “best interest” is really being considered: according to whose definition and from whose perspective. The discourse of vulnerability is thus often seen as a way to normalize childhoods, and childhood studies contest, and argue, that as a concept of poverty and welfare, vulnerability is determined by ideology, history, politics, and economics. What constitutes these notions – vulnerability, protection, and innocence – when they are socially constructed as childhood itself is? Childhood studies in this sense attempt to debunk and challenge representations of childhoods that remove agency and power from children's lives and that portray children as dependent, lacking competency, and that normalize them in their development.

Further topics of childhood studies research include spaces for children and children's places. There are many discourses about children in urban and rural areas, on children's play and games, on constructions of playgrounds as oases of childhoods, and also on removing children from the streets. Urban planning is traditionally done for adults, without children's consultation or perspectives, and usually, the younger the children, the less consideration there is for their needs. The focus of urban planning is largely on protection and safety, with little participation of children and young people in urban designs. Child-friendly initiatives utilizing childhood studies discourses contest the notions, for example, of rural idyllic lives and “desperate” and “suffering” childhoods in the city, and instead portray opportunities for including children in decision-making, seeking their perspectives and ideas about life in the city and its societal structures. Needs and interests for children can be considered as such only if they are articulated by children, not by their parents and other adults.

Future of Childhood Studies

Childhood studies is a growing field of interest with much international conferences and continuous scholarship and activism. The idea of childhood studies as an interdisciplinary field is flourishing, particularly in the past 30 years, and is experiencing new, unexpected disciplines and turns, from its “new sociology of childhood” framework (Prout 2005). Philosophy is one of the disciplines that adds important scholarship to the notion of childhood, including the challenge of discursive and social constructions as the only way to understand childhoods, by including the lens of posthumanism and new materialism. Cutting-edge methodological thinking in childhood studies has its grounding in using philosophy as a method, in child/animal relations and in notions of the anthropocene and sustainability. The importance of childhood studies is that it is not dominated by one discipline. Interdisciplinary thinking and relations and philosophy – as it seems from the entries in this encyclopedia – will play an important part in the future of childhood studies.

Introduction

Early childhood education methodologies have gone through philosophical upheaval and various ontological and research design related changes during the last decades. First epistemological and later ontological shifts have brought into attention childhoods as epistemologically instable structures, always already suspect for questioning and fertile ground for deconstruction often highlighting subject as decentered and children as connections within more than human assemblages and fields of relations. These shifts have altered the ways in which early childhood education is being theorized, studied, and researched.

Early childhood education, similar to many other fields, has gone through philosophical upheaval and various ontological and methodological changes. For example, the authors of *Reconceptualizing Early Childhood Care and Education* described how the dominant positivist theoretical perspective common in the USA and other countries began to be challenged in the late 1970s and early 1980s by critically oriented psychologists, sociologists, and cultural anthropologists (see Bloch et al. 2014). These critical scholars and many others began to question, specifically, the confirmatory or exploratory perspectives that looked at the “what ‘is’” rather than “what might or ought to be.” Through their questioning of fixed educational practices and normalizing childhood discourses, radical scholars focused on power relations, identity politics, and various forms of exclusion and inclusion using methodologies grounded in qualitative,

interpretive, and critical traditions. At that time many scholars who desired to reconceptualize early childhood education drew from critical curriculum theorists and the Frankfurt school's forms of critical theory exploring a range of issues including the content of early childhood curriculum, play, and work promoting class inequalities as well as relations among the States, economy, parenting, and education. The 1990s and beyond have brought yet another set of changes into the methodologies and theorizing of children and childhoods. First epistemological and later ontological shifts have brought into attention childhoods as epistemologically instable structures, always already suspect for questioning and fertile ground for deconstruction often highlighting subject as decentered and children as connections within more than human assemblages and fields of relations.

To reflect these ontological shifts, think beyond existing theoretical and methodological practices, and to move toward theories and methodologies of becoming, movement, and fluidity, we introduce one way to approach the question of method, methodology as an ongoing "post-project" and area of reconceptualizations within early childhood studies. We view these "methodologies" as continuous relational decisions, movements, performances, and onto-epistemological events that matter to those interacting with children and constructing different forms, copies, and differentiations of children and childhoods. These movements are especially important in light of neoliberal policies and practices that have further promoted post-inquiries and many post-perspectives (such as postmodern, poststructural, postcolonial, post critical, post human ways to conceptualize our worlds and so on) as counter measures to increasingly narrowing notions of childhood. To signal this onto-epistemological shift, we extend the label of methodology itself. The post-inquiries mark spaces and places as well as ontological systems that question the existence of fixed researchable world, validated research techniques, and systematic tools to produce scholarship.

Methodological practices as post-moves and continuously shifting reconceptualizations bring

forward various potential ways to extend dominant, rigid, and close-ended research approaches and to problematize the role of generalizable scientific method. However, it is important to acknowledge that even though we decided to use the term "methodology" to engage with broader methodological discourses, we find this term and concept increasingly problematic, and as such it calls for serious creative and practice-based departures. Extension markers in the label "methodology" speak to many possible and still unrecognizable ways to live through methodology differently without giving up the label itself or its historical presence while simultaneously resisting this label's normative linkages, associations, and doings. Our extension markers not only take the known concept and generalizable methodological practice apart, but they also generate multiple in-between spaces, lines, and connection junctures where becoming methodological differences can be lived through and possibly recognized or sensed.

Based on always already limited review of literature and current discursive formations available to us in different fields of early childhood studies, we found current and contemporary methodologies of children and childhood both dispersed and centralized. In recent years much of the innovative methodology at work has taken place in Australia, North America, New Zealand, and northern parts of Europe. For example, preschool environment outside classrooms, alternative childcare centers, bathrooms, playgrounds, forests, animals, online spaces, media, art, children literature, workplaces, policy documents, and objects such as dolls and stones have inspired many contemporary scholars to think more creatively and critically how children are constituted as subjects or performances within various material-discursive spaces.

Furthermore, we argue that ontological shifts call for creative and experimental methodologies that are not stuck in the methodological past but are capable of visioning various different methodological futures and new performative methodological linkages. Methodologies form fluid and becoming structures that extend processes of knowing and being, thus shaping experiences,

senses, and affect (see Koro-Ljungberg 2016). For example, theoretical and relational extensions push the onto-epistemological boundaries of methodologies. The methodological question is no longer how to study children and childhoods in separate, developmental, and individual contexts but how children and childhoods are constituted and positioned in the world, how childhoods function, and how children relate to the Other in a continuously changing world of relations, power, and more than human. Rau and Ritchie (2011) provided detailed examples of these complex cultural positionalities, policy documentation, and relations to power in looking at the Māori tikanga, the culturally specific ways of knowing and doing that are both culturally right and children's right. Ethics, language, tribal identities, spirituality, traditions, voices, and sacred pathways were used to transform Western trajectories for Māori children.

Instead of studying children and child "objects" through clinical and clean observational methods, some contemporary childhood scholars engage in collaborative and material activities that not only critique existing knowledges and practices but also offer and document alternative engagements and entanglements of children in their complex worlds. Methodologies function not as nouns but as verbs and continuous processes of modification and variation. For example, scholars reconceptualize, re-entangle, untangle, liberate, queer, problematize, understand, compare, sustain, relate, negotiate, clock, and guide children in their discursive material contexts. These purposeful engagements might not be carried out in teacher-led classrooms, constrained and adult-created spaces, or through predetermined research designs. Instead, data have been reconceptualized as air, assemblages, interaction between discursive and material forces, events, encounters, memory, desire, intensity, interactivity, dialogue, technologies, and animal-human relations among others.

Next we share five different potential methodological extensions that could transform current normative methods and methodologies and as such could speak to methodological assemblages yet to come. First, *theoretical extensions* will highlight various forms of theoretical and

epistemological hybridities in early childhood scholarship. Second, *spatial extensions* move scholars toward mess and nonlinear methodological spaces, whereas *ontological extensions* bring forward the material and more than human in children's lives. Third, *linguistic extensions*, in turn, trouble both methodological language and the language often taken for granted in the context of children and childhoods. Finally, *historical extensions* enable methodological assemblages that bring methodological historicity and epistemological ghosts to our everyday encounters.

Bringing different philosophies to the processes of inquiry and using existing processes to expand contemporary theories, multidirectional connections can be reestablished between theoretical concepts, ideas, and children who live in a more than human world. This relationality also recreates and reestablishes inquiries and methodologies as ethical and responsible practices. Thinking with theory (see Jackson and Mazzei 2012) and theoretical sensitivity has become a meaningful goal and useful practice for many scholars in the field of childhood studies. Thinking with theory brings methodology and philosophy together in purposeful and practical ways. This type of fluid and unanticipated zigzagging between theories and research practices is likely to open up new epistemological dimensions and proliferated encounters within the children's complex worlds. In addition, for many early childhood scholars theoretical or conceptual exercise per se is not enough but critical, Chicana feminist, new materialist, and post-human scholars call for research processes and methodologies that have potential to impact policy, change environments, illustrate and demonstrate policy's limitations and insufficiencies, and to promote change in early childhood communities and practices.

Furthermore, theoretical and conceptual hybridity enables scholars to draw and highlight multiple perspectives and approaches at once. Adaptation of a hybrid orientation also speaks to the diversification of knowledge while simultaneously avoiding traps of essentialism and foundationalism. For example, some early childhood scholars might use Foucauldian scholarship in conjunction with Deleuze and Guattari,

whereas others could utilize a set of concepts or theoretical arguments from Derrida, Havel, Giroux, and Marx or locate their work alongside Barad and Haraway. Many scholars today draw from postmodernism, poststructuralism, socialism, post-humanism, feminisms, human geography, ecology, and geography as well as from indigenous epistemologies and theories (especially Māori worldviews). These perspectives offer alternatives to the over-humanistic, developmental, and cognitive child concept and often human-centered care practices. In addition, hybridity is often accompanied by careful attention provided to various ethical issues such as autonomy, responsibility, agency, relationality, silent orders of things, ecologically sustainable living, and ethical more-than-human interaction. We see this interaction in the negotiation for ecological sustainability practices and pedagogies of place in early childhood centers in New Zealand (see Duhn 2012). Duhn framed the current discourses of critical perspectives in early childhood education situating them within “nature-culture,” material, place-based education, and teachers’ emerging pedagogies of place. Children’s sustainable care for the environment was based on ethical and carefully crafted relationship between the “local” and “global.”

Spatial extensions of more or less fixed methodologies could be accomplished through fluidity,

mess, and creating space for the unanticipated. Fluid methodological spaces and methodological multiplicity might involve the coexistence of methods, perspectives, images, theories, frames, and subjectivities all potentially present at a single moment. In fluid spaces normality is an increase in the magnitude rather than a cutoff or end point. Additionally, in fluid methodological spaces, methods and research approaches melt, transform, circumvent, infiltrate, appear, and disappear. The desirable mess in methodology has been discussed, for example, in the scholarship of John Law and Patty Lather. Both Law and Lather embrace the always already existing presence of mess, the disorganized order of mess, possibilities of the mess to prompt and stimulate difference, and risk taking associated with nondirectionality and complexity. Unsettling, upturning, and stimulating examples can be seen in the work of Nxumalo (2012) where she seeks to disturb the static representations of difference and diversity that have sprung from multicultural pedagogical approaches. She does this by using the material-discursive becomings to show relationality while exploring what micropolitical possibilities and significant everyday encounters traditional coding might miss. Interestingly, rather than cleaning up various interferences and interruptions during children’s clay-water encounters, messy processes and material methodologies produce insights and forces that pulsate and move the mass of mess to various different directions simultaneously. Nxumalo’s data vignettes illustrate relational ethics, and they portray how clay-water and girl-child-body become with and mutually transformed when children experiment with brown clay-water on skin. More generally speaking, the methodological benefits of mess might have to do with breaking boundaries, opening up new directions for research, combining methods and theories, blending human and more than human, and creating new language that materializes through and lives within and alongside the mess. These types of methodologies need to breathe, adapt, and live with and through their users.

Ontological extensions enable scholars to rethink anthropocentrism and ways to decenter the human. For many scholars in early childhood,

agency and consciousness are not uniquely human prerogatives but can also belong to matter and objects in the more than human world. Baradian space-time-mattering offers one opening to think about ontologies of children and childhoods differently. Lived and sensed materialities of childhoods counter and extend psychological childhood discourses. For example, children are no longer exclusively studied as cognitive learners or obedient students, but they are seen as multifaceted discursive, gendered, artistic, performative, spatial, bodily, sexual, intra-active, agential, and rhizomatic “subjects” constituted by and within various discursive material practices and power relations. Materialistic, artistic, and performative ways to construct and process knowledge enable scholars to construct meanings as ongoing performances of the world. Methodologies of children and childhoods can be seen as differential responses and responsiveness in the network of performances. Scholars no longer speak of isolated methods but series of intra-actions, relational fields, networks of actions, and matter, opened practices where humans and nonhumans are constituted in differentiated and continuously changing ways. Methods are conceptualized as diffractive methods, artistic and performative methods, and many other creative and expressive practices of doing and acting. Within these perspectives, methodological focus shifts to patterns of difference during entanglements, emerging of subject and object through intra-actions, differences, and expressions matter. Scholars account how matter, matter and artistic, and kinesis sensibilities guide participants’ inquiries and interactions with the world. Furthermore, artistic and performative inquiries offer flexible architecture for theory and concept building. For example, Kouri and Smith (2013) show how opening up to ontologies of wonder and creativity can make room for creative and performative methods. By asking “What’s under the dirt?” Kouri and Smith bring ontological questions and wonderings to children’s everyday encounters. Without focusing on answers wondering-with becomes a tool for inquiry and a space for critical reflection simultaneously offering possibilities to think about inquiry differently.

Linguistic extensions trouble and erase language making discursive spaces for new or alternative linguistic expressions and ways to communicate. Methodological language and labels are situated within a particular time, space, and cultural context and as time, space, and contexts morph and shift, so do linguistic extensions. Linguistic extensions can be put forward as epistemological markers, ontological reference points, and personal preferences, and they can also be used as means to legitimize one’s scholarship. For example, some interesting concepts found in recent early childhood literature included response ability, post human landscape, common world, unruling stories, cosmopolitan imaginaries, autotelic material practices, deer/settler-child figure, post human packing and packaging, and clocking practice. For example, Pacini-Ketchabaw (2012) focuses on mundane practices and stories of deer/settler-child figures. Deer/settler-child concept is used both metaphorically and materially as ways to mark specific types of postcolonial relations between a deer and children in Canadian daycare center. Furthermore, this notion of cross-species encounters might also help scholars to better understand pedagogical and ethical issues that divide and subjugate in other settings. As a result, language that defines those setting may no longer apply but needs to be rethought and recreated.

Lastly, some historical extensions can also be visible and present in methodologies of children and childhoods. For example, ghosts of the methodological past (practices) such as content analysis and comparative analysis are used and mixed with neoliberal discourses and practices. Studies are being labeled as exploratory to differentiate from large generalizable and quantifiable methodologies. Practitioner research is separated from research carried out by academics, and ethnographies are used to observe and document “foreign” and “distant” cultures. In these habituated environments, concepts like academic readiness and standardization are both used and challenged. However, rather than continuing in the vain of social reproduction, these concepts are also being explored and extended by scholars who see themselves as transformative intellectuals

and agents of change. In these cases, historical methodological ghosts do not repeat the methods from the past (as they might be designed to do), but they provide present diversifications and extensions which are never identical to the past. For example, Brown and Wright (2011) used content analysis of five media prints to investigate the role of media in the public pre-K movement. In this study political spectacle theory was used to challenge potentially linear and quantifiable insights gained from a content analysis. Political spectacle theory opened up themes, narrations, and new analytical questions to illusions, staging, and disconnections.

Derrida viewed ghosts and haunting as a necessary element in every hierarchical structure and historical systems. Haunting and ghosts of normative methodological past appear unexpectedly and their impact and influence is impossible to predict. We envision that a ghost has a virtual, absent body and thus is also absent presence. Ghosts are with us but they are not in their physicality. Past learning (memories, senses, images, texts, etc.) shapes the presence, and absences (things unlearned and lives not lived) are always present. Derrida (2006) argued that it might be always necessary to learn spirits and ghosts. He encourages us to involve ghosts in our learning, to live with ghosts and in their companionship. This learning through living with ghosts would also involve working through cultural and pedagogical inheritance and engaging with the politics of memory.

How could one envision the becoming methodological assemblages beyond these suggestions and ideas? There are no simple answers only many more unthinkable extensions beyond the ones shared here. Thus, it is not our intention to list all possible extensions or exhaust different dimensions of methodological assemblages since these moves will close up and restrict methodologies of the future and becoming. All methodological extensions are always limited and partial and yet can be dangerous since they are often in some ways tied to humanistic knowledge projects and normative ontological obsessions and desires. Through collaborative experimentation and continuous collective reflection, scholars might be able to work through voids, extensions, and

spaces of uncertainty, always moving and shifting the methodological, utilizing slow and quiet motion. Multiple worlds, contextual enactments, differentiating sites, fluid findings, shared spaces, elusive objects, slippages, nonconventional forms, mystery, resonance, imagination, creativity, and surprise could serve as proxies for methodologies to come.

Children and Objects

Casey Y. Myers

[Material culture](#), [Artifacts](#), [Materiality](#)

Introduction

Objects, for the purposes of this entry, are defined broadly as nonhuman, nonliving things. The significance of objects in the lives of children has been an active area of interest within childhood studies for several decades; the theoretical and practical focus of which has largely mirrored broader turns in social science. That is, as the field emerged within the cultural turn, children and objects have been understood primarily through a sociocultural, rather than a psycho-developmental, lens. This is reflected in ways in which children's relationships with objects are woven throughout well-established areas of interest within childhood studies – most notably examinations of consumerism and material culture. As the social sciences are in the midst of a material turn, children and objects are currently emerging through a new materialist framing.

Products for Children

An abundance of sociological literature (and perhaps to a greater extent popular social commentary) has focused on the relationships between children and the objects that are produced by adults specifically for their *consumption* – toys, books, video games, and other branded media. Positioning children's relationships with objects as one of consumption reveals familiar polarizing tensions between discourses that either frame children as innocent victims or as savvy participants. In the former, objects for consumption are borne out of corporate greed, and both children and childhoods are subsequently corrupted by these objects. This corporate infection of childhood brings with it a litany of negative educational, social, physical, and moral effects that are of concern to well-intentioned adults (Jones et al. 2011; Schor 2004). In the latter discourse, however, children and their specific cultural ideals drive the production of media and any associated products; corporations are simply giving in to the desires of children-as-customers and childhood-as-emerging market. A critique of these either/or discourses, tied to persistent notions of childhood

purity and fragility or childhood agency and hyper-autonomy, is that they ultimately fail to adequately capture the complexity of the ways in which the individual and collective identities of children exist in reciprocity with the objects of their consumption (see Buckingham 2011, for a thorough review of these tensions). It has been argued that more balanced conceptions of children and objects in relation to consumption might, rather than position commercial products as either inherently bad or good, work to understand the various ways in which objects are implicated within the inseparable phenomena of consumer culture and childhood – that toys, video games, and other products exist within a complicated matrix of children's peer and familial relationships, children's and their parents' desires for normalized participation within peer culture, and market forces driving creation and production of objects for children's consumption (Pugh 2009).

Artifacts of Childhoods

A material culture approach suggests that objects exist as artifacts of both childhoods-as-perceived by adults and childhoods-as-experienced by children. As noted in the previous section regarding consumption, adults produce many of the objects with which children engage (e.g., mass-produced toys). These objects may be conceptualized as artifacts representing what adults perceive children to want, enjoy, or need at moment of production. As such, objects produced by adults for children offer physical traces of childhood as an *adult* construct (Brookshaw 2009). Similarly, collections of artifacts for the purposes of “studying, preserving and representing the lives of children in the past through their material culture” (Pascoe 2013, p. 234) often present a history of childhood as constructed by adults. Once again, there are tensions present in what these artifacts represent about the particular qualities of childhood. Studies of these artifacts, typically undertaken through examinations of both private collections and curated museum exhibits, reveal a range of portrayals – from universalized and nostalgic

childhoods to more nuanced and complex accounts that aim to disrupt idea(l)s about who children were and how they experienced life in past eras (Pascoe 2013).

In terms of childhood-as-experienced, conceptualizing objects as artifacts assumes that children preserve intangible elements of their lived experiences within tangible objects. From this perspective there is an assumption that “much of children’s lives is hidden...and artifacts from that hidden life can help illuminate it” (Graue and Walsh 1998, p. 123). To this end, the “hidden” aspects of children’s lives tend to be conceptualized as experiences of play, schooling, and peer relationships, as these areas have been of particular interest when studying children’s artifacts from a material culture perspective. For example, objects that children create or construct themselves may serve instrumental purposes within the complex games and play rituals in which they participate, and objects can also serve symbolic, semiotic purposes within peer relations as children inscribe objects with sociocultural values, such as friendship or social status (e.g., Rossie 2005).

Children and Objects as Mutually Constituted

While the rejection of reductionist psycho-developmental discourses about children and childhood has been foundational to the childhood studies movement during the cultural turn, it has left childhood objects as decidedly inert recipients of sociocultural inscription (e.g., as symbols, representations, instruments, etc.). Following the more recent material turn in social science, enactments of childhood studies from new materialist perspectives have departed from strictly sociocultural framings of child-object relations and moved toward conceptualizations of childhood wherein subject-object hierarchies are flattened and boundaries between human and nonhuman are blurred (see Lenz Taguchi 2010). From this perspective, objects are not merely passive things onto which human values are inscribed, but are active agents in the production of childhoods. Children and objects do not precede their relations

with each other, but are mutually constituted. Thus, childhood is produced in the moment of child-object intra-relating *and* produced differently in each encounter, creating “spaces of open-ended and de-individualized knowing and being” (Rautio 2014, p. 274). Instead of determining the representational qualities of objects in relation to children, scholarship in this vein works to decipher what children and objects do to each other; how they are continually working upon each other through evolving encounters of invitation, exploration, transformation, and invention; and how material relations matter to children (Rautio 2014). In these ways, emerging new materialist scholarship within childhood studies is working to attend to the heretofore “excluded middle” (Prout 2011) of childhood materialities – wherein children are produced within a set of material relations and objects are produced within a set of childhood relations, neither of which can be meaningfully separated from the other.

Children and Punishment

James D. Marshall

The University of Auckland, Auckland, New Zealand

In his legal model of punishment, Hart identified a number of conditions which had to be met for the correct application of the concept of punishment. For an application of the concept of punishment, these conditions had to be met (Hart 1968: 4 f.):

1. It must involve pain or other consequences normally considered unpleasant.
2. It must be for an offense against legal rules.
3. It must be of an actual or supposed offender for his offense.
4. It must be intentionally administered by human beings other than the offender.
5. It must be imposed and administered by an authority constituted by a legal system against which the offense is committed.

In considering his legal model of punishment, Hart drew a distinction between standard cases and substandard or secondary cases of the use of punishment. For the accolade of standard to be applied, all five conditions listed above had to be met. Substandard cases were illustrated by Hart by the following cases or possibilities: pain or consequences for breaching other than legal rules (here he gives, as specific examples, the family and the school); by other than authoritative officials; and unpleasantness or pain imposed deliberately by authorities but upon non-offenders. This presents something of paradox for educators

over the meaning of “punishment.” How can we talk meaningfully, in more than a substandard sense of the term “punishment” and more than metaphorically, about the punishment of children? The conclusion which must be drawn from Hart is that if we accept these conditions as part of the meaning of punishment, i.e., as necessary for its correct application, then the use of “punishment” in relation to young people in home or in school is a substandard or metaphorical use of the concept.

There are other problems with these conditions. First the punishment of children may not necessarily involve pain or unpleasantness (condition 1). For example, after an event involving thoughtlessness, a child may be punished by telling her or him to go and do something which they enjoy. If the punishment involves exclusion from the parent which, under the circumstances, may be a relief for the child, it also carries with it pleasantness. And psychologists in their approaches to punishment talk of both negative and positive rewards. This would be an example of a positive reward. In a psychological talk, this example would be a positive reward and not unpleasant.

Neither Flew (1954) nor Peters (1966) accepts Hart’s restriction of rules to legal rules and extends the notion of a rule to cover the quasi-legal status of school rules. Clearly that reduces the force of Hart’s stronger claim on rules, but there are problems with the status of such rules. Can they be just any old rule? For example, the British philosopher Mary Warnock has argued that it does not matter what school rules are but that there must be rules (Warnock 1977). Thus, the emphasis is not so much now on right behavior and being initiated into adult forms of life where there must be some form of rules. Instead the emphasis has become on rules and following rules, whether or not those rules are rational or suitable for young developing human beings. What seems to be sought is discipline per se and not necessarily discipline for the right reasons. There is little doubt that adults must follow rules, but hopefully they follow those for the right reasons and not just because they are rules. Any punishment system based upon Warnock’s

conception of school rules and which attempted to justify punishing children because it introduced them, or initiated them, into the “real world of life” (Wilson 1971, 1977) would therefore be highly suspect.

Second, if the rules are not legal rules then, for breaching such rules, adults do not get punished – scolded, verbally abused perhaps, but not punished (except in a very attenuated secondary use of the term). Therefore, adults and children seem to be treated differently. What talk then of initiation into adult life?

In condition 2 there is a talk of an actual or supposed offender. But innocent children are punished in group situations (and arguably for good reasons), and no offense may have been committed when a child is punished for a totting up of a number of “close offenses” in those “trying on” situations with teachers in which the young often indulge. Second, children who have committed offenses are sometimes not punished, because for some reason, and often properly so, they may not be considered “ripe” for punishment. But then on adult terms, questions of fairness and justice must arise – why are only some children punished for offenses? Does this mean then that whatever happens to the young in the name of punishment may really be something different? Does it mean that the real world for children is not just and fair?

The talk of self-punishment is not obviously meaningless (condition 4) as, e.g., flagellation was a common enough practice. Nor is it uncommon for us to forgo pleasant things when we have done things which we regret or which were unpleasant. For better or for worse, such practices exist and are learned and applied by children.

Finally there are problems with condition 5. In his account of the punishment of children, Peters (1966) discusses several closely related concepts, namely, “discipline,” “authority,” and “punishment,” opening his account with a discussion of authority. Peters believes that he can extend the notion of a rule in Hart’s account because he conceives rules as rule-following in Wittgenstein’s (1953) sense. But this is a serious mistake because he misunderstands Wittgenstein’s notion of rule-following.

According to Peters (1966, p. 237) “the most crucial concept for discussing social control in the school is that of authority.” But in his account of authority he is clearly drawing upon a reading of Wittgenstein on rule-governed behavior, conceding to Winch (Peters 1966, p. 246) that authority is necessarily linked with rule-governed behavior; in Wittgenstein’s sense, authority then:

presupposes some sort of normative order that has to be promulgated, maintained and perpetuated . . . (by) . . . procedural rules which give such people the right to decide, promulgate, judge, order and pronounce . . . (it) would be unintelligible unless we first had the concept of following rules with the built in notion that there are incorrect and correct ways of doing things. (loc. cit.)

Peters seems to interpret Wittgenstein as seeing rule-following behavior, as requiring submission to rules, as if rules were commands from authorities. A similar interpretation is made by John Wilson (1977). There is too much of the command sense of a rule here which, e.g., Kenny (1975) says, is a misunderstanding of Wittgenstein.

In the school then, according to Peters, authorities pronounce upon the rules (interpreted in Wittgenstein’s notion of rule-following behavior), and are the authorities which in turn administer discipline and punishment (though for Peters punishment is a necessary evil – in contrast to John Wilson who holds that it is in some sense logically necessary – see Marshall 1984a). However, Peters has smudged the notion of a rule from its legal sense in the Flew-Hart-Benn model by construing legal and school rules as rule-following in Wittgenstein’s sense. But there are further problems with authority.

If adults do not like the existing authority structures, they have legitimate grounds for redress, at the ballot box or by emigration. Authority relations presuppose then a certain independence and autonomy on the part of those who submit or accept authority. But this cannot be the case with the young. They have no option but to accept or submit to the authority of adults, though there are clearly ways in which the young can be protected from the indiscriminate use of authority or abuse by parents and teachers. Thus, the normal relationship between parent and

child is not quite that of the legal and rational notion of authority presupposed in condition 5. It is more like a power relationship which can of course be benign and positive, as opposed to negative and oppressive.

Finally however there are issues of responsibility. Adults are not punished if they are not responsible for their actions. J.S. Mill in *On Liberty* was quite clear that children lacked responsibility and should not have the freedom which Mill prescribes in this famous text. Of course there are problems of the age at which children can be held responsible for their actions, but it is quite clear that the very young are not responsible. It is also quite clear that things are done to them in the name of punishment. My case is that this is misdescribed and that there is some conceptual confusion.

In conclusion at this stage, then we can say that there are problems with all five conditions of the Flew-Benn-Hart-Peters model of punishment in trying to apply it to children. When we turn to consider how punishment of children can be justified by the traditional theories, we meet a similar raft of problems.

The retributive theory involves a paying back for a crime committed in the past. But this backward-looking justification would not be very helpful if our concerns were with morally educating children, which must be a forward-looking enterprise. Nor is it obvious that young children who look responsibility have brought evil into the world. Is unpleasantness the sort of thing which we wish to inflict upon children? Apart from moral disquiet, here the psychological "evidence" may be no.

With its forward-looking emphasis, the deterrent theory looks more hopeful. Certainly we do not want young people to continue with aberrant behavior. But, even if young children are disposed to do *X*, and it is not obvious that they are, it is even less obvious that we should be threatening them (Contrast John Wilson (1977) who sees punishment as the necessary outcome of an offence.).

Why do we wish or need to threaten children, offenders, and the innocent others in this manner? Some people believe that children are born evil, but if one believes that they are born neither good

nor evil, like Rousseau, then the need for such threats would seem to evaporate. Instead, as good or evil children are the outcomes of their environment, we should look at restructuring our social environments.

Conceiving the justification of the punishment of children as reform also has an attractive appeal.

Reform involves the "bringing back" to the path of goodness, someone who has seriously strayed and lost their way. But this serious straying from the path is not compatible with views of innocence often held about children and hence with what path they are on and other beliefs about childhood being a time for making mistakes. These views relate to other views about the understanding by the young of what they are doing and the long-term effects of their actions. In what sense then have they strayed and in what sense are we bringing them back? We may need to change or redirect the behavior of the young, but reform does not seem the appropriate term.

Finally, A.C. Ewing (1929) talks about an educative function of punishment. He emphasizes the importance of getting the young into good habits, realizing that it is often more important to get the very young to refrain from certain behavior and habits, simpliciter, than to refrain from those behaviors and habits from the best motives and the best intentions. Hopefully that can and will come later. Good habits are instilled in children, according to Ewing, by, first, fear of the consequences and, second, because of the "emphatic condemnation of a teacher or parent whose authority they respect" (Ewing 1929, p. 92). Ewing also says that in instances of punishment, the accompanying talk, in a rational manner, helps "din the words in."

It would be simplistic to dismiss Ewing's "educative role" of punishment of children by recourse to attack upon the notion of deterrence, although that would be possible. Here the arguments would focus upon the deterrent notion of punishment, which is inherent in Ewing's notion of the educative function, and upon there being merely a contingent relationship of understanding. This would make the educative justification no stronger, philosophically, than the retributive or deterrent theories. More positively, in the Ewing account, it is clear that adults can have the words "dinned in,"

more or less. But children? How can words be dinned in? How do young people conceptualize these issues and the relationships between what they “did” and more general abstract principles such as fairness or love so that the words can be “dinned in”? What sense does “dinning the words in” make without certain conceptual understandings? Therein rest many issues raised by educators such as Piaget and Kohlberg, who talk of stages of moral “development.” If their claims about the stages of development of moral understanding and, thereby, conceptual levels of possible understandings of words (and moral notions) are correct, then how can punishment and “dinning words in” work with our young at their various alleged stages? If the required understanding is not that of the conceptual level attained by the young person, then there is no possibility of “dinning.”

In general summary then, with applications of these theories to the punishment of children, we must ask: First, do we really wish to take retribution upon the young? Second, do we wish to deter, if not threaten the actions or behavior of young people, when they scarcely understand what they may be doing? Even if they did, do we really wish to pursue the general deterrence of the young? Third, do we wish to talk at all about the reform of the young when we talk about reform concentrates upon those who have willing and knowingly fallen from “grace,” which is not obvious in the case of children? And, finally, how can we talk about punishment involving the education of the young when their very capacities to understand reason are denied by the notion of reason itself – that is, children are not normally considered to be rational (at least by some philosophers, e.g., J.S. Mill)? If it is far from clear as to what being rational involves, and at what age the young are “really” rational, the law adopts a number of positions in relation to the young concerning when they may be considered to be rational before the law. These positions on age of responsibility vary considerably.

Of course a Wittgensteinian response would be that the search for “the” concept of punishment is of course misleading because “punishment” is used in a number of ways – for the cases of criminals, children, boxers, and dogs, to mention

a few. There is a family resemblance between these uses which we learn and apply in practice, and there is no one sense, or logically prior sense of “punishment.” In addition Wittgenstein would be concerned by the notion of a theory of punishment, concerned as he was by all attempts to formulate philosophical theory.

Can we justify the “punishment” of children? If what is sought is a general theory of justification, the answer which will be given is “no.” However particular cases may be justifiable. So far we have discussed concerns about the applicability of the traditional justifications of punishment to the children. But at best at this stage, it may only be to make their application to the case of children problematic. However if we are to justify punishing children then, the following points at least need to be considered:

1. Children need to acquire good “habits,” and they need to be prevented from doing certain things, the outcomes of which might involve physical or psychological harm.
2. Children, especially very young children, may not understand the reasons for and against certain behaviors.
3. Nevertheless reasons must be offered, and children encouraged to think about their behavior.
4. There are problems about the nature and status of rules which children are expected to follow and the nature of the authority relationship between adults and young children.
5. Sometimes the non-guilty may need to be imposed upon (children and group punishments).
6. The punishment of a child is essentially a discriminatory matter for that child. Only certain children may need punishment.

When we consider these features, the notion of a general justification of the punishment of children seems quite unclear. What could it look like? Children must acquire habits for their preservation, but how is the acquisition of “good” habits to be developed rationally? What counts as fairness in the punishment of children? How are the non-punishment of the guilty and the punishment of the innocent to be justified? How would it

compare with the punishment of adults? It is not only that the concept appears different but that also a new form of justification is needed.

The assumption in Western societies has been that there is a general justification, but this needs to be called into question (see further, Marshall 1984b). My position would be that there is no general justification for the punishment of children and that only particular justifications in individual cases are possible. Thus in each case of the punishment of children, the justification must be made because a general justification of the punishment of children cannot be presupposed in advance (as it is for adults in the legal system). In other words the onus of justification is on those who wish to punish children – the moral high ground should rest then with those who are opposed to the punishment of children. That is of course to reverse the general presumptions that underpin our existing practices, where in general the high ground has rested with those who do punish.

Children and Sustainability

Karen Malone

Centre for Educational Research, Western Sydney University, Penrith, NSW, Australia

Synonyms

Childhood and environments; Education for sustainability; Environmental education; Sustainability education

Introduction

Whether growing up in minority or majority world nations most children engaging with concepts of sustainability in the twenty-first century will be living in urban environments. In this highly mechanized urban world where humans have positioned themselves as exceptional or exempt to impacts of human activities, there is a considerable amount of debate and discussion on the definition of sustainability and how it will address the issues facing humanity. Measuring the acceleration of human impact including climate change, biodiversity loss, extinct and endangered species, and toxic contamination of environments has been reported as evidence of the Anthropocene. The notion of the Anthropocene coined by Noble prize-winning scientist Paul Crutzen compels us to consider humans as a new geological force, a new epoch in the history of the planet where humans have now irreversibly changed the planet. What this new epoch does is call “into question the sustainability of life on earth as we know it, including the survival of our own species” (Taylor and Pacini-Ketchbaw 2015: p. 509).

Sustainable development is often perceived to be mainly associated with the nonhuman environment. However, taking a broader focus on the issue leads to considering how communities, locally and globally, can meet the needs of humans and nonhumans, to achieve development that can be both sustainable and be sustained. This

means continuing to address issues of poverty eradication, human rights, and equity while also realizing the need for more sustainable patterns of consumption and production, calming climatic forces (UNICEF 2012, 2013), and attending to our relations with the more than human world. Urban growth and sustainable development may not seem like compatible partners, but if human populations do continue to grow at the rates predicted, then cities might be the only way the planet will support a sustainable future. That is, high-density urban environments will be the most cost-effective and sustainable way to accommodate and provide infrastructure to the billions of new human inhabitants and endeavor to provide places for nonhuman beings to also coexist (UNICEF 2012). Considering the enormity of this task, it is often easy for the role children have in sustainability to be overlooked and dismissed. This entry will focus addresses how children have had and will continue to have an essential role in issues of sustainability.

Defining Children and Sustainability

There are many definitions of sustainability, and it can be better understood as an emerging vision rather than a neatly defined concept or model. It is not a fixed notion, but rather a process of change in the relationships between social, economic, and natural systems and processes. A sustainability paradigm rejects the primacy of any one of these areas and seeks the opportunity for a shared view where quality of life for all the world's inhabitants (human and nonhuman) is not compromised by, or for, another. The vision of sustainable development emerged in the late 1980s and gained worldwide support with the publication of *Our Common Future* by the World Commission for Environment and Development (WCED) in 1987. The Commission defined sustainable development as development that meets the needs of the current generation without compromising the ability to meet the needs of future generations. This sentiment was carried forward at the Earth Summit in Rio de Janeiro in 1992, where over 170 countries adopted Agenda 21 and the Rio

declaration on Environment and Development. After many conferences and reviews on the potential to fulfill the goals of the declaration over a 10-year period, in 2002, the World Summit on Sustainable Development (WSSD) in Johannesburg created the platform to fully develop a paradigm of sustainable development at the highest political level. The Decade of Education for Sustainable Development (DESD 2005–2014) provided an international framework for cooperation and consolidation of education for sustainable development (ESD) across the globe.

The connection between the role of children and sustainability has been formally articulated in a number of global declarations and documents emerging from these types of intergovernmental summits and meetings throughout the past two decades. Historically, some of the most significant global documents and reports for stimulating discussions on children's role in the sustainability of the planet include *The Plan for Action* that resulted from the World Summit for Children and the Rio Declaration and action plan of *Agenda 21*. Both of these documents were endorsed at the Earth Summit held in Rio de Janeiro in 1992 and became landmark documents in the sustainability movement. The recent introduction by the United Nations of the 17 Sustainable Development Goals (UNDP 2015) is the stepping off point for new conversations on how the global and local communities in developed and developing nations, including children and youth, can plan and respond to the rise of global sustainability issues such as climate change and rapid urbanization while still maintaining equitable rights of the most vulnerable within our communities and the ecological sustainability of the planet. In the past, children and young people have often been seen as the recipients of development aid rather than the implementers. However, it is clear that the newly implemented SDGs are not something that any one stakeholder group can deliver alone – whether that be the government, the UN system, the civil society, or the private sector. An equity-driven approach has been identified as the means for empowering children and youth to apply the understandings of sustainability through the SDGs into positive

action for themselves, their families, their communities, and their environment.

Children and Education for Sustainable Development

ESD, like sustainability itself, is a dynamic concept with many dimensions and many interpretations. While some would argue that there is a need for a global definition and an educational plan of action, the experience of the Decade of Education for Sustainable Development illustrated that the unique cultural contexts of countries and their specific needs and aspirations meant ESD will always be interpreted and reinvented dynamically both at a global and local level. This means that often the language and naming of what counts as ESD, and its relationship to environmental education (EE), has been hotly debated.

In Australia, for example, the shift to ESD terminology has been somewhat slow and contentious. For that reason much of what is reported at a national level as ESD is also reported as Environmental Education (EE) or Education for Sustainability (EfS), interchangeably. While there are many overlaps in their purpose, ESD (and EfS) is much broader in its intent and curriculum scope than EE. Australia has adopted Education for Sustainability (EfS) rather than the UN terminology of ESD. At the beginning of the Decade of Education for Sustainable Development the Australian Government released the *Educating for a Sustainable Future framework*, where it defined the concept of ESD this way:

Environmental education for sustainability is a concept encompassing a vision of education that seeks to empower people of all ages to assume responsibility for creating a sustainable future. For many years environmental education has sought to develop knowledge about the environment and to establish an ethic of caring towards the natural world. It has also grown over time to recognise the need to engage with many different interests in society in order to address environmental issues. Environmental education for sustainability acknowledges what has always been true, 'that how people perceive and interact with their environment (their worldviews) cannot be separated from the society and the culture they live in'.

Importantly, recognition of the many values—natural and cultural—which the environment may encompass now frames the contemporary Australian understanding of the environment, including the protection of places of National Heritage Significance, based on their natural, cultural and Indigenous values. It is timely that this statement, *Educating for a Sustainable Future*, is released during the first year of the United Nations Decade of Education for Sustainable Development (2005–2014). (Australian Government 2006, p. 2)

While there is no definitive meaning of ESD, there are a number of key characteristics of what ESD supports as a program of education. ESD is transdisciplinary. “[T]ransdisciplinarity involves going between, across, and beyond different disciplines” (UNESCO 2004, p. 1). ESD is concerned with disciplines that improve our understanding of ecology but not to the detriment of engaging with studies of human culture, social sciences, geography, and the humanities. It emphasizes aspects of learning that enhance the transition to sustainability including future education, citizenship education, education for a culture of peace, gender equality and respect for human rights, health education, and population and sustainable consumption. It is about dealing with real world problems in real world settings (UNESCO 2004) with a focus on lifelong learning:

This concept of learning requires that education not only be as broad as life itself, but that it continues throughout the full span of life. Lifelong learning, including adult and community education, appropriate technical and vocational education, higher education and teacher education are all vital ingredients for capacity building for a sustainable future. ESD aims to empower everyone, young and old, to make decisions and act in culturally appropriate and locally relevant ways to redress the problems that threaten our common future. (UNESCO 2004, p. 2)

ESD also supports a pedagogy of inquiry that develops the skills needed for individual children and groups to engage successfully in a sustainable society, including critical and creative thinking; oral, written, graphic, and digital communication; collaboration and cooperation; conflict management; decision-making, problem-solving, and planning; using appropriate technology, media, and information communication technologies (ICTs); civic participation and action; and

evaluation and reflection (Malone 2009). There are a number of priority areas that need to be addressed in the global call for sustainable development. Teacher education has been a high priority in ESD since school teachers and other community educators are in a significant position to serve as agents of change in support of sustainability. Efforts have been made to develop international guidelines for reorienting teacher education; however, the frontiers between academic disciplines remain staunchly defended by professional bodies, resource allocation systems, career structures, and criteria for promotion and advancement. Experience of the last decade in majority world nations has also shown the usefulness of tailoring sustainable development to the needs of the poor, especially focused on women and girls. Investments in women's and girls' sustainability learning can translate directly into better nutrition for the whole family, better health care, declining fertility, poverty reduction, and better overall economic performance (UNICEF 2013). This adds up to the potential to make considerable on-the-ground actions for change.

Children and Sustainability Action

It has been argued that the erosion of children's freedoms both in their home life and in their schooling has limited children's capacity to expand their environmental literacy (Malone 2007; Malone and Tranter 2003) and their capacity to be active in sustainability issues. We know from research that independent experience in an environment increases environmental literacy, capabilities, and confidence. The more complex the environment becomes, the more capabilities are required, and the more it becomes an essential life skill (Malone 2004, 2009). Ironically, as the world becomes a more complex place and the sustainability issues we need to face as a global community become more extensive, the very life skills and relationships with others that we share this planet with are slowly being eroded.

Rickinson (2001, p. 220) in his review of literature on environmental and sustainability

education noted that although environmental information is easily accessible today by children from an early age in a variety of sources (mostly access to new technologies), "we seem to have produced a citizenry that is emotionally charged but woefully lacking in basic ecological knowledge" (Rickinson 2001, p. 220). Secondly, that the complexity of environmental issues and the demands for adults who will be able to deal with them "necessitates young people to be equipped with a fundamental knowledge of basic environmental concepts and processes" (Rickinson 2001, p. 220). And while young people do have considerable environmental knowledge and altruistic motives, because much of this "knowledge" is developed via media and not through direct experience or engagement in real world learning, "this knowledge is rather rigid and full of erroneous interpretation and models" (Rickinson 2001, p. 220).

Recently, Krasny and Tidball (2009) have been developing the concept of civic ecology as new spaces to consider the role of sustainability for children in urban settings. They believe that to support a growing urban environmental stewardship movement, there is a need to present a crossover between natural resource management and environmental education. According to Krasny and Tidball (2009), civic ecology's focus on active engagement with nature draws together "biophilia," "nature deficit disorder," and restorative environment theory. They argue: "...civic ecology poses questions about the role of stewardship practices *and* of environmental education programmes situated in these practices, in fostering desirable properties of social-ecological systems, including resilience or the capacity of a social-ecological system to buffer perturbances and to renew and reorganize in response to change" (Krasny and Tidball 2009, p. 467).

Nothing is more evident of this place-based sustainability focus growing in urban neighborhoods in western countries than the growing community garden movement. Community gardens integrate resource management, nature, health, and social and ecological values while providing often cross generational sustainability knowing

within the urban landscape. Educators who have also incorporated community gardening into formal sustainability programs recount that children who grow their own food are more likely to eat fresh fruits and vegetables, and when garden programs include discussions on nutrition and farming, children show greater knowledge about healthy eating, contrasts between urban and rural landscapes, and “big ideas” around biodiversity, sustainability, interdependence, and ecosystems. Due to an ongoing limiting of children’s experiences in their local neighborhood environments, school grounds and other green spaces in the city such as botanic gardens and community gardens have become one of the few places where children can interact with peers in a natural, outdoor setting with minimal adult control (Malone 2004, 2007; Malone and Tranter 2003) and have the types of encounters with the more than human world that could lead to child-initiated sustainability actions.

Conclusions

Children have a significant investment in sustainability, both in the present as activist in their own right and in the future as they come to inherit what adults have left behind. Whether composting their lunch scraps, recycling materials, cleaning up pollution, or counting the birds in the trees, sustainability for children is a mix of formal teaching in schools integrated with the experience of being and responding to the environment in their everyday lives. The introduction of smartphones, social media, and other ICT devices and programs has meant children now have the capacity to engage in children to children activist projects where schools and formal learning are no longer required. So while formal classrooms may have traditionally been viewed as location for children to exchange in sustainability, the learning environment where children engage in sustainability now incorporates all facets of a child’s life. Research around how ICT will impact on children’s role in sustainability in the future is still unsure as evidence is only just starting to be documented.

Over the past decades stimulated by global programs of action supported by campaigns and initiatives through the United Nations and other large NGOs, children through education for sustainability and in community sustainability programs throughout the world have been supported to take up roles in their local environment to consider how they can actively contribute to more sustainable ways of being with the other human and nonhuman entities they exist with on the planet. Whether we call it environmental education, education for sustainability, or just sustainability, supporting the capacity for children to situate “sustainability knowing” and “sustainability action” in authentic practices in their everyday lives is vital for the ongoing future of the planet. The age of the Anthropocene presents a number of pressing global issues; research evidence illustrates that continuing to support children’s role in addressing the challenges of sustainability will be an essential part of an ongoing process of environmental and social transformation.

Children's Participation

Christina Ergler

Department of Geography, University of Otago,
Dunedin, New Zealand

Introduction

In early 2015 three children walked to school on their own in Auckland, New Zealand. Tragically, they were hit by a car when they crossed a busy road. Officials quickly blamed the parents for the accident and lack of protection. One police officer, for example, commented that it is “unacceptable” for young children to walk to school without adult supervision. While the injuries are unquestionably heartbreaking for the children, their families, and the driver, the discourse around this tragic event – for whom is it “acceptable” to walk independently or on a more general level what are appropriate activities for children in different environments – reveals broader questions about children's place and their participation in society.

Children's status in society regulates their participation in societal matters. The dominant news coverage around this tragic accident viewed children as an object in need of care and protection based on the assumption that children lack the

capabilities to navigate the adult world of cars and traffic. The call to supervise children on their way to school then seems to align well with the picture of children as vulnerable individuals in need of safeguard. But how does the discussion change when children are viewed as subjects in their own right? When adults begin to ask questions around what children enjoy and value about walking to school? When adults ask them what should change in adult-dominated societies to enable children to walk to school safely and independent of adult supervision? How would children's participation in everyday life look if children's voice, their perceptions, needs, and desires were heard and included more widely? By asking these questions, the focus shifts from viewing children as objects to seeing children as subjects; children are viewed as valuable, active agents in shaping their lives and learning. In other words, this example highlights common tensions when discussing children's participation in society, the tension between seeing children as *beings* and children as *becomings*, and the tension between conceptualizing children as active, capable social agents or simply as future adults in need of protection (James and Prout 1997).

Children participate in everyday societal activities including political discussions, cultural events, and play activities and add to the social and economical well-being of their families and communities they live in. But to what extent and under what circumstances their participation is recognized, valued, or curtailed depends on how children's rights are enacted locally and through different institutions. This entry provides a brief overview about how children's participation is framed theoretically and practically in children's geographies. “Participation” is one of the terms researchers and practitioners frequently use but rarely engage with in any depth. Participation is an ambiguous term that can have many different meanings and connotations depending on context and circumstances. The term encompasses formal (e.g., political forums) and informal arenas of participation from family discussions about what to have for dinner to even children's active participation in research projects. Participation often carries the connotation of rights, empowerment, and

justice and describes various forms of social engagement. Hence, it is a concept that social studies of childhood scholars/children geographers can easily subscribe to for framing their studies or analyzing findings, but how participation is understood and enacted across the world varies. Although much has been written about “participation” in research and practice, participation remains a fuzzy concept that lacks a clear or unified definition and theoretical framing (Percy-Smith and Thomas 2010). This entry will work toward framing and theorizing participation as “meaningful participation.”

Why Should We Bother to Encourage Children's “Participation” in the First Place?

A common theme running through publications on children's participation is the lack of genuine opportunities and meaningful ways for children to “have a say” in matters affecting them both in research and practice. Children's silence in the coverage of the accident in the introduction to this entry is a prime example and aligns well with the common critique that children's participation in decision-making processes in their local communities or formal political arenas is absent or subject to adult scrutiny. A similar critique can be directed at the majority of research projects which still follow adult-set agendas and tasks. It is therefore not surprising to hear calls for researchers and professionals or local and governmental agencies to incorporate children's voices more explicitly in decision-making processes. As a first response, many formal participation arenas, such as youth councils or legal consultation processes (e.g., when parents divorce), have been established and many researchers follow the unquestioned moral obligation to use participatory methods in their research (Gallacher and Gallagher 2008). Participatory practices, outlined in numerous how-to guides (e.g., Driskell 2001), have the common aim of giving children opportunities to voice their experiences and perspectives on social and political matters. But what is the purpose of affording children these greater participation

rights and proving better arenas and avenues for participation?

Many reasons can be given why children's meaningful participation should be encouraged and fostered in all aspects of our society ranging from capacity building to safety and protection. This entry, focuses on rights, empowerment, and justice as this triad intersects the majority of domains in children's participation.

First, children have the right to participate. Participating in social and political matters is their right as citizens and a legal obligation outlined in the United Nations Convention on the Rights of the Child (UNCRC). Since the Convention was first ratified in 1989 by the majority of countries around the globe, a shift in thinking about children and their capabilities has emerged. The Convention refined children's status in society by putting forward their social, cultural, educational, health, economical, political, and civil rights and government responsibilities (UNICEF 1995). As a consequence, the research, sociocultural, and political arena has changed, and at least on paper, children's participatory rights have increased since the ratification of the Convention.

Second, meaningful participation empowers children and is a more democratic process. Including children as valuable members during the cycle of a research project or in policy development has positive effects for the participating child and the livability of communities on a local, national, and global scale. Incorporating children's ideas for change redirects the trajectory of research projects or policies. Outcomes are attuned to children's everyday and extraordinary experiences and their suggestions; for example, services to children, spaces for children, and children's places improve. When children's input for change is valued and addressed, they feel that they are being taken seriously. They do not only experience meaningful participation, and their self-esteem and confidence is enhanced, but they also gain practical skills along the way (e.g., speaking in public, voicing and structuring their opinion, learning about complex democratic processes). Children can then be considered by adults as active citizens and – not without critique – learn the necessary tool kits to navigate adult-driven

decision-making arenas and processes. Fostering flexible, meaningful, and realistic participatory processes in formal (e.g., councils, policy, learning) and informal everyday life settings (e.g., play) for children of all ages and abilities remains an unsolved task.

Third, it is just. Incorporating children of all ages and abilities as active citizens makes societies more equal and just. Moving beyond considering children's voice and acknowledging their agency as valuable change makers in everyday and political contexts divert existing adult-child relationships and power structures. Viewing participation then as a process of negotiation and co-learning, or in Freire's words "a dialogical encounter with people" (Freire 2001), changes the collaborations between ages, abilities, cultures, and ethnicities. It can link and improve adults and children's mundane everyday experiences and desires, their agendas, and their motives. To move beyond passive and tokenistic participation by children toward meaningful intergenerational and intercultural collaborations, children's participation should be genuine, realistic, and maybe even scaffolded to ensure a positive experience and minimize the burden for children (Ergler 2016). Existing power hierarchies and structures should not be reinforced during the process; true collaboration values the contribution of any party no matter how minimal or mundane it might be.

Evaluating and Measuring Children's Participation

Calls for key indicators are widespread to benchmark the realization, failures, and successes of children's affective and effective engagement in civic society and everyday life as individuals, groups, and citizens. To understand and shift the cultural climate in which children participate, the micro- and macro-contexts of children's participation in their everyday world (Bronfenbrenner 1979), is as important as the need to hold governments accountable for the successful and meaningful implementation of UNCRC. As such it is important to measure and evaluate the extent,

quality, and impact of children's participation on different levels. Impact in this context can mean influences on children themselves (e.g., confidence, capacities) on project, policy, and programme outcomes and on adults' (e.g., parents, professionals) attitudes toward children locally and globally. In other words, the aim is to address, benchmark, and support the realization of children's rights in all areas of their life.

An influential and widely used model to measure children's participation is Hart's ladder of participation from tokenism to citizenship (Hart 1997). Even more than 30 years after its first appearance in 1982, Hart's ladder remains an influential tool in assessing and negotiating children's participation in research and societal activities. The concept was originally developed to show the continuum of children sharing decisions affecting their life or the life of their community and was meant to foster democratic processes. Hart adapted Arnstein's (1969) model and categorized different possible modes of child-adult interactions in participatory practices.

The ladder consists of eight rungs with the first three "manipulation," "decoration," and "tokenism" representing different practices in which children's participation in different activities counters their rights. The remaining five rungs symbolize different degrees of children's active participation ranging from assigned roles in projects, but with informed roles, to activities initiated by children and less curtailed by adult scrutiny. Hart labeled these rungs as:

- Assigned and informed
- Consulted and informed
- Adult-initiated, shared decisions with children
- Child-initiated and directed
- Child-initiated, shared decision with adults

In a simplified version, Landsdown (2010) suggests classifying children's participation into three categories: consultative, collaborative, and child-led participation. Consulting children reveals their views and experiences leading to an improved understanding of children's lives, but where adults still manage knowledge and outcomes. Collaborative participation suggests a

partnership to engage in any stage of a decision, initiative, project, or service (e.g., involving children in medical, political, and educational decision-making processes). To achieve shared collaborations between children and adults, decision-making spaces need to become realistic and meaningful participation arenas for children. Child-led participation takes place when children can point out issues of concern and initiate and advocate change independently, but it remains questionable how realistic and meaningful such a form of participation is for children when adults act as a simple facilitator and children take on all responsibilities. Would child-led, collaborative participation processes speak more to children's capabilities, desires, and wishes than our current models and practices (Ergler 2016)?

Adults can have a clear vision how children's participation should look like and how they can meaningfully participate. While government agencies, nongovernmental organizations (NGOs), or researchers have developed particular projects and programme for children of different ages and abilities, they are important but not sufficient. These arenas often disguise inaction, political unwillingness for change, and children's empowerment can be limited to adult scrutiny. Implementation tends to be patchy and frequently tokenistic and varies in and between institutional settings, between sectors of government, and between different cultural and political contexts. Moreover, these child-appropriate spaces for voicing opinions are often not sustainable as they mainly engage the highest or lowest achievers in a society and usually only cater for a small number of children. Further they are dependent on the goodwill of adults. But what about very young children's or children with different abilities' rights? How can their voice be empowered meaningfully and taken into account? Expressing views is not enough, putting these views into meaningful actions is similarly important, but what does meaningful participation mean for different children?

Hart and Landsdown's participation categories have unfortunately mainly been interpreted as a linear process with the highest possible

participation outcome at the top. But they both emphasize meaningful, genuine, and authentic participation that requires a shift in adult's social attitudes and behaviours toward children as their priority (Hörschelmann and Van Blerk 2012). Children should be able to choose their level of engagement appropriate to their interest, time, and capabilities. However, in reality studies, programme, and policies tend to be judged only on whether they achieve the highest possible participation outcome set out by, for example, authors like Hart (1997). Too often children's involvement has been manipulative, decorative, or tokenistic to disguise the fact that children are dominantly passive participants.

Gallacher and Gallagher (2008) refer to child-led participation as "the tyranny of child-initiated participation." They warn about the dangers of moral policing that often occurs when researchers, practitioners, or planners are not able to get to this stage or include "child-led/child-initiated" participation as their aim for their research design, programme, or decision-making process. However, is the last rung of Hart's (1997) ladder of participation the one adults always need to strive for or a utopian adultist vision? Is it more meaningful for children to climb the ladder up and down or even jump off the ladder and determine participation in their own way? Maybe a more flexible, meaningful, and realistic model that is more attuned to children's desires, capabilities, interests, and manageability could finally effectively replace the ladder of participation and open up new discussions and theorizations about meaningful participation. However, no matter how a different model looks to evaluate meaningful participation (e.g., a jungle gym with many different forms and heights of rugs as an extension of Hart's model (Ergler 2016) or "realms" as alternatives to categorize participation (Francis and Lorenzo 2002)), children's ideas about evaluation processes and the necessary indicators should be married with adults' suggestions. Meaningful participation is transparent, relevant, enabling, inclusive, and respectful. To achieve meaningful participation, a reframing and retheorization of existing practices is required.

Reframing and Retheorizing Children's Participation

The most popular models of children's participation outlined above take children's integration as a starting point for theorizing participation in practice. This dominant focus on the operationalization of participation has been critiqued as it simply *integrates* children in existing societal structures rather than to change societal practices in order to foster *inclusion* (Percy-Smith and Malone 2001). However, not only is inclusion of children important but children's *meaningful inclusion*. Theorizing and conceptualizing participation in a more meaningful and realistic way requires critical engagement with at least three of the shortfalls present in existing operational models:

1. Overestimation of children's agency
2. Underestimation of the role of intergenerational relationships
3. Shortfalls in putting participation rights and values into theory and practice

Privileging children's agency without recognizing the relationships children form with parents, government officials, or even strangers in their neighborhood disregards the everyday realities of children's life. Putting too many expectations on children's capabilities to make decisions or even, as some do, to save the planet disrespects children's agency. Valuing them as actors in their own right also requires countering some of the recent movements, for example, in research design, of turning children into mini-clone adults without really listening to children's views on participation. Rather, valuing children's agency means to address the reciprocal and relational experiences of children's participation when interacting with younger and older peers or adults. It means to move beyond the moral obligation to work with children and begin to really advocate for change from a position of mutual respect. Theories of change, such as Bourdieu's (1990) theory of social practice or Honneth (2014) and Sen's (2000) conceptualization of freedoms and

entitlements, which are able to address the structural and agential limits of existing models and theories might be a first step in the right direction.

Conclusion

The aim of this entry has been to sketch out that participation is more than simply participating in formal and informal societal activities. Participation has to be seen in a wider context. How children's participation is conceptualised and what is valued about their participation has as much to say about children's role in society as it has about the structures and processes that frame children's abilities, capabilities, and rights to participate in their communities. Participatory processes cover a wide range of arenas of children's life from creating inclusive environments conducive for walking as suggested in the introduction to political arenas and democratic decision-making spaces outlined later in the text. Whether children's voices, needs, and desires are considered legitimate and promoted in their everyday life depends on the wider circumstances under which children are viewed in society. Children are active meaning makers and agents of change who participate every day in social activities transforming them and their social, cultural, and physical environments. Viewing children's participation in this way allows adults to rethink and reframe children's participation (even the arenas no one has yet thought of) and intergenerational and intercultural dialogues in more meaningful and creative ways. Rather than demanding "integration" of children, adults should rethink what meaningful and authentic participation as "inclusion" to accommodate children's experiences and values really means.

Children's Power Relations, Resistance, and Subject Positions

Marek Tesar

University of Auckland, Auckland, New Zealand

Introduction

Children are governed by hegemonic and resistant discourses in any ideological setting. While

children live in their ordinary, everyday life experiences, whether they are positive or negative, their lives demonstrate the complex nature of power relations in the ideological context of society. Two philosophers make strong contributions to discussions on power relations in early childhood: Foucault and Havel. In childhood studies, the work of both these theorists challenges the developmental ideas that are often associated with the singular child entity. Their engagement with complex power relations allows a reconceptualization of the child as a postmodern construct with multiple and fluid subject positions, that are temporally and locally produced within early childhood settings (Tesar 2015).

Who and What Is a Child?

This section introduces complexities and tensions inherent in biologizing childhoods and in the sociology of childhoods. Stainton-Rogers and Stainton-Rogers (1992) tell the fictional tale of a girl. The girl was named Nema, by a police-woman, after she was found by security staff in a department store, naked and all alone. Her naked childlike body barely wrapped up in a blanket, Nema could not remember who she was, or how she got there. She suffered from complete memory loss; the staff of the department store called the police and took her to the police station. There, Nema was examined by a doctor, and no visible inscriptions were found on her body. The doctor could only state that Nema's age was somewhere between 14 and 20. Nema's identity remained a mystery, and she was passive while being questioned. She struggled to answer any questions, due to her amnesia, and the police officer was helpless. Finally, the police admitted her to a local hospital: to have her body further examined. Within a week there was no abnormal behavior, apart from Nema's memory of her life now spanning only 7 days. Traditional science and disciplines, through the medical doctors and clinical psychologists, were unable to offer any solutions or help to Nema. Soon it becomes clear that Nema was in perfectly healthy shape and that there was nothing "wrong" with her body. But it was her

body that became the problem. Nema needed to have an identity; however, should it be the identity of a 14-year-old or a 20-year-old? The repercussions of such a decision are of course incredibly high: sexually, medically, legally, and educationally. Is the concern about the age of Nema's body? She seemed socially competent; however, should society let her be sexually active? Should Nema be allowed to vote, drive, or drink alcohol? Should she be allowed to see R16 or R18 movies? Should the innocence of Nema's childhood be protected, constructed, produced, and decided for her; or should her body be taken as the body of an adult woman, and the choice of what she wants to do with it be handed back to her?

The concern of what to do with Nema highlights the tensions between constructions of childhood as a biological stage or as constructed, assigned, imagined, and portrayed by society. A childhood studies lens shifts these concerns, by building on the argument that childhoods are socially constructed and invented and produced within certain governing rationalities. This focus differentiates childhood studies from psychological, biological, and developmental perspectives. Such biologizing, or staged, approaches to childhoods (Morss 1996) work to classify, segregate, place, divide, and distribute childhoods into sections and schooling institutions. Through this lens the absence of certainty about the biological age of a body leads to uncertainty in decision-making about what should happen with the child, how the child should be educated, and how he or she should grow up. By giving up knowing a child's age, we lose an ideal, an image of the good child, and also control over the child and decision-making on/for/with the child becomes a much more complex concern. This thinking is in line with what Prout (1999) calls the "radical disjunction between society and biology" (p. 3), where societal discursive practices lead to a view of the body as a cultural and social construction, rather than as a natural, discernable part of biological growth and development. An examination of power relations, ideology, resistance, and subject positions advances this speculative thinking.

Power Relations, Ideology, and Society

In Foucault's (1980) work, genealogies search for unexpected relationships and nonlinear, accidental origins, while they focus on complexities and contradictory productions of citizens and through a childhood studies lens, on childhoods, through power/knowledge relationships. Foucault's reinterpretation of Nietzsche's concept of a genealogy of morals allows childhood studies to analyze the power structures. Foucault's genealogy focuses on mundane, yet very complex, nonlinear origins of histories of the present. In childhood studies, furthermore, Foucault's thinking around the concept of governmentality is often utilized, as it allows considerations of macro political and economical apparatuses and at the same time close examinations of intricate micro relations and practices that allow subjects – in this lens children – to be producers in society and to research alternative, nonlinear ways of how political rationalities govern childhood subjectivities. It leads to examinations of how governments, systems, and societal agencies govern childhoods. Foucault's thinking guides the examination of techniques and instruments that are indispensable to the way government agencies operate. The traditional model of a juridical power construct claims that power belongs to a subject or that it can be possessed by a class, people or an institution, or adults, for example. Within this concept the subject or an institution at the top of the hierarchy possesses the power, which is subsequently pushed, forced, and distributed toward the bottom. Such a distribution of power is therefore punitive, dark, and repressive and usually takes the form of orders and pressure. Foucault (1991) argues that historically the way power was utilized was to punish and to discipline subjects' bodies. He rejects this traditional model of power of the individual and group and argues for a disciplinary type of power, where power is exercised and not possessed by any particular group or institution. Foucault's key argument is that power is not only repressive but also productive by nature, and his claim that power produces knowledge and subjectivities is decisive for childhood studies.

This productive nature of power means that power cannot be studied on its own. Power thus needs to be analyzed as linked to institutions, political contexts, ideologies, and the government, as the mechanisms of visibility and connections with the macrostructures. For Foucault, power is connected with knowledge, as power/knowledge, that emphasizes that as subjects are produced, so power is constituted through discursive practices and particularly through accepted forms of truth, science, and knowledge. In childhood studies, McNaughton (2005) examines the importance of power relations and troubles the truths about the notion of the child, thinking with Foucault to empower both childhood studies scholarship and activism and, as her scholarship demonstrates, for adults to question their practices, understandings, and claims about truths on the child and childhood.

Havel (1985) also analyzes the discursive difference between the public and private domains, as central to where he locates power. Similarly to Foucault's notion of disciplinary power, Havel's concern is with a shift in power relations in changing ideological contexts. For Havel, the way power operates in the public and private domain shifts. In other words, if subjects, including children, want to live a "comfortable" life without repercussions, they have to accept living within a "lie," which means to publicly conform with the system and its requirements. Children's private lives then can remain undisturbed by the governing system, as long as they do not cross into the public sphere. So for Havel, power relations are bound by a social contract that if children support the expected and prescribed rules and commitments of the classroom and society and publicly demonstrate their support of the governing regime, ideology, and the adults who are in charge of shaping it, children will not experience any repression toward them, and their private lives will remain untouched. In Havel's work, all subjects are subjected to complex and permanent forms of surveillance and self-surveillance. These mechanisms interact within an ideological context and its anonymous, selective and calculated power relations. For children, living in such a system thus encourages, and even forces, the

withdrawal from the public sphere into the private spaces of life.

These private spaces create "parallel polis," which provides alternative experiences for citizens. Benda (1991) applies this idea of parallel polis in various contexts including parallel education systems, childhoods, and discourses of knowledges. The parallel polis presents the resistant, private sphere of children's cultures and childhood undergrounds and is a significant concept as it recognizes life outside the public domain. It contributes to theorizing the tension between private and public discourses and their complex power relations. The notion of a parallel polis creates a possibility for small groups of subjects, such as children, to act upon events in radically different ways from other children in the public domain. In Havel's philosophy these complex power relations penetrate the whole society and shape the way children live, play, and learn. Within these power relations, the focus is not on how one social group uses power over the other group but rather on how the power relations produce the dynamics between these groups. As the possibility of a parallel polis demonstrates, it is also less about the directly oppressive nature of power but about power being harnessed and exploited to create spaces of resistance through subjugated knowledges. Havel, then, isolates ideology as an essential mechanism of power, as giving it a purpose, providing its identity, and connecting the power to the ideological rules and structures. Ideology is thus experienced by all subjects, including children, and is an irremovable influence on their everyday life. The notion of ideology, for Havel, is thus the binding element in power relations.

Havel's analyses of these complex power relations point out how all subjects have access to power. He does not reject the traditional, top-down model of power, as he notes how some groups of subjects – for example, adults and children – are considered to be powerful and others powerless. These minority groups can exploit the fluid and free nature of power that they harness and have access to. Havel's "power of the powerless" creates the possibility to exert pressure, to produce an anomaly in, and to resist

the governing structures and systems. While society and ideology may channel the hegemonic discourse within society and its institutions, where childhood subjectivities are formed and produced, the resistant discourse of a childhood underground is powerful and significant in the formation of childhoods and the ways children learn and play. Children are thus not passive in these complex power relations, but they are active agents and social actors and respond to the hegemonic dominant public domain. For Havel (1985), the ideological system in which children operate is an extremely multifaceted "network of manipulatory instruments" (p. 24) which is supported by a "precise, logical, structured, generally comprehensible, and, in essence, extremely flexible ideology" (p. 25) that responds to the scientific model of society. From the perspective of childhood studies, this is the challenge that children and young people experience when contesting the structural basis of society, when they are expressing their voice, agency, and power.

Children's Subject Positions and Resistance

Under these theoretical frameworks, children in the society publicly behave as is expected of them. In Havel's work, children are central to power relations as they live their mundane, ordinary childhoods. Every child is part of this system, even if they are on the fringes of the society and are often seen and portrayed by the traditional model of power, as powerless (Havel 1985). Thus, all children are both victims and pillars of the system and wider society; they struggle with and at the same time support the policies and requirements of their structural positioning within the society. The societal ideology ensures that the system operates in ways where the children do not necessarily believe in the system but share the narratives of following orders and acquiring political childhood subjectivities, as victims and supporters of the system. However, once outside of the gaze of the public educational institutions, ideology also enables children to abandon these

expected roles of victims and supporters (Tesar 2014).

Havel (1985) speaks of an "ideological excuse" (p. 29), a notion in which the ideology bridges the gap between the system and citizens. This notion underlies the way children behave, act, and live, no matter how false or true that reasoning is. Its essence is communicated throughout children's lives and continues to be a seminal part of their growing-up. Havel is concerned, then, with ideology as a "complex machinery of units, hierarchies, transmission belts, and indirect instruments of manipulation which ensure in countless ways the integrity of the regime, leaving nothing to chance. . ." and that it "...would be quite simply unthinkable without ideology acting as its all-embracing excuse and as the excuse for each of its parts" (p. 29). This ideological excuse explains the children's decision-making and positioning of being disciplined, of not being able to engage in their favorite play, and of not being able to fulfill their desires. In Havel's philosophy, all children use the ideological excuse and learn and exercise the appropriate ideologically charged knowledge. In other words, each child's personal domain is outside of the public sphere that demands that the child adopts certain discursive positions. These positions include the self-discipline to follow orders, to be ready to conform with other children, and to uphold the same ideals as others. Children however are social actors, who are capable of making decisions and challenging power structures through a simultaneous subject positioning as rebels.

The social contract between children and adults becomes the ritual, the automatism, which is the bridging element between the individual and the public structures of the system. When children accept and support the governing ideology, their actions become part of the power relations that are absorbed into the structures that constitute the system. The ideology, according to Havel (1985), becomes an indispensable, active, power component in the system: "[i]t is a principal instrument of ritual communication *within* the system of power" (p. 31, emphasis in original). So power is shaped by the relations between

children contributing to the system and the structure, where the ideology provides a "legitimacy and an inner coherence" (p. 32). The social contract within which children participate maintains the strength of the ideology through their everyday support. Havel claims that the ideology does not serve power but that power serves the ideology as "theory itself, ritual itself, ideology itself, makes decisions that affect people, and not the other way around" (p. 33). The ideology within the system is the binding substance that lets children exist in the public discourse without disturbance. This ideological substance needs to remain untouchable, undisturbed, and unchallenged, as the system depends on its ideology to be stable and publicly visible, and to continue to operate and fulfill its function of supporting the system.

Havel considers the system as a space where the lines of power are not linear, but cross-sectioned through all, including children, who, in their own way, are responsible not only for their decisions but also for the production of the public system. So the system and its ideology are not social orders imposed by an adult on a child but a system that has permeated all power relations between adults and children. This self-constituting dimension in the system is, as Havel (1985) notes, "impossible to grasp or define (for it is in the nature of the mere principle), but which is expressed by the entire society as an important feature of its life" (p. 34). Havel argues that there is a tendency in all human subjects to accept these conditions as subject positions of victims and supports, as well as to rebel against them. Havel argues that human subjects have a capacity to respond to this system and that children cannot be seen as pure victims of the circumstances of the system, as they actively and "freely" participate in the production of the public sphere and that the disrupting element of a rebel is present in each child. When children reject the rituals and rules, they may get labeled and otherwise punished, for challenging the everyday, mundane panorama of ideology, society, and power relations. In this Havelian framework, the system must react to all "cracks" in it and to the children that cause the crack, the disturbing rebels who have unsettled the system.

In Havel's thinking, the child rebels would not commit just an individual offense. By performing their rebel subject positions, they challenge and disturb the entire balance of power structures in society, performing their roles as social actors and their agency. They expose the system and shatter the power structures of the system and the ideology of the powerful and powerless that bind it. As Havel (1985) argues, everybody that

steps out of line *denies it in principle and threatens it in its entirety* . . . it is utterly unimportant how large a space this alternative occupies: its power does not consist in its physical attributes but in the light it casts on those pillars of the system and on its unstable foundations. (p. 40, emphasis in the original)

In a society, the boundaries between who is in power and who is not can be challenged and exposed by children. Boundaries of power can dissolve to the point where it is no longer clear who is in power and who is powerless. This thinking around power relations, ideology, resistance, and subject positions portrays a landscape in which children and their childhoods are subjected to the conditions that produce their subjectivities as both victims and supporters of the society and are interwoven as they demonstrate the complexities of its power relations and ideology. Children are active agents in this process as victim and supporter subjects and engage with knowledge and information that is outside of the public domain, for example, in childhood undergrounds, and at the same time act as rebel subjects. In a Havelian sense, children can thus be victims, supporters, and rebels at the very same time. Childhood subjectivities are produced within a system by what both Havel and Foucault would perhaps identify as technologies impacting on the self to produce the self.

Introduction

During the course of the twentieth century, children have come to be recognized globally as human beings with rights, which, when realized, provide them with a better quality of life, opportunities for healthy development, and the fulfillment of their potential. Rights are legally or morally justified entitlements to have or to obtain

something, or to act in a certain way. Children are defined here as people between birth and 18 years of age. The recognition that children have rights has had a transformative influence on how children are thought about and treated, not only by policy and lawmakers, but by professionals and other people who interact on an everyday basis with children. Respecting rights means that rights-holders are accorded dignity, while denial of rights threatens humanity and integrity. Rights arguments provide a reasoned and moral basis for reforms to practices and policies for children.

Historical Background

Swedish feminist and humanist, Ellen Key, published a book, *The Century of the Child* in 1900, which challenged the predominant vision of children as deserving of harsh discipline and control, and suggested an alternative vision of children as social beings with spontaneous natural interests that should be stimulated, the benefits of warm adult-child relationships, and recognition of the intrinsic goodness of children.

The turbulent history of the twentieth century, including two wars, when unprecedented violence, displacement, homelessness, and deprivation had a devastating impact on children, was the context for the emergence of concerns for children's rights. Eglantyne Jebb was a British pioneer of children's rights who had wide networks across the UK and Europe, and in 1919 established the Save the Children fund to ameliorate the plight of children. She advocated for the importance of rights for all children, regardless of sex, nationality, religion, or race. She drafted the first attempt to codify children's rights under the auspices of the League of Nations – the 1924 Geneva Declaration of the Rights of the Child. This was a brief one-page statement saying that mankind had an obligation to give to the child the best it had to give and that nations had a duty to relieve and provide material resources to children and to protect them from exploitation (Veerman 1992).

There were both individual and national champions of children's rights before, during, and after

the Second World War. Janusz Korczak (1878–1942) was a Polish pediatrician who had a profound impact on children's rights thinking, suggesting a principle of respect for the child, as opposed to nagging, scolding, and punishing the child. He fought for a more active, independent role for children and their comprehensive participation in democratic processes. Sweden, along with other Nordic countries like Norway and Finland, took a proactive stance toward children's rights and engaged in significant postwar efforts for children. Sweden was closely identified with the development of UNICEF, and with Radda Barna, a humanitarian organization closely affiliated with the Save the Children Fund.

In November 1959 the UN General Assembly adopted a revised and expanded version of the 1924 Declaration of the Rights of the Child. It asserted the child's right to special protection, to be among the first to receive help, to a name and nationality, to social security, free education, freedom from neglect and exploitation, and to the love of parents. These early declarations focused on the vulnerability and susceptibility to exploitation of children (welfare rights), and were less concerned with autonomy or citizenship rights.

The United Nations Convention on the Rights of the Child

In 1978 Poland proposed a convention on the rights of the child to the United Nations (UN) Commission on Human Rights, and subsequently in 1979, the UN declared an International Year of the Child. This was to be the beginning of 10 years of negotiation, which culminated in the unanimous adoption of the Convention on the Rights of the Child (the United Nations Convention on the Rights of the Child is generally referred to by the initials UNCRC, and this acronym is used in the rest of this entry) by the UN General Assembly in November 1989. A number of new and previously ignored issues were introduced to the debate about child rights during the drafting process, for example, issues of sexual exploitation, child labor, "street children," and children in prison. The UN Commission on

Human Rights brought together many national organizations, including a mixture of human rights organizations (such as Amnesty International) and nongovernment organizations (NGOs) that worked with children (such as Defense for Children International) to draft the treaty (Cantwell 2011). The collaboration between human rights organizations and NGOs greatly broadened the rights framework, making it very comprehensive, and reflecting a hard won consensus across the countries of the world.

The UNCRC (1989) contains 54 articles that range across three main categories of rights – provision, protection, and participation. Provision articles are concerned with children's rights to essential resources, such as education, healthcare, welfare, family life, recreation and play, and culture. Protection articles are concerned with protecting children against adversity, such as violence, abuse, discrimination, injustice, and conflict. Participation articles refer to children's civil and political rights, to a name and identity, to be consulted on matters that affect them, to be able to express opinions and take part in decisions, and to have access to information. Participation rights are an innovative part of the UNCRC, signaling a shift toward treating children like citizens and recognizing that they have human rights just as adults do.

The adoption of the UNCRC marked an important step forward in the implementation of children's rights, because conventions are considered "hard" law as opposed to declarations, which are deemed "soft" law. If countries ratify the UNCRC, this entails a formal obligation to meet its requirements, and States have to report periodically to the UN (at first after 2 years, and subsequently after 5), and receive feedback and recommendations (Concluding Observations) from the UN Committee on the Rights of the Child in Geneva. Currently 195 countries have ratified the UNCRC, including all members of the UN except South Sudan and the United States. States can ratify the UNCRC but apply reservations to particular articles. For example, the UK has a reservation opting out of rights for child migrants and asylum seekers, allowing them to be locked up for weeks or months before deportation.

There are four cardinal principles and major messages inherent in the UNCRC. The first principle is nondiscrimination and universalism: *all* children regardless of race, sex, language, religion, disability, or class are entitled to rights and should not be discriminated against (Article 2). Secondly, there is the principle of the best interests of the child being a primary consideration in all actions or decisions concerning children (Article 3). Thirdly, there is the principle of the right to survival and development (Article 6) and the right to be protected from threats to life (through abuse or conflict) and health (such as through disease). The fourth principle within the UNCRC is respect for the views of the child and an obligation to take the views of the child seriously (Article 12 and 13). Children who can form their own views freely should have these taken into account in accord with their age and maturity. Giving such prominence to children's engagement in society has been the most controversial aspect of the convention, because it challenges traditional constructions of children. It gives an alternative interpretation of children's interests, capacities, and status in society and has had a widespread impact on changing perceptions of children, from the passive objects of adults' actions toward seeing them as social actors and giving them space and support to take actions on their own behalf.

The UNCRC gives high priority to education, which was the topic of the first day of General Discussion, and General Comment Number One in 2001. Article 28 asserts the right of all children to free and compulsory primary education, and that secondary education should be accessible to all children. Article 29 says that education should be aimed at developing the child's personality, talents, and physical and mental abilities to their fullest potential. Education should be child-centered, child-friendly, and empowering and promote human rights, cultural identity, and respect for the environment. Although there was no specific mention of early childhood education in the original UNCRC document, the Committee on the Rights of the Child in its General Comment Number 7 (2006) made it clear that all of the rights in the UNCRC applied to young children (under 8 years of age) and that they are entitled to

participate in quality holistic early childhood education services that promote children's other rights, and that parents should be supported in loving and caring for their children.

Theoretical Background to Children's Rights

Childhood Studies (Initially Known as the Sociology of Childhood)

The paradigm of Childhood Studies, which takes an integrated multidisciplinary approach toward children and childhood, provides a conceptual foundation for children's rights. Childhood Studies emphasizes that childhood is socially constructed in multiple ways according to particular historical times, places, cultures, and child characteristics (such as age, gender, ethnicity). Constructions of childhood are embedded in discourses, which are ideas that are held together by a particular view of the world and imbued in language and local cultures. These persistent ideas about childhood (constructions) are seen as self-evident truths about what children can do, what should be expected of them, their value and position in society, and how they should be treated. For example, traditionally children have been marginalized, largely because they were considered to lack competence, rationality, independence, and experience. They were often treated as the passive objects of adults' socialization practices. Childhood Studies has questioned the hegemonic power of Developmental Psychology to shape our constructions of childhood, because within it children are viewed as on an inexorable pathway toward rationality, and childhood is assumed to be a relatively universal experience for all children. Instead Childhood Studies positions children as participating subjects, knowers, and social actors and as people who can make a difference through their actions (James and Prout 1997). There is an overlap between Children's Rights (especially participation rights) and Childhood Studies, since both propose that children have agency and construct their own social worlds, and that they are subjects not objects of control or concern. Another theme within

Childhood Studies is the diversity of childhood and the wide range of perspectives, knowledge, and experience that children bring. Children's experiences have to be studied within particular cultural contexts. Generalizations about children are hard to make because even children within the same family have difference experiences and views.

Sociocultural Theory

The essence of sociocultural theory is that children's participation and learning takes place in social contexts and that children gradually come to know and understand the world through shared activities and communications. Russian psychologist, Lev Vygotsky (1978) showed that children could perform more skillfully together with others and that social support and guidance helps them to acquire competence and independence. In the process of co-constructing meaning with adults (or peers) within close reciprocal relationships, children, initially spectators, become participants, grasp meanings, and become able to act independently and control their own behavior. The reason often given for not allowing children to participate is their lack of competence (often judged by age). The relevance of sociocultural theory for children's rights is that if children are provided with the support to help them understand problems and formulate their own views, they become much more able to take the initiative in solving problems and acting on their own and others' behalf. Sociocultural theory suggests that children's capacity to participate and take responsibility is highly dependent on the social and cultural context. If children have trusting and respectful relationships with adults, even very young children can communicate their intentions and views, and adults are likely to be more responsive to their voices. Sensitivity to and knowledge of children's current level of understanding allows for a gradual shift in the balance of power toward the child taking on more responsibility and control. It is therefore not a question of expecting children to be completely autonomous, but giving them opportunities and space to practice expressing their views, initiating action, and making decisions in partnership with others.

Children's Rights and Policy

There are many areas where children's rights advocates have been able to use the UNCRC to press for significant changes in policies and practices for children, and there are other areas where policies can be criticized because they do not comply with the UNCRC. Two areas where the UNCRC has had a significant positive effect on policy are presented in this section.

Physical Punishment

The Committee on the Rights of the Child (Paragraph 11, General Comment Number 8, 2006) defines physical punishment as any punishment where physical force is used to inflict pain or discomfort, however light. It is a direct assault on the rights of children and an invasion of their physical integrity. Physical punishment is the most common form of violence toward children and explicitly forbidden by Article 19 of the UNCRC, which says that children should be protected from all forms of physical or mental violence, injury or abuse, neglect, or negligent treatment through provision of appropriate measures (including legal). Progress toward the legal prohibition of physical punishment over the last 36 years has been rapid. Sweden was the first country to prohibit physical punishment in 1979, and it was a model of good practice. Not only did Swedish domestic law state that children had the right to care, security, and a good upbringing and should not be subject to corporal punishment, but the law change was accompanied by extensive measures of public education to ensure that people understood the reason for the change, as well as providing them with a comprehensive child and family welfare system to support parents in bringing up their children with positive discipline. Since 1979 progress has been fast, with 8 countries having achieved prohibition in 1999, 24 in 2007, and 46 in 2015 (at the time of writing), with a further 52 States having expressed commitment to full prohibition. Only four countries (Sweden, Finland, Norway, and Austria) had prohibited physical punishment before the adoption of the UNCRC, but since then a further 42 countries have done so. Legal prohibition has been shown

to be associated with less violent parenting and more negative attitudes toward physical punishment. Although the UNCRC was clearly not the only influence on the increasing number of prohibitions, it is hard to avoid concluding that it has been one major impetus toward reform. In its feedback to State parties on presentation of their Periodic Reports, the Committee on the Rights of the Child has been unequivocal in criticizing those States whose legislation provides a defense for some level of violence toward children (such as “reasonable chastisement” or “moderate correction”).

Family Law

Another issue that profoundly affects children's rights within their families is what happens when their parents separate or divorce. In the past children have often been the invisible and voiceless objects of their parents' actions or of legal proceedings. Their parents' separation may trigger a series of unwanted changes in children's lives, not just the separation from one parent, but moving house and school, losing friends, and having a lowered income. Children do have the right to stay in contact with both parents if they separate, according to Article 9 of the UNCRC. Children's participation rights (Articles 12 and 13), however, also affirm children's rights to information about their family situation, and to have an input and participate in decisions about their residence and contact. Even though children do not necessarily want to make a difficult choice about which parent they want to live with, they clearly value the opportunity to have a say and be informed. A rights perspective has had the effect of bringing about reforms to family law to better respect children's agency, voice, and participation. If parental disputes come to court, legal professionals have an important role in listening to children, explaining the legal processes, and helping them formulate views and wishes. But the statutory provisions of the law also have a significant impact on the realization of children's rights. In New Zealand the Care of Children Act 2004 recognized the importance of children's right to participate. Section “[Children's Rights and Policy](#)” says that children must be given

reasonable opportunities to express their views and that these must be taken into account in court proceedings. The New Zealand legislation is particularly progressive as it does not specify any age when children should be consulted, dispensing with any assumptions about children's competence to participate at different ages. There is an increasing commitments internationally to enhancing children's participation in family law decision-making, and a range of countries have modified their law to embed children's participation into decisions about families.

Citizenship, Inclusion, and Education

Dina Kiwan

American University of Beirut, Beirut, Lebanon

Introduction

The concept of “citizenship” is a highly contested one, one which has been contested throughout its intellectual history. These competing conceptualizations are based on different philosophical understandings of what it means to be a human being and the constructed relationship between individuals and the political community or State. Inherent in conceptualizing citizenship is the notion of exclusivity, with the various theories of citizenship defining who is included and who is excluded. The domain of education is typically considered to be one of the most fundamental sites reflecting the nature of society and the State, as well as being aspirational – striving toward a vision for the future of society. There is a long history of philosophers theorizing about the role of education in society, from the ancient Greek philosophers, Plato and Aristotle, to the twentieth-century American philosopher of education, John Dewey, and the twentieth-century Brazilian educator and philosopher, Paulo Freire. The contemporary nation-State sees education as a critical site through which to exercise its various policy aims including its authority, and so education is often a domain where policy aims are contested between the State, parents, community groups, teachers, and even children and young people themselves. In diverse societies, there are often debates regarding the educational rights of children from cultural, linguistic, or religious minorities. This entry provides a succinct overview of the intellectual history of citizenship, before exploring contemporary challenges with respect

to inclusion – covering age, disability, gender, sexuality, ethnicity, “race,” religion, and socioeconomic class. Different educational approaches and policies are reviewed in comparative perspective.

What Is “Citizenship?”: Theoretical Reflections

Typically, the concept of citizenship is traced back to the times of ancient Greece, approximately around the eighth century BC. However, it is important to note that the term “citizenship” is a highly contested term and has been contested throughout its intellectual history. In ancient Greece, citizenship denoted the relationship between a person and the city-State or “polis.” Before this, a person was defined primarily in terms of his social group or family. One of the earliest great contributions can be seen in Plato’s *Republic*, where the State was based on the idea of justice, and it was argued that there is a close relationship between the just society and just individuals. This conceptualization of citizenship was not like the modern legal conception of citizenship that we have today. Plato did not conceive of individual human beings actually possessing rights in opposition to the State. Rather he conceived of human beings as inherently social.

Aristotle, like Plato, also conceived of human beings – or, rather, men – as inherently political beings and that their nature could only be fulfilled by participating actively in the affairs of the “polis” (Heater 1990). So for Aristotle, he believed that the State served an ethical purpose. But these ancient conceptions of citizenship were very exclusive – they were seen as a privilege. Only certain categories of men were included, and so women, the very young, the old, those who did not own property, and those of certain occupations were excluded.

The Roman conception of citizenship, in contrast to Plato’s and Aristotle’s conceptions, was a more legalistic conception and one which was relatively more inclusive (Heater 1990). All free male inhabitants could be citizens. In addition, the idea of multiple citizenships at different

levels – the local as well as a more “regional” level (i.e., “Latin” and “Roman”) – was introduced. In addition, there was the idea of a sub-citizenship, where individuals were entitled to private but not public rights of citizenship (Heater 1990). The similarities between the Greek and Roman conceptions of citizenship relate to the emphasis on masculinity, warriorship, and owning property, which some academics argue continue to be the key axes of citizenship even today.

In the medieval times in Europe, the feudal system was a relationship between the landowners and those who worked for them. The workers gave their loyalty to the landowner, and in return they would receive protection. The loyalty was to a person rather than to a law or concept of nation, but some scholars conceive of this system as the predecessor to the idea of the citizen’s relationship with the State.

Modern liberal conceptions of the State and citizenship are typically seen as developing in seventeenth-century Europe. This was in the context of emerging ideas of the State and its sovereignty and the need to define allegiance and rights (Held 1993). This emphasis on individual rights is essentially a legal conception of citizenship. This tradition can be traced back to philosophers such as Hobbes and Locke. Hobbes emphasized the importance of the making of a “social contract” between individuals and the ruler or “sovereign,” and he believed that it was the responsibility of the sovereign to protect individuals. This emphasis on the individual is the modern element in Hobbes that has been carried through to contemporary times. According to Locke, he argued that human beings are “free and equal” because they have “natural rights”; this means they have rights just because they are human beings, with the potential of rationality. He also believed that the State’s role is to protect citizens’ rights, and so there is a need for a social contract. However, what is fundamentally different about Locke’s position is that the sovereignty remains with the people, rather than being a transfer of subjects’ rights to the State, as proposed by Hobbes; it is this conception that has laid the foundation for the development of liberalism, in that it prepared the way for popular representative government.

In contrast to liberal discourses that focus on individual rights and the relationship of the individual to the State, there is an extensive academic literature that critiques this conception. In eighteenth-century France, liberalism’s emphasis on reason as opposed to tradition was attractive, as at this time, French society was structured very much in terms of privilege, with the clergy owning one-fifth of the land in France, and people were very frustrated with this. In this context, the philosopher, Jean-Jacques Rousseau, argued for “participatory” democracy, and an active citizenry, an idea that subsequently had an influence on ideas during the French revolution and also on Marxism (Held 1993). While Hobbes and Locke argued for State laws to be minimal so as not to limit individuals’ natural rights, Rousseau believed that laws can enhance an individual’s liberty. He also believed that liberty and virtue are related, and human beings can only really be free and develop virtue in civil society (Rousseau 1968). Rousseau proposed that when human beings are in a “state of nature,” they are independent rather than free and, in this “state of nature,” are not moral beings. He argued that only moral beings can enjoy liberty.

So for Rousseau, human beings in a state of nature are inherently good, yet their potential is not fully developed. Once human beings enter civil society, this provides them with the environment to develop their capacity, and it is only in such a context that the notion of liberty can be utilized meaningfully and also, as a consequence, that we can talk of human beings as moral beings, whose humanity is realized through active participation in civil society.

Contemporary Challenges to Exclusive Conceptions of Citizenship

There have been a wide range of challenges to exclusive conceptions of citizenship – in terms of ethnicity, “race” and religion, gender and sexuality, disability, age, and social class, with some scholars questioning the usefulness of a concept that is inherently exclusive (Nash 2009). Historically, “ethnocultural” conceptions of citizenship

which define citizenship in terms of “blood” (“*jus sanguinis*”) are where the “nation” is seen to exist before the formation of the State. Germany is taken as a typical example of a country that understands itself in these terms. In this kind of conception, “citizenship” is constructed in cultural, ethnic, and religious terms, as opposed to legal terms, and this clearly has implications with regard to who can be included in this model as a citizen. In this kind of model, it is more difficult in theoretical terms to integrate “outsiders” as “citizens,” in contrast to the “civic republican” model, where inclusion into citizenship is understood in terms of committing to shared values and participating in the community (e.g., France). The Canadian philosopher, Will Kymlicka, is best associated with the theory of “multicultural citizenship,” which aims to accommodate ethnic and religious rights into a liberal model of citizenship (Kymlicka 1995).

Feminist critiques of citizenship started in the eighteenth century with challenges to the assumed lower status of women based on the idea that women were incapable of rational thought and therefore excluded from citizenship. This became a significant movement throughout the twentieth century with women campaigning for the right to vote. Although women in many parts of the world have achieved legal citizenship status, feminists argue that women continue to be second-class citizens even in Western democracies, given that the conception of citizenship is inherently patriarchal with masculine attributes – based on a public/private sphere distinction with women associated with the private, nonrational sphere, associated with property ownership, militarism, and employment (Pateman 1988). It has also been argued that citizenship is predicated on a normalization of heterosexuality and as such is exclusive in these terms (Richardson 1998).

Other conceptions in the academic literature include postnational or cosmopolitan theories of citizenship. In these models, it is argued that the nation-State no longer has the significance that it used to have and that citizenship is being transformed by international human rights discourses and legislation, as well as by the significant increases in mobility across national borders, as

witnessed by migration flows as well as refugee crises that challenge traditional ways of thinking about citizenship. There have also been challenges questioning the translatability and universality of the concept of citizenship outside of the Western liberal democratic context, with calls for decoupling “orientalism” and “citizenship,” whereby the West assumes that those living outside of the liberal West are incapable of constituting themselves politically (Isin 2005).

Different Educational Approaches

As noted in the introduction, education is a critical site for the nation-State through which to exercise its various policy aims. Citizenship policies through education illustrate States’ different conceptions of citizenship, including policy aims relating to inclusion. There are a range of approaches to citizenship education, which can be broadly categorized into four main categories – “moral,” “legal,” “participatory,” and “identity based”; these different approaches have different implications for the accommodation of diversity (Kiwan 2008).

Moral conceptions emphasizing the importance of having a “virtuous” character and being proud to fulfill one’s responsibilities are key features of these conceptions, which can be traced back to the philosophical influences of the ancient Greek philosophers, Plato and Aristotle. This can take the form of promoting certain values, which may be religious or secular values. Such terms as “character education,” “moral education,” and “education for common values” all reflect a vision of education whereby it plays a central role in ethically shaping the individual. This moral vision is typically presented as not only good for the individual but for society as a whole, often with policy rationales invoking education as important in tackling crime, lack of cohesion between communities, youth apathy, and so on. Often, public and policy discourses on promoting the importance of “shared values” view society as being in moral decline as a result of increased ethnic, religious, and other forms of diversity. The policy solution proposed in this model is presented in

terms of identifying and promoting a set of common values for society. Policy discourses that emphasize patriotism and loyalty to the State as centrally defining features of citizenship are examples of “moral” conceptions of citizenship. Some “communitarian” conceptions of citizenship – models of citizenship that emphasize participation in the community also – have this moral conception of citizenship; these conceptions have the idea that acting or participating in the community acts as a moral force bringing people together.

Legal conceptions of citizenship frame citizenship in terms of rights, influenced by modern liberal European conceptions of the State and citizenship developed in the seventeenth century. In models of citizenship education, this can take the form of emphasizing human rights and providing awareness-raising sessions to provide learners with knowledge about human rights. Some citizenship educators advocating models of citizenship education based on human rights frameworks argue that this promotes an inclusive conception of citizenship. They draw this conclusion as they make the assumption that because human rights approaches are based on a notion of universal or common humanity, this translates into an inclusivity with respect to citizenship rights. However, others argue that such approaches do not sufficiently acknowledge the institutional and often discriminatory structures through which such rights must be claimed and may in fact lead to even greater inequality in practice, through the creation of a number of sub-statuses (Nash 2009).

Participatory models of citizenship education are framed in terms of equipping learners with skills of active participation, an increasingly prominent approach to citizenship education in a number of contemporary education systems in Europe, the United States, Canada, and other parts of the world. Here, the pedagogy emphasizes learning through active engagement, developing critical skills of civic literacy, and through civic participation in community projects. Often, the concept of democracy is linked to such participatory approaches to citizenship education, whereby attempts are made to implement some democratic

practices within the school itself – for example, school councils. Intellectually, this kind of approach can be seen to draw on ancient Greek traditions, as well as, for example, the philosophy of John Stuart Mill, in the context of encouraging voluntary and community activity; he argued that active participation enables the development of informed citizens and was also committed to the notion of representative government (Mill 1983). While participatory models of citizenship are linked to democracy, it has been argued by some scholars that this does not necessarily support the accommodation of diversity as it can favor the majority, rather than allowing for hearing a variety of voices.

Finally, identity-based conceptions of citizenship education are those models that deal explicitly with diversity, identity, antiracism, multiculturalism, nationality, and global and regional aspects of citizenship. Some forms of citizenship education take the form of constructing a civic identity, with France taken as a typical example of this approach. Here, the national identity is framed as a civic identity, whereby ethnic and religious identity is prescribed to the private sphere. In contrast, multicultural citizenship approaches advocate the explicit recognition of diversity in the public sphere. There is a long tradition of a more cosmopolitan approach to citizenship, evident in many world religions, which have emerged in contemporary thought as a reaction to liberal and communitarian theories, due to a number of influences, such as globalization, increased migration, and conflict.

Conclusion

Educational Approaches

Approaches to citizenship education in Western liberal democracies tend to focus on participatory approaches, with an emphasis on participatory transformative pedagogies. For example, women’s peace activism has been characterized as a “dialogical” process that takes account of the differential subjectivities and positionings as well as sharing a commitment to the process. Giroux

(1991) has proposed the concept of “border pedagogy,” linking educational practices with a struggle for democracy. Border pedagogy addresses the relationship between knowledge and power and how it is represented to secure authority. By challenging such representations and discourses, it reveals the interests that are produced and legitimated by these discourses and practices. In addition, it is argued that through challenging borders, “borderlands” are created where the production of knowledge by learners and the marginalized rewrites their histories and identities, challenging universalist claims to knowledge. By promoting a dialogue between the past, the present, and the future, it opens up possibilities of optimism for locating oneself historically but struggling to act and transform public life. This notion is also captured in the concept of “transformative pedagogy,” with an emphasis on the development of the whole person, focusing on personal and social connectivity and transformation, self-reflexivity, and critical literacy, rather than the transmission of information. It recognizes that knowledge is partial and incomplete and socially constructed.

Linking Education and Inclusion

Increasingly, a range of diversities are explicitly recognized as central to conceptualizing citizenship in pluralist, multicultural societies of Western liberal democracies. Policy aims include equipping young people with critical literacy skills, combatting presumed youth apathy in society and toward politics, promoting social cohesion and shared values, and promoting ideals of the “good citizen” contributing to society. Citizenship education is also increasingly seen to be important for the nation-State in other parts of the world. For example, in the Arab world, citizenship education has been used to promote loyalty to the State through primarily didactic pedagogical approaches. With the changing sociopolitical context unfolding in this part of the world, there are interests in transformative pedagogical approaches to citizenship education, also reflected in international policy discourses, as exemplified by UNESCO’s 2015 international curriculum guiding framework for global citizenship education.

Cognitive Decolonization

Ali A. Abdi
University of British Columbia, Vancouver, BC,
Canada

Introduction

In his keynote addressed to the attendees at the Comparative and International Education Society (CIES) Conference in March 2015 in Washington, DC, the Egyptian economist Samir Amin, who is

well known for his scathing critiques of global capitalism and Eurocentric views of history, culture, and knowledge (see Amin 2010, 2013), presented a tableau of human capacities that refuses to assign more knowledge and achievement credits to any one group or region of the world. In Amin's reading of the situation, while there may be a tiny minority of what might be described as gifted (about four percent in the world in his estimate), and about the same number of intellectually challenged individuals, over 90% of all humans, irrespective of where they reside or their origin, have the same potentialities. Looking pragmatically at the history and current realities of humanity, especially with respect to how equal opportunities can yield equal results, it is not difficult to agree with Amin's observations.

In deploying Amin's analysis at the beginning of this piece, the main intention is to say that cognitive colonization is a hegemonic attempt that goes against such human realities. The issue is also attached to colonial assumptions of cognitive inferiority about non-European populations across the globe. As has argued (see Abdi 2008, 2012), the initial depiction of colonialism as mainly political and economic misses the important epistemological onslaught that was unleashed on the colonized's reading of their social and physical realities (Nyerere 1968; Rodney 1982; Mann 2006). In essence, therefore, to colonize people's physical and mental existentialities, one need not elevate the value of their learning systems, knowledge creation possibilities, and reflective capacities. That itself also goes against Amin's above observations as it applies a horizontal scheme of lower epistemic capacity to colonized populations.

From a critical reading of the situation, therefore, the problematic fabrication of uneducated colonized natives also contained, and was also intended, to influence the thinking of Europeans. To do so successfully, the continent's most important thinkers and philosophers were front and centre in spreading unsubstantiated negative depictions of non-Europeans with many people accepting these without evidence. After all, this was a time when the writings and opinions of Europe's most important philosophers were

hardly questioned, especially when these were deployed to shabbily concoct things about unknown peoples in what was faraway lands that did not have the privilege of challenging such assumptions in continental Europe. In essence, therefore, this was the beginning of comprehensive but certainly multidirectional cognitive colonizations that affected the thinking of many people in multiple locations of the globe.

European Colonialism and Early Constructions of Cognitive Colonization

With the early plans of European colonialism in full force and pragmatically driven by economic crisis at home (Luchembe 1995), one of the most important platforms to successfully undertake such massive project was to establish a two-front attack system that first attempted and, in real terms, succeeded in justifying to European populations the importance of what was termed the “civilizing mission” of primitive peoples. Here, the most important variables in the preceding sentence are “primitive peoples” which immediately represented a new “knowledge” construction about foreign contexts that actually were not known to the major perpetrators of this epistemic crime. From the eighteenth to nineteenth century and for colonizing Europe especially, the burden of descriptive verification seems to have been annulled with some of the most important thinkers including such so-called luminaries of Western thought systems and philosophies including but not at all limited to Immanuel Kant, G.W.F. Hegel, Thomas Hobbes, Jean-Marie Arouet (nom de plume, Voltaire), and Charles de Secondat (Montesquieu), who in their writings all attributed lack of civilization and nonhuman fulsomeness to non-European populations (Abdi 2008).

Interestingly, such bashing of extra-European contexts did not start with these philosophers. It actually preceded them by about two millennia where even within his limited geographical exposure, the classical Greek philosopher Aristotle was sure around 315 B.C. of the centrality of Europe to everything else that existed in the

world. That hubristic presumptive knowledge tradition was carried into the so-called Middle Ages, which in time-space realities were not middle times for everyone, by the Roman historian Pliny, The Elder, who in his book, *Historia Naturalis* (1496), attributed what he termed natural monstrosity to those who lived in Ethiopia and India. Indeed, the way these false ideas (masquerading as printed reliable knowledge) were fabricated was not apparently that difficult as neither fieldwork, nor verification, nor even visitation of the described places was needed. From there, one can clearly see the long line of false assumptions about the to-be-colonized since the fifteenth century. So the myths about others henceforward expounded and represented some of the first fragments of two important epistemic constructions that were necessary to establish the massive and multidirectional cognitive colonization and its main tributary of *otherizing* all non-European peoples from ancient times and into the twentieth century. The long-term and eventually tempo-spatially successful, cognitive and perforce construction of the other, i.e., those constructed as outside of European modernity, was important in establishing the world current. In this world, almost all habitualized into a categorized human valuation system where, in bitter realities, some are elevated and loved, while some are despised and disliked. But for the psychosomatically colonized, i.e., those who were depicted as inferior, and then physically colonized, the fateful story gets even worse. It was indeed such continuous worsening of the situation that slowly became one important trigger of the anti-colonial schemes of historico-cultural redemption struggle and attached possibilities of cognitive decolonization that were undertaken by the colonized for their physical and mental liberation.

Cognitive Colonization and Avant-Garde Cognitive Decolonization Thinkers

Concisely and perhaps in the most simplistic way, cognitive decolonization is about the colonization of the mind which may sound simple in its descriptive and condition-based representations.

What is more complicated though is to understand and analyze how the long history of mental colonization imprinted on the minds of the colonized could be reversed to achieve mental decolonization. So while one need not miss the complexity of the needed processes to reverse cognitive imperialism, as Marie Battiste (1998) contextually called it, it is still have to limit the space allocable to a long analysis of such complicated issue. To psychoculturally ascertain the realities of the situation, one can talk about the work of what is being termed here avant-garde thinkers of cognitive decolonization. Before those are discussed though, perhaps an introduction of the seminal work of another thinker who preceded them by about 600 years, the Tunisian historian and sociological philosopher Ibn Khaldun, will be useful. From his vantage point, Ibn Khaldun understood the power and breadth of mental colonization among conquered peoples. In his important work, *The Muqaddimah* (Prolegomena or Introduction) (2015 [1377]), he spoke about the horizontal mental de-patterning which afflicts the lives of the subordinated who over time, associate power, knowledge, and achievement with their dominators. De-patterning in that it effects the problematic and more often self-depreciating results of cognitive colonization that become manifest in the thought and behavioral process of the longue durée oppressed (Abdi 2009). As time goes by in these superior-subordinate relationships, noted Ibn Khaldun, the subordinated move from believing in the superiority of the victors to actually devaluing their own histories and cultures and begin imitating the ways and customs of the conqueror.

In cognitive decolonization perspectives, the findings of Ibn Khaldun were reaffirmed many centuries later by, inter alia, Albert Memmi (1991 [1957]), who lived in French-colonized Tunisia and observed how the colonized do not just eventually accept their inferioritized status but actually partake in the maintenance of the new status quo. A very interesting observation by Memmi, in this regard, concerns how those among the subordinated who do not see themselves at the bottom of the heap do everything to keep those below them down while accepting the

superiority of the colonizer. Memmi's work can be grouped into the cluster of avant-garde decolonization thinkers who should include, among others, Frantz Fanon (1967, 1968), Aimé Césaire (1972), Chinua Achebe (2000, 2009 [1958]), Julius Nyerere (1968), Ngugi wa Thiong'o (1986, 2009), Edward Said (1978, 1993), Marie Battiste (1998, 2013), Ashis Nandy (1997), Ranajit Guha (1998), and Walter Mignolo (2011) and whose critical works emerged as a result of European colonialism in Africa, in Asia, in settler-colonized North America, and to a lesser extent in Latin America. The lesser extent point on Latin America is that while most avant-garde thinkers, labeled here as such because of the unique temp-spatiality of their work (i.e., during the intensification of anti-colonial knowledge counter-attacks at the beginning of the second half of the twentieth century and later), most Latin American countries achieved their independence from Spanish and Portuguese rule either in the nineteenth century or close to the early parts of twentieth century. In addition, the elite that took power in postcolonial Latin America was not from the indigenous population but mostly from European groups that did not change a lot within the new political power structure.

While Memmi's work is seminal, perhaps the most important avant-garde cognitive decolonization thinker and philosopher is the Martinican-French psychiatrist and social theorist/philosopher, Frantz Fanon (1967, 1968). In his introduction to Fanon's *Black Skin, White Masks* 1986 edition, later published in *New Formations* (1987, No. 1), Homi Bhabha describes reading and remembering Fanon "as a process of intense discovery and disorientation. ... [as] putting together of the dismembered past to make sense of the trauma of the present" (p. 23). Fanon understood deeply and analyzed the history and consequences of ontological inferioritization through racialization and all the oppressive assumptions and practices constructed to sustain an unlimited platform of cognitive and related colonizations. In addition, he, perhaps more than any other critic of cognitive colonization and prospects for decolonization, explicated the situation so effectively in his two best known works, *Black skin, White*

Masks (1967) and *The Wretched of the Earth* (1968). For Fanon, the negative deconstruction of self via onto-existential inferioritization (Abdi 2014) reduces the colonized entity into other than what he or she was prior to the colonized-colonizer contact. The emphasis for Fanon here is more attuned toward critical and post-facto redoing of self and society after the totalizing and problematic colonial deconstructions and reconstructions.

Beyond Fanon and especially from the African vantage point of screening the situation, Achebe and wa Thiong'o should be two heavy weights in the annals of cultural, knowledge, and cognitive colonizations and decolonizations. The two effectively engage the subjective de-historicizations (i.e., their cultures, achievements, and beings all rendered ahistorical) and possible re-historicizations of their own learning and lived experiences. With both growing up in colonial Africa, Achebe (2000, 2009 [1958]) and wa Thiong'o (1986, 2009) experientially narrate the performative cognitive colonizations imposed on people which shifted not only their ontologies but also, and perhaps even more importantly, their epistemological locations. It is this combination of the many negative deconstructive schemes in the establishment of cognitive colonizations that must be also fully considered in the project of cognitive decolonization. Indeed, as Aimé Césaire noted in his excellent *Discourse on Colonialism* (1972), people's physical freedoms and willful actions will be potentially lost when their mental dispositions are so disturbed that they become something other than what they were in their precolonial times. That becoming of something else through forced cognitive realignments is also what Achebe in his classic, widely read work *Things Fall Apart* (2009 [1958]) so subjectively and intersubjectively brings to the fore. That brings up the issue of power relations and the centrality of epistemic valuations and devaluations that rationalize what was not, as both Fanon (1968) and Césaire (1972) note, rationalizable (i.e., not reducible to measurable and where necessary detachable space-time components of life) through the pretentious scientization of enlightenment's ideologies operationalized via modernity's

experiments performed on the psyches and bodies of the colonized.

To stay more with the psychological deformations that are stealthily formulated, one need never underestimate the colonial education systems that formed some of the most important components of the so-labeled civilizing mission. Being a subset of the overall deculturation of the colonized, as Edward Said (1993) so cogently noted, the arrival of colonial education was to push the project of cognitive colonization which was already sanctioned by leading European philosophers and partially enacted via the systemic deriding of almost everything that was African, Asian, or of pre-Columbus indigenous in what is known as the Americas. In speaking about the hidden power of colonial education, Hamidou Kane, in his excellent small book, *Ambiguous Adventure* (2012 [1963]), powerfully discussed the long-term effects of colonial education, where, especially for those who were educated in the colonizing metropolis, the primordial cultural discontinuities imprinted upon their psyche partially disjunctured them from their society and its needs.

With respect to Ngũgĩ wa Thiong'o (1986, 2009), he experienced firsthand the cultural and associated learning problems of colonial education in his native Kenya. As he noted (wa Thiong'o 1986), being exposed to deculturing and de-epistemologizing colonial education was tantamount to losing the center of one's world where even the linguistic repertoire needed to express about, and explain one's physical and social surroundings, was deliberately decommissioned from the context of the learner. For wa Thiong'o, the connection of the linguistic to the cultural is so central to any cognitive decolonization possibilities that reconstructing everything that was lost, irrespective of the educational and epistemic rehabilitation efforts needed to do so, becomes the sine qua non of cognitive decolonization. As he notes, the thick, horizontal cultural and linguistic decolonization needed can slowly serve as antidote for what he terms the realities of linguicide (2009) that have shifted the way people think about, relate to, and do their world. Indeed, to achieve cognitive

decolonization, especially for those populations that have experienced *longue durée* systems of imperialism, any cognitive decolonization prospects have to be informed by connecting the cultural to the linguistic and, by extension, both to the epistemic and attachable cognitive tributaries.

Selectively moving from the situation of Africa, and looking into the cognitive colonization structures and decolonization possibilities of the settler-dominated countries with continuously subjugated aboriginal populations such as Canada, the United States, Australia, and New Zealand, it should be important to realign the way such contexts are read. Focusing specifically on the cognitive decolonization work of some indigenous Canadian scholars, a brief look at the important analyses of Marie Battiste (1998, 2013), Taiaiake Alfred (2005), Willie Ermine (2007), and Glen Coulthard (2014), among others, should be important. While all of these have contributed to indigenous people's cognitive decolonization projects in Canada, perhaps it is good to start by highlighting the work of Marie Battiste who was the first indigenous Canadian to achieve full professor status in a Canadian university and her critically intervening work which was firstly effectively conveyed in her article "Enabling the Autumn Seed: Toward a Decolonized Approach to Aboriginal Knowledge, Language, and Education" (1998). In this writing, Battiste's point that without decolonizing aboriginal epistemic and epistemological realities, the project of cognitive colonization will not be dealt with effectively. In this writing, Battiste posits that without freeing the mind, you cannot free culture, learning, or social well-being. In her more recent work, *Decolonizing Education: Nourishing the Learning Spirit* (2013), Battiste takes the project of knowledge decolonization at least one step further, that is, from freeing thought processes to liberating actual programs of learning that should contribute to tangible spiritual and eventually to educational and community well-being.

More or less in line with the need to create counter-colonization spaces, Taiaiake Alfred (2005) suggests a unique intentional detour in achieving decolonized knowledges and life systems that refuse to stay with the trap of colonial

programming and oppression. He recommends critically reading and counter-hegemonically learning from the courage and strategies of those indigenous peoples who even in the midst of colonialism refused to be either physically destroyed or mentally de-patterned. He uses the reference of *Wasáse* which in the Mohawk tradition stood for traditional war dance ceremony and determined action. Then there is the issue of ethical space (the natural or contextually constructed interactive space between groups and individuals) to all human life and interactions that Willie Ermine (2007) talks about. In his terms, by being in the human family, important to continuously practice ethics in relation to others; as such, the quality of that ethical space whether it is inclusive and constructive or exclusive and potentially destructive can majorly determine the outcomes of what is achieved or not achieved with others or among ourselves. As such, cognitive decolonization requires a constructive ethical space that can capacitate the resurgence of suppressed knowledges and systems of knowing. Perhaps as a warning about the dangers of not doing it right in the new campaigns to reestablish liberating indigenous life systems, Glen Coulthard, in a book that is at least title-wise evocative of Fanon, *Red Skin, White Masks* (2014), reconsiders half-baked reconciliations that advance the rhetoric of recognition in the usual language of liberal ideologies that have not completely liberated indigenous peoples in Canada or elsewhere. In extending his analysis, he notes how the space for historical consciousness, cultural revival, and cognitive decolonization all have to be incorporated into any mechanisms that could reverse the depth and severity of cognitive imperialism.

Educating for Cognitive Decolonization

As noted above, cognitive colonization is the most enduring parcel of European colonialism as it spread into many parts of the world. Indeed, while the effects of physical colonization could be contextualized into the past, the same should not be said about cognitive colonization as its effects endure much longer. To just briefly stay

with the works of indigenous Canadian scholars referred to above, the effects of cultural and cognitive colonization are still present in the lives of many people who were exposed to the harsh situations of residential schools where aboriginal children were to be de-indigenized. Needless to add that such de-indigenizing of the platforms and outcomes of education are still being fully felt in tangible intergenerational terms that continue to perpetuate educational and mental colonization systems. But even such heavy labeling of the condition may not be enough to talk about the longevity of cognitive colonization which can affect, not just the children of those affected but very possibly, their grandchildren and many other generations beyond those. The same should be true in other parts of the world where, for instance, using the example of India, the fateful words of the colonial British governor, Thomas Macaulay (1995 [1930]), about the creation of an Indian class who were only Indian in skin color and blood but British in their tastes, dispositions, and worldviews, actually worked so well that such culture of cognitive colonization currently perpetuates itself. As Ashis Nandy (1997) noted, the power of mental colonization shifts the thinking of individuals in unique ways where, especially in the case of India, the cultural hegemony platform was as influential, if not more influential, than anything else that took place in colonial relations (Guha 1998).

It is with this understanding that the need to strategically think about possible ways of educating for mental decolonization is so important. Apropos that the initial forcers that created the situation in the first place, Eurocentricism and colonialism, now represented by neoliberal global capitalism, are still the dominant global political and economic systems in the world. Still, educational efforts have to be made and have been made in the cognitive decolonization sphere of which among the most prominent ones should be Julius Nyerere's (1968) *Ujamaa* (familyhood or village life in Swahili) project and its learning platform of "Education for self-reliance." Such education, as it was intended, should have counterweighed the

colonial destruction of African traditional education and social development systems. Alas, that was not to be effectualized as much as it was needed and was actually successfully repulsed by global capitalist forces. So the cognitive damage that has been done to the colonized is more or less still intact and actually perpetuated by current schooling systems which even, in so-called post-colonial contexts, is continuously towing the line of European learning structure and its Eurocentric knowledge categories that do not bode well for historico-cultural well-being and cognitive liberation. This is certainly where more critical work is needed to reverse the continuing effects of cognitive colonization and achieve cognitive decolonization. Without that, the now globalized projects of de-indigenization and epistemicide will continue (Santos 2014), and the gap between world have-nots and have-lots will continue widening.

Cognitive Imperialism

Marie Battiste

University of Saskatchewan, Saskatoon, Canada

Synonyms

Brain-washing; Cognitive assimilation; Cultural imperialism; Hierarchical invidious monoism; Hierarchical patrimonial monologue

Cognitive imperialism is a term that describes the mental, emotional, destructive, and traumatic effects of the experience of individuals and peoples forced to be educated and living under Eurocentric colonialism and imperialism (Fanon 1965, 1967; Memmi 1967, 2006). It is a form of cognitive manipulation used in social and education systems to disclaim other knowledge systems and values, known as a banking model (Freire 2004), cultural imperialism (Carnoy 1974), mental colonization or colonization of the mind (Chinweizu 1987; Hotep 2003), culturalism, cultural racism, epistemic violence, cultural genocide, or cognitive assimilation. However, cognitive imperialism's focus of the change is in the consciousness and knowledge systems, rather than in culture. It is integral to replacing one knowledge system with another knowledge system that results in various forms of nihilism, more than material, philosophical, or economic displacements attributed to political or cultural imperialism. It has had many lasting and subtle manifestations in various situations. Often those who perform cognitive imperialism are unaware of the nature of their action or the epistemic and other damaging consequences of their action. Indeed, most teachers believe they are helping the colonized, by providing them with better (i.e., informed, educated, superior, etc.) beliefs and patterns of action that improve their ability to accommodate or cope successfully with the colonial situation.

Cognitive imperialism (Battiste 1986) explores the lived experience among Indigenous peoples among others who have been forced into assimilation through their historical colonial experience with missionaries and various governments and their connections with schools, especially the federal government and the church Indian Residential School as revealed by the court order of the Truth and Reconciliation Commission of Canada. The Indian Residential School used compulsory education to kill the Indian in the child, the attempt to annihilate Indigenous knowledge systems and languages by fear, punishment, and hunger to assure compliance, thus disconnecting the child's self from the collective cultural and linguistic relationships within one's family, community, and knowledge system. Cognitive imperialism denies the child and their subsequent heirs to their heritage, knowledge, and language, to maintain the legitimacy of only one or colonial dominant knowledge system, one language, one culture, and one frame of reference – Eurocentrism.

Eurocentrism is founded within a particular constructed knowledge system created in the classics of European Greeks, Romans, and Christianity and other western European groups (actually there is no Europe, only a continent that is Asia), all of which has left some legacy of their learning, languages, and ideas. Eurocentrism is validated as a universal knowledge system and empowered through compulsory public education in the colonies and western world, which has been diffused to people at the periphery of Europe as a perceived gift of colonization. However, Eurocentrism has been the engine of cognitive imperialism. It has been the means by which whole nations and groups of people have been denied their knowledge systems, their cultural and spiritual identities, and their wealth confiscated.

Eurocentrism underlies all “Western” scholarship, opinion, and law (Blaut 1993). It is an ultra-theory of contemporary thought. It is not an opinion or attitude that can be altered by a multicultural or crosscultural training exercise. As an imaginative and institutional context, it is the dominant consciousness of contemporary lives, and all societies have been marinated in it or directly influenced by it. All educated peoples

are both the victim and beneficiaries of the Eurocentric educational systems that have taught us in the discourses of the ways of the conventional that have been prescribed as normative.

Eurocentrism provides the context for many academic disciplines and theories, which can be understood as integral parts of Eurocentric diffusionism. Eurocentric diffusionism in its classic form invents a world divided into the two categories. There is Greater Europe, which has a history, invents things, and progresses. And then there is non-Europe, which is thought to have no history, is stagnant and unchanging, and receives progressive innovations by diffusion from Europe. The theory of Eurocentric diffusionism postulates the superiority of European knowledge systems over non-Europeans knowledge systems. It asserts the distinction between these peoples lies in the superior quality of the European mind or spirit, which contains a certain intellectual or spiritual factor that leads to creativity, imagination, invention, innovation, rationality, and a sense of honor or ethics. The reason for the perceived non-Europe's non-progress is the lack of the perceived intellectual or spiritual factor that is inherent in the “European mind,” “European spirit,” or “Western man.”

Contradictions emerge in the cultural inclusions and add-on curriculum proposed to resolve cultural imperialism, the administrative resistances to or disinterest in changes in knowledge bases, knowledge keepers and holders, natural contexts for learning, and diverse demonstrations of success from education, holding firmly to scientific and culturalism in curriculum, training Aboriginal teachers in monocultural and Eurocentric contexts, diminishing the status and role of Aboriginal elders in schools, and grading quantitative practices. Affirmative action and equity of labour masks the systemic discrimination and practices of cultural imperialism, while elitist research and studies of indigenous education continue the discourse of knowing the Indigenous other, for in their uniquely different ways of being lay the answer to their marginalized and powerless position in society. This ideology is an exercise of cognitive power that seeks to change the consciousness of the non-European, not change the situation that oppressed them.

Derived from this empowered knowledge system of Eurocentrism, cognitive imperialism is constructed within non-European society as superior to other knowledge systems. It is the model of what it means to be educated, progressive, and civilized, and thus serves to legitimize its imposition as formal public education to be mandated throughout various stages of life and ages, regardless of its effects on other knowledge systems and the subsequent effect on individuals and collective psyche. Cognitive imperialism solidifies some groups with political power, and others are thus led to believe that they are lacking, inherently or naturally, because of their differences. It establishes the method and conditions to exploit, marginalize, or manipulate students and parents for the benefit of Eurocentrism, colonization, and imperialism, leaving a soul wound on the peoples (Duran and Duran 1995). Its benefits are imagined to enrich the economy of the colonizer States and the well-being of the colonized society.

Cognitive imperialism in compulsory education requires the generating of a set of beliefs in inferential, persuasive processes – a process that is cognitive in nature. Its basic constituent is the implicit acceptance by the colonized student of the superiority of Eurocentrism especially when it is compared or clashed with Indigenous knowledge. By this implicit acceptance, the student will usually tend to prefer Eurocentrism. In other words, cognitive imperialism is achieved when the colonized teacher or students adopts the epistemic principles of Eurocentrism. It is this acceptance that establishes a sort of implicit comprehension that in any matter involving cognitive abilities Indigenous knowledge system must be presumed to be inferior and irrelevant to Eurocentrism. It is important to recognize that cognitive imperialism is about the diminishment, devaluation, and marginalization of many knowledge systems of other diverse peoples around the earth, who find their knowledges, voices, experience, spiritualities, imaginations, and creativity marginalized, eroded, or erased.

Mandatory public education, supported by colonial governments, their elites, and supporting corporations, was justified and supported by monarchies, politicians, legislators, States, courts,

social systems, policing and other regulatory provisions through other forms and strategies, including official languages, normalized discourses, public and often social media, publishing companies, academic books, curricula and training of teachers, as well as of other professions, including commerce and legal education, humanities, and sciences. Though the prismatic structures of knowledge and power, cognitive imperial empowers epistemic authority into social authority to support power structures capable, by a variety of means, to ensure its enforcement. These means range from appealing to overt and covert forms of discrimination, making use of socioeconomic rewarding or punishment, establishing exclusive standards and rules of conduct, and sheer violent coercion. Over time, these means having gone through diverse iterations and changes; however, the focus on compulsory education and assimilation of the children through cognitive imperialism has lasted through at least four centuries and multiple generations. The art of cognitive imperialism in education has not always been successful, however, with the decolonization movement of Indigenous people arising over the last century as characterized by refusal, rejection, and resistance to Eurocentrism and its authority and to restoring and revaluing Indigenous knowledge systems in liberation and emancipatory struggles (Hoppers 2002; Hoppers and Richards 2012).

Despite the fact all peoples are born into languages and knowledge systems, the transformation of Eurocentrism into a cognitive power base has been built on controlling the meanings and diffusion of knowledge through schooling, scholarship, publishing companies, government standards, media, and economic privileging. It has become an ideology that has contributed to the oppression of diverse knowledges, an ideology that determines what counts as knowledge in schools and universities and which knowledge is rewarded with mass diffusion, grants, scholarships, economic or professional prestige, or other forms of research funding. It has negated the alternative processes for other knowledge systems to be acknowledged as processes of inquiry to explore new solutions and new ideologies of

being in the world. Using one knowledge system to be both the diagnosis and the solution is a form of culturalism (McConaghy 2002) that is also informed by assumptions of superiority and by historical conditions of naturalism, colonial desire, patriarchy, discourses of nationalism, and the rise of globalization. Culturalism is a form of knowing that provides both lens of analyses and filters of solutions.

Compulsory education can either maintain domination or it can liberate (Minnich 1990). Every school is either a site of reproduction or a site of change, and every administrator and teacher has a choice to make about the future of society. My awareness that the educational process in Canada supports cognitive imperialism has led me to seek a decolonized Aboriginal education. My search has been an inspiring part of my own self-education and growth. Postcolonial and Indigenous scholars and researchers have made me aware of the conditions that support colonial policy and how we, as educators, have unwittingly sustained the power of Eurocentrism. My search has also made me aware how important it is to understand the colonial foundations of the Eurocentric diffusion of knowledge in Canadian institutions and made me aware that it is not enough to change the content of curricula or the language of instruction used in schools. A personal commitment on the part of educators to unpack and understand their own positionality and location in relation to oppression and to the oppressed is required as well through an explicit critical examination of privilege, dominance, and normalized discourses of the other. Each and every one of us has a responsibility to contribute to the decolonization of education.

Today, learning and the control of education in exclusive Eurocentric or Anglocentric knowledge societies have gone hand in hand with serious inequality, exclusion, and conflict exemplified in aborted achievements among Indigenous peoples in schools, lack of self-esteem, fragmented identities and self-awareness, and underdeveloped capacities. The European settler societies that have developed the current conventional systems have disregarded, minimized, or fragmented Indigenous knowledges and their pedagogies

and teachings as core epistemologies. Through hegemony and power over relationships, the controlling elites have inferred their own privileges as signs of their superiority, respect, and integrity, while treating Indigenous peoples' poverty, lack of fluency with colonial languages, reserve living with all its patriarchal dysfunctions as a normal part of their existence as opposed to the situations and historical legacy of cognitive and cultural imperialism and colonialism which they created. Disrespect for Indigenous epistemologies and theft of knowledge and its products have alienated Indigenous learners from formal learning and Indigenous peoples from colonial research foundations, contributing to a legacy of mistrust between institutions of higher learning and Indigenous peoples, their governance bodies, and their institutions of learning.

More importantly for many Indigenous researchers is the awareness that little is known about the Indigenous knowledges and teachings that have the potential for arresting the colonial damage and ways to deal with the tragic legacy of our histories. Silence, says Elizabeth Minnich (1990), is the shield of domination. Silence to the true histories of Indigenous peoples with European settlement, to their treaties whereby their lands were taken, and to the stolen languages and stolen childhoods of the Indian Residential Schools are all of products of cognitive imperialism.

Perhaps it is too easy to point to the enduring examples of the destructive effects of colonization and cognitive imperialism. It is more difficult to understand the processes and methodologies of decolonization and how to blend together distinct and different knowledge system, which is the current task of Indigenous and non-Indigenous educators. Conscientization means becoming aware of the existing hegemonies and practices that entrench the Eurocentric social, economic, gender, cultural, and political privileges that destroy Indigenous peoples' center within their own cultural context. This requires developing a critical consciousness that activates questions and concerns about inequalities in society and that interrogates the cultural and structural outcomes of inequality and structural racism evident in public services such as education, health, and justice.

Transformative action in decolonization of cognitive imperialism means action that is both reflective and reflexive with respect to theory and practice (Smith 1999, p. 38). Rather than merely developing a critique of what has gone wrong, transformative action creates meaningful change by intervening and making a difference in everything Indigenous people do and at every site of struggle they take on. Transformative action is about thinking and reflecting and entering into dialogues with one another about work and about the struggle to decolonize. In the area of education, it is about reflecting on what the role of schooling has been, what barriers have excluded some voices from participation in schools, and what perceptions others hold that prevent them from fully benefiting from what schools can offer.

It is clear to many educators that the attempt to decolonize and actively resist colonial paradigms is a complex and daunting task. The colonial educational model offers a fragmented and distorted picture of Indigenous peoples. Understanding Eurocentric assumptions of superiority within a historical context and the continued dominance of this mode of thinking in all forms of contemporary knowledge is foundational to change. In addition, Indigenous people need to renew and reconstruct the principles underlying their own worldviews, environments, languages, and forms of communication. They need to understand how all these elements interact to construct their humanity.

Most Indigenous peoples around the world continue to suffer trauma and stress from genocide, and their lives continue to be destroyed by colonization. The work of educators, both Aboriginal and non-Aboriginal, is to heal the lasting effects of cognitive imperialism and enable the human potential of all peoples. Indigenous peoples are not just part of the dialogue. They need to advance their own postcolonial discourse about knowledge systems. This discourse must interrogate current thinking, curricula, and structures from both Eurocentric and Indigenous knowledge system. It must question who benefits from them and how. And it must work actively to transform cognitive imperialism by respecting Indigenous knowledge and ways of thinking and by helping

others, especially Indigenous students, to understand the roles they must play in effecting change. The efforts of educators need to reveal inconsistencies, challenge assumptions, and expose ills of any knowledge system. Educators need to search within themselves for meaningful principles of knowledge systems that will guide all children to lead dignified, respectful lives. Sometimes this will require patience with those who have internalized cognitive imperialism that demeans Indigenous culture and language, and that leads Indigenous people to destroy themselves. Indigenous knowledge can be a source of healing, inspiration, creativity, and opportunity. It can contribute to equality, solidarity, and tolerance in the world. Respect for Indigenous knowledge begins when Indigenous people provide the standards and protections that center this knowledge.

The final report of the Royal Commission on Aboriginal Peoples, the Truth and reconciliation Commission (TRC), and the global consensus of the United Nation Declaration on the Rights of Indigenous peoples and a host of other Indigenous researchers and postcolonial scholars and leaders have made it clear that Indigenous peoples see education as the hope for their future, and they are determined to see education fulfill its promise (RCAP 1996, Vol. 3, pp. 433–434). No longer can institutions excuse their reluctance to change by saying that they do not know what Indigenous people want (Havemann 1999, p. 70). The Canadian Constitution articulates the principles of respect for Aboriginal rights and treaties. It is important for educators to be aware of this. This new constitutional framework enables educators to include Aboriginal knowledge and heritage in every curriculum and educational structure.

Collective Praxis: A Theoretical Vision

Luis Mirón

Loyola University New Orleans, New Orleans, LA, USA

Introduction

Over previous decades, cultural studies in education has begun to take seriously the idea that the political and cultural spheres maintain their own sectors separate from the economy. Agency not only is a theoretical possibility; it has become a conceptual assumption. In contemporary terms (see McCarthy 2016), the everyday artistic performances “ordinary” human beings engage in matter and performative discourses have material effects.

Following Nicos Poulantza’s (1969, 1978) work on the relative autonomy of the State, the site of schooling should not be considered a mere epiphenomenon. Rather, as both a political institution and a sector in the cultural sphere, the school is inexorably a site of cultural and ethical/moral politics. The global processes of neoliberalism and the undermining of the public square in education differentially affect public schools and their ever-shifting student bodies. Students feel simultaneously trapped in a series of never ending high-stakes testing and envision, along with their parents, “opting out” of regulatory renditions connected to recent policy frameworks such as the Common Core State Standards. This theoretical trajectory traced above renders possible political movements in the new spaces of the public school and the public square more broadly (Smith 1992). The implications for everyday cultural production and counter hegemonic social movements are, therefore, profound.

After decades of work, this remains an emerging field of study. The authors in this emerging field can be understood as writing in the generative tradition (Freire 2000a). Authors such as Cameron McCarthy (2016) and Maxine Greene (1995) are prominent. They foreground active resistance, agency, cultural and social production,

creativity, and grassroots political revolution on the grounds of everyday experience. In situating the future of cultural studies in what Freire (2000b) first described as generative discourses, it is necessary to highlight the potential freedom of agency generally and collective praxis specifically, leading to a radicalization of the institution of democracy and democratic practices as embodied in the *Occupy Wall Street* and *Black Lives Matter* movements. In consequence, scholars must heed the moral imperative to engage in the practices of countering inequalities through collective praxis.

Prior to the theoretical transformation outlined above, the theoretical assumptions in the vast field of cultural studies in education were such that structure mattered and it was given primacy in analysis. That is to say that social structure generally, and cultural norms and practices in particular, superseded human agency, be it individual or collective. The latter was often referred to as political agency.

One significant example of this can be found in the writings of neo-Marxists in the 1980s and 1990s, which placed lived, cultural experiences in the background. Here, it is important to *foreground* everyday cultural and social practices as these relate to the notion of collective praxis. A problem with previous scholarly traditions in cultural studies relying on neo-Marxism is that they do not go far enough. A perceived flaw with this theoretical traditional (see Mirón 1996) is that it all too often characterizes resistance as a rather happenstance kind of cultural epiphenomenon that, on the surface at least, appears accidental and occasionally presents actively resistant students as cultural outliers. This foundational work on the cultural politics of schools, however, serves to foreground and inform current work as well as the critical pragmatic notion of collective praxis (Maxey 1991).

Theoretical Roots of Praxis in Cultural Studies

Defined simply, *praxis* within the field of critical pedagogy and cultural studies refers to a

micropolitics of schooling grounded in macro-level social theory. It is an intersection of theoretical reflection and culturally situated agency (Kirylo 2011). It is the core idea that without theory, action is virtually meaning-less. If not altogether useless, of no practical consequence, action without theory/reflection is *undisciplined* improvisation. Taking impulsive action without a theory of social change is to move too fast toward solutions, rather than the more deliberative approach, problem posing (Freire 2000a; Kirylo 2011). These all too often result in unintended consequences that do not provide sustained solutions to complex problems.

Arguably, the field of cultural studies took a radical evolutionary turn in the late 90s and early twenty-first century when it embraced the notion of “cultural production.” This development was perhaps aided by the tradition of resistance studies, which relied on rich ethnographic data to establish that students need not succumb to the predetermined impulses and arcs of history. Simply understood, students could actively participate in cultural production as both antidote and transformative agents in opposition to the oppressive social structures and their properties of social reproduction. Moreover, one need not become a disciple of Paulo Freire (2000b) to realize that students could overcome their class limitations and abstract structures that seemed to forever relegate them to lives of oppression. Praxis – or, as others outside of cultural studies in education have characterized it, “reflection in action” – could transform their lives individually and, more importantly, collectively.

A Theoretic Riff on Praxis

Building on the originating tenets sketched above, three interrelated theoretical themes in the trajectory of cultural studies are important to understand for the state of the field today. These themes are: struggle, empowerment, and collective praxis. The third theme is a kind of amalgamation of somewhat dated concepts in radical scholarship in the field – the practice of and the need for social action.

Struggle

Beyond the notion of cultural politics, struggle refers to the endemic social conflict embedded in the compulsive drive within organizations to control their workers – be they relatively well-off academics or low-wage service employees in public schools. Despite its leanings toward everyday lived experience, work in the field of cultural studies of education has tended, for the most part, to focus on the macro level, that is, meta-theorizing and abstract concepts such as cultural production. The notable exceptions are the ethnographic studies that have looked closely and deeply, both at the K-12 and higher education levels – at what practitioners and students actually say and do. Complexly layered examinations of voice, discourse, and teacher and leader performance in educational institutions serve as a few examples of this work. This work has largely not been associated with the neo-Marxists' discourses of struggle against global capitalism. Although perhaps an overgeneralization, the resistance studies literature has tended to highlight the dominant impulses of capitalism. Paradoxically, much of these arguments at once consciously aimed at undoing the subordination of the working class while also positing totalizing narratives that allowed little room for individual transformation. Contrasting with the idea of praxis laid out above, struggle should be conceived of affirmatively, as potentially realizing societal transformation through collective praxis. Although this distinction may appear to not have material significance, language – especially theoretical nuance – matters.

These kinds of struggles are therefore human, existential conflicts over values, specifically moral-ethical dilemmas and choices over philosophical questions – what is right and who should benefit from education. These questions cross over into the study of moral-ethical leadership (Maxcy 1991) in the fields of leadership studies and theory. These struggles are also inherently political in that they are situated in bouts over power, although it is often clear that subordinate groups such as students and members of university academic departments are frequently powerless. Typical studies of the cultural politics of

education tend to focus upon political struggles against the capitalist system writ large. Approaches that give theoretical value to personal narratives (stories), though underrepresented in this literature, are also important. In this sense the battle is, on the one hand, hopelessly lost because the overarching system, be it economic or regulatory (bureaucratic), “always wins.” On the other hand, these narratives can evolve into tales of a struggle for hope. This transformation leads, naturally, to the concept of empowerment.

Community Empowerment

From this understanding of struggle, the concept of community empowerment can be understood to be contradictory. At the center of this understanding, however, is the drive to enable oppressed individuals and communities to develop power and the capacity for social change (Mirón and Elliot 1994). The ends of community empowerment are often concomitant with efforts to bolster the common good. Approaching the concept of empowerment through the lens of Foucault, mechanisms of social control simultaneously function to limit individual empowerment but open up the discursive spaces to shift understandings of social change.

Inherent in the concept of community empowerment is the characteristic of inclusivity, which connects individuals to the pursuit of the common good. From the level of the individual to the global scale of twenty-first-century economic and social relationships, the concept of community empowerment entails the unity of different individuals and social groups in the pursuit of altering the dynamics of power. How these processes play out connect to the third central concept: praxis.

Collective Praxis

For some, notably Paulo Freire, praxis connotes an inherently collective enterprise. The notion of generative themes alluded to above implies groups of actors coalescing around posing common problems situated in everyday experiences. Following Freire (2000a, b), collective praxis can be conceptualized along two dimensions. The first is as a shared knowledge and conscious awareness

of “reading the world and the word” (see Kirylo [in press](#)). The second dimension entails the practical social action aimed at the ultimate transformation of not only situated oppression, but also cultural revolution – bringing a degree of parity among unequal relations of power.

Historical examples of the latter are the inclusion of indigenous populations in the Guatemalan national assembly and the preservation of indigenous languages and culture among the Guaraní in Paraguay (Kirylo [2016](#)). In both of these examples from Latin America, native populations have overcome centuries of oppression and political subordination to gain inclusivity in each country’s cultural and political institutions. In the case of the Maya in Guatemala, they were elected to national public office; in the Guaraní case, their native language was placed on a cultural par with Spanish.

Collective praxis is a kind of politically conscious gestalt, which brings the personal awareness that the historical and contextual conditions that led to oppressed circumstances need not stop with the individual. Indeed, personal awareness is merely the starting point for a shared theoretical understanding of the conditions that wrought, among other forms of oppression, poverty, racism, the exploitation of women, and homophobia. It goes without saying that systemic disenfranchisement is not something experienced solely by individuals in isolation. By definition, this understanding of systemic suffering is *holistic*, meaning it affects entire populations of people, local communities, and in some cases, large swaths of cities, for example, Detroit and New Orleans. One data point is sufficient to drive home the fact that these forms of systemic oppression are experienced collectively, the unemployment rates in urban centers such as New Orleans whose rate among African American males exceeds 50%. This form of collective experience of oppression precisely opens space for the ultimate transformation of oppression through praxis.

Affirmatively stated, both individualized and a holistic understanding among communities of systemic oppression morally necessitates an enlightened action to change the world. This

can be understood as a global critical pedagogy that originates from a deep understanding – a theory of social circumstances including poverty, sexism, and racism – and culminates in an intense emotional revolt against a sometimes-nameless enemy, while at the same time embracing a deep, compassionate love for the downtrodden. From this understanding, it is necessary to move beyond militaristic armor to cultural weapons comprised of a sophisticated knowledge of what in a social context often involves socially constructed structures, political institutions, and social practices that embrace putative scientific conclusions.

In summary, the discussion above has sought to trace a specific theoretical and empirical literature – cultural studies in education – linking it under a broad conceptual framework that can be understood as collective praxis. Admittedly, situating this literature within a broad intellectual tent is fraught with difficulties, not the least of which are embedded contradiction and critiques of my own critiques of neo-Marxist normative biases and metanarratives which all too often have tended to dismiss the significance of marginality and subaltern subjects on the questionable assumptions that these subjects are enveloped by global capitalism. What follows below are some possible impediments to the potentially overly optimistic theoretical vision outlined above.

Critiques

The first, and most immediate, theoretical problem is that this somewhat utopian vision is simply wrong. Put differently, the rapidly consolidating processes of globalization, namely, neoliberal worship of the free market (Harvey [2005](#)) and relentless consumerism, make it extremely unlikely that even intellectual progressives and their allies on the front lines of political activism can develop a consciousness to advance practical forms of collective praxis. Globally practiced neoliberalism may morph into libertarianism worldwide. The latter privileges the autonomous, self-regulating subject.

The second, and perhaps more dangerous, obstacle is the material plight of the “99%.” The occupiers of Wall Street (mentioned above) themselves are simply too economically disadvantaged to secure the human capital and necessity of free time to form the necessary political coalitions to successfully turn back the firm trajectory of widening economic and social inequality. Given the small numbers of academics, activists, and religious leaders (including Pope Francis), people still have to earn a living. Without a critical mass of middle-income practitioners, it is a real possibility that such an idealistic vision of collective praxis is not tenable or practical. An intellectually rigorous theory of change, such as the concept of collective praxis connotes, however, still remains necessary. In some ways it may be inevitable given the human tragedies that define the current global political climate.

Concluding Reflections

Social action embedded within a theory of collective praxis as well as radical developments in social theory resulting from postmodern and post-structural thought give rise to relational conceptions of identity, making intellectually plausible theoretically grounded understandings of collectivity. By extension, cultural studies can now embrace collectivity on the grounds of everyday lived cultural experience. Taking Foucault’s criticism of the autonomous (and socially isolated) subject to its cultural implications, scholars need not take the terrifying thought of “the death of the subject” negatively. Rather it affirms possibilities in the social imaginary that, indeed, collective praxis is not only feasible. It can be convincingly argued that a social epistemological understanding of identity, and agency, renders possible globally contextualized social action.

Introduction

A striking photograph introduces *The United States of America: A Hindu's Impressions and a Study*, published in 1916 by the renowned Indian anticolonial nationalist Lala Lajpat Rai. After a brief preface to the book, readers encounter a portrait in profile of a pensive-looking gentleman with a meticulously shaped mustache and a salt-and-pepper goatee. As the mostly capitalized caption informs us, this man is “Dr. W. E. BURGHARDT DU BOIS.”

It is no coincidence that the first image Lajpat Rai chooses to present – the image that spearheads this entire 416-page volume – is a portrait of a famous African American educator. Matters of education were of central importance to many Indian anticolonialists, and, in seeking to imagine forms of education conducive to national liberation and national uplift, many of these Indian activists turned to African American thought. Meanwhile, African American intellectuals took an intense interest in the Indian anticolonial struggle, using news of its twists and turns to construct (in a distinctly Vygotskian sense) new understandings of power and resistance along the global color line. This interest in the Indian independence movement was most famously expressed by W. E. B. Du Bois but was also avidly taken up by countless other African American scholars, including many faculty members at historically black colleges and universities (HBCUs).

Beginning in the late nineteenth century and extending through the first half of the twentieth, networks of African American and Asian Indian intellectuals forged transnational and trans-imperial political alliances and cultural affiliations rooted in a shared opposition to global white supremacy. In the heyday of overt Anglo-Saxon racism and imperial domination stretching across the Americas, Africa, and Asia, these African American and Asian Indian scholars, writers, and activists worked to construct what Nico Slate (2012) describes as “a colored cosmopolitanism that transcended traditional racial distinctions, positioning Indians and African Americans together at the vanguard of the ‘darker races’” (p. 2). While the term “cosmopolitanism” is etymologically associated with the idea of being a “citizen of the world,” its usage within the phrase “colored cosmopolitanism” more specifically highlights the subversive nature of alliances formed outside of established borders and boundaries.

“Education” is featured prominently within the discourses of colored cosmopolitanism. Asian Indian and African American thinkers exchanged ideas not only about different educational *methods* but also about the different *meanings* embedded within the notion of education. Given today’s increasing scholarly interest in the historical alliances between African American and South Asian peoples, it is worth calling attention to the central role of education – educational ideologies, educational projects, educational processes, and educational institutions – in the solidarities of colored cosmopolitanism. At the same time, for historians of education, an attention to these shared African American and South Asian histories can provide new and important perspectives on long-standing areas of interest within the field.

“Head, Heart, and Hand”: Booker T. Washington in South Asian Translation

Mohandas Gandhi considered Booker T. Washington’s Tuskegee Institute to be an ideal educational institution, and he repeatedly encouraged Indian educators to emulate Washington’s

work. As Nico Slate (2012) notes, Gandhi's high regard for rural and agricultural life and his emphasis on the dignity of manual labor were in part shaped by his admiration for Washington. Like Washington, Gandhi prioritized vocational education – agricultural skills, trades, and village handicrafts – as a path to “self-sufficiency.” Gandhi repeatedly echoed Washington's motto of educating “head, heart, and hand” and maintained Washington's emphasis on the “hand” (manual skills) and “heart” (religious and “character” education) as more important than the “head” (academic knowledge). Gandhi's language around education, and specifically on the relationship between vocational and academic education, was – like Washington's own career – complex and contradictory, and had certainly lent itself to charges of hypocrisy. Gandhi sometimes held up Tuskegee specifically as a model for “Harijans” (his term for India's so-called Untouchables), with the problematic implication that the emphasis on vocational training over academic learning was more suitable for Harijans than for other (more privileged) populations. Gandhi's famous 1937 “Wardha plan” for national education, however, did not include such caste distinctions; it promoted the idea of crafts and trades as central to the education of all Indian students. As Uma Dhupelia-Mesthrie (2004) points out, Gandhi's elevation of rural life and manual skills over extensive academic experience was reflected in the education he designed for his own sons – sometimes resulting in resentment within the family. He twice refused offers of funding for his son Manilal to study law in England, instead preferring to have Manilal stay at his settlement in South Africa, where the young man helped with farming, gardening, and the production of Gandhi's newspaper *Indian Opinion*.

While many of Gandhi's statements about crafts and trades highlight the notion of vocational training as inherently conducive to character building and as a vehicle for developing the intellect, it is important to note Gandhi's heavy emphasis on the *remunerative* nature of manual work – its potential to make each child into an “earning unit” and to make the schools themselves “self-supporting” through their students' labor (as

cited in Shukla 1998, pp. 77–78, 115). In this regard, Gandhi's emphasis on crafts and trades was rooted not in the desire to create particular “hands-on” experiences as developmental stepping stones but in the need to fund the schools. The question of school funding was an evergreen topic of conversation among Indian anticolonialists seeking to envision and enact a transition from a British-controlled society in which few children had access to schools to an “independent” nation in which schooling was free and compulsory. For the historian of education, the idea of making children produce saleable products to support their own schooling carries echoes of the gross exploitation that characterized, for example, the abusive US settler-colonial boarding schools for Native American children – the ignominious “Indian boarding schools” to which Washington's Tuskegee Institute has in fact been compared. Many Indian nationalists, however, viewed Washington's institute as a viable model developed for a situation they perceived as similar to their own dilemma, which revolved around the question of how to immediately provide some degree of “education” to oppressed masses of poor and primarily rural people long barred from formal schooling.

Gandhi, then, was not alone in his admiration for Booker T. Washington. As Slate (2012) notes, Washington's “legacy in South Asia was substantial” (p. 21). Writings by the famed Wizard of Tuskegee – including but not limited to his autobiography *Up from Slavery* – were “translated into multiple South Asian languages, including Malayalam, Marathi, Telugu, Hindi, Urdu, Gujarati, and Nepali” (ibid, p. 23).

The Anagarika H. Dharmapala, a Sinhalese Buddhist and a leader of the Buddhist revival in India, visited Tuskegee in 1903. In response to a journalist's query regarding his presence in the United States, the Anagarika described himself as “an admirer of your Booker T. Washington” and added “I expect to visit his institution during my stay here, and if I am successful I will pattern the Indian institutions after his.” The Anagarika, whose writings “emphasized group solidarity, material advancement, self-help, and education,” was also familiar with the work of W. E. B. Du

Bois and noted that Dr. Du Bois “took a different view” from Washington. But the Anagarika’s perspective regarding these differences, as he wrote to Washington, was that “On the whole it is healthy that two parties are at work on two different lines; and there is no energy lost. The moral, political and industrial development are the three sides of a triangle” (as cited in Harlan 1983, pp. 278–279).

The Anagarika’s understanding of Washington and Du Bois as “two parties at work on two different lines,” each contributing to a balanced “triangle” of group uplift, is indicative of how the “Washington–Du Bois debate” was reworked in the translation to South Asia. Rather than understanding Washington and Du Bois simply as two men who had a “debate” with each other – necessitating that all listeners pick a side in the debate – many South Asian educators and theorists drew inspiration from *both* of these African American educational leaders. Even Gandhi, whose educational ideology was so closely patterned to Washington’s, also admired (and corresponded with) Du Bois. Gandhi favored Du Bois’ refusal to compromise with white supremacy in any form, and Du Bois – unlike Washington – was an avid supporter of all aspects of the Indian independence movement.

A Hindu’s Views: Lala Lajpat Rai and African American Education

Lala Lajpat Rai, whose *The United States of America* is largely devoted to questions of education and racial struggle (sometimes as two separate topics, sometimes intersectionally as with particular issues concerning “Negro education”), delved deeply into the questions at the heart of the “Washington–Du Bois debate.” Nevertheless, the actual expression “Washington–Du Bois debate,” so familiar to US education historians, was never used by Lajpat Rai. Rather than present his Indian readers with the image of a duel between two black men vying for the right to shape the future of their race, Rai provided a detailed and nuanced discussion of various trends within Negro education, contextualized within a historical framework

that included the criminalization of black literacy in much of the antebellum United States, the brutality of the post-Reconstruction era, and the twentieth-century reality of a separate-and-unequal racial regime in which vast numbers of African Americans were still denied access to any schooling whatsoever. In discussing the educational models developed by African Americans to deal with these conditions, Rai emphasized the potential applicability of such models to the Indian anticolonial nation-building project.

Lajpat Rai discussed Tuskegee at length and in overwhelmingly positive terms. He also quoted extensively from interviews with Washington and from written material provided by Washington. At the same time, Rai also paid much attention to African American scholars such as Kelly Miller, Dean of the College of Arts and Sciences at Howard University, who strongly critiqued the prevailing societal pattern of reducing support for African American higher education and systematically directing African American students toward vocational training. Following Kelly and others, Rai noted that much of what passed for “vocational education” was not really education but a way of keeping African Americans in menial labor. Rai did not, however, blame Booker T. Washington personally for this problem – rather, he cited the overt racism of white southern policymakers and the misguided paternalism of white northern philanthropists. Ever aware of the problem of educational funding, Rai realized that educational policy was largely determined by those who had the capital to finance that education.

Rai specifically compared African American *women’s* education to Indian women’s education, declaring that African American women’s education was superior in both quality and quantity and urging Indians to emulate African Americans in the provision of education for women. He noted that at major African American colleges like Howard and Atlanta University, half of the students were female and that almost all African American educational institutions were open to women as well as men. He was also impressed by the high quality of many all-female colleges constructed by African Americans.

Lajpat Rai's greatest admiration was reserved for his friend and colleague W. E. B. Du Bois. While Rai did advocate for more industrial education in India, along the lines of Tuskegee, he ultimately agreed with Du Bois on the pressing importance of preparing students for higher academic studies and of making university education available for those students who wished to pursue it. Further, Lajpat Rai was greatly impressed with Du Bois' political activities – his critical writings in the NAACP journal *The Crisis* and his civil rights work – which could also be regarded as forms of public education. Lajpat Rai's *The United States of America* reproduced lengthy selections from Du Bois' writings. The two men continued their friendship through written correspondence after Rai returned to India (ending a 5-year stay in the United States) in 1919. Du Bois sent Lajpat Rai copies of *The Crisis*, which Lajpat Rai both circulated among his fellow Indian anticolonialists and quoted from in his own writings. In 1928, Du Bois wrote to Rai about a novel he was working on, called *Dark Princess*. The novel was a political love story in which an African American man, Matthew Towns, marries an Indian woman, the “dark princess” Kautilya of Bwodpur. These lovers have an Afro-Indian son, Madhu, who is destined to become a unifying force leading the “darker races” to universal freedom. Du Bois mailed portions of the manuscript to Lajpat Rai for feedback. Rai sent Du Bois comments on the excerpts but may not have gotten to read the final published novel: he died in November of 1928 after being severely beaten by police during a silent march protesting British colonial policies.

Historically Black Colleges and Universities as Centers of Colored Cosmopolitanism

Historically black colleges and universities (HBCUs) played a central role in the phenomenon of colored cosmopolitanism. The HBCUs were important to these transnational solidarities for several reasons. For one thing, HBCUs were centers of African American political and intellectual

life. For South Asian anticolonial nationalists in the United States, visiting HBCUs was a way of connecting with communities of fellow “colored” people who were both supportive of Indian anticolonialism and interested in sharing information and analyses regarding their own political struggles. Lala Lajpat Rai, in conducting his extended study of African American education, relied on the intellectual collaboration, and in some cases the personal hospitality, of professors and administrators at HBCUs such as Morehouse College, Howard University, and Atlanta University (as well as at institutes such as Hampton and Tuskegee). The Indian anticolonial nationalist Krishnalal Shridharani, author of *War Without Violence* (1939) – a book regarded as a major source of inspiration for African American civil rights activists of the 1940s – had the opportunity to share his anticolonial views with a host of future educators when he was invited to deliver the commencement address at the historically black Cheyney State Teachers' College in 1942. Cedric Dover, an anticolonial activist of mixed Indian and English heritage, served as a visiting lecturer at Fisk University in 1947. Dover's friendships and collaborations with African American artists, writers, and scholars – many of whom were associated with various HBCUs – allowed him to develop nuanced and historically grounded understandings of race and resistance, which were reflected in his many published works.

The well-known anticolonial activist and social leader Ram Manohar Lohia, during his two visits to the United States (1951 and 1964), also relied upon a network of HBCUs to help him connect with African American scholars and activists. Lohia's first speaking engagement in 1951 was at Fisk University in Nashville, Tennessee, where he was a featured speaker at that institution's annual Race Relations Institute. After his speech, Lohia lunched at the home of Fisk University President Charles Johnson, a longtime ally of the Indian independence movement. During the same trip, Lohia visited Howard University, where he gave a talk dealing with race, caste, colonialism, and civil disobedience. At Howard, Lohia dined with that university's President

Mordecai Johnson, another firm ally of the Indian independence movement, who had traveled to India and met with numerous proponents of *satyagraha* (nonviolent direct action). On Lohia's 1964 trip, he visited Tougaloo College in Mississippi, where he had long conversations with members of the Student Nonviolent Coordinating Committee and their faculty supporters. The students were preparing to launch the Mississippi Freedom Summer, and they discussed planning and strategy at length with Lohia, an experienced activist who had spent a total of 6 years in British jails for his anticolonial activities. Interestingly, Lohia's traveling companion during large segments of his two trips to the United States was the civil rights activist Harris Wofford. Wofford, though white, was also a product of an HBCU: the first white man to earn a degree from Howard University School of Law.

HBCUs provided opportunities for many South Asian activists to not only learn about African American civil rights activities but also in some cases to demonstrate their support through personal participation. Lohia, during his 1964 visit to Tougaloo, was arrested for refusing to leave a whites-only cafeteria in Jackson – an action he had discussed earlier with a group of Tougaloo students, who had assisted Lohia's action by driving him to the cafeteria. When Lohia later received an apology from the State Department for his arrest in Jackson, he responded that the point of the action was not to make a statement about his own position as an international visitor but to oppose the Jim Crow system that African Americans faced on a daily basis (and for which they certainly did not receive any apology from the federal government). Tougaloo was the academic “home” to several South Asian faculty members who similarly participated in civil rights activities alongside African American students and professors.

Since HBCUs were major intellectual and political centers where Indian and African American activists could connect and exchange ideas with each other, it is perhaps no surprise that many of the Indian independence movement's strongest supporters were professors and/or administrators at HBCUs. George Washington Carver, a

professor of botany and agriculture at Tuskegee, avidly supported Indian anticolonialism; he met with Lajpat Rai and corresponded extensively with Gandhi. Charles S. Johnson of Fisk corresponded with leaders of the Indian National Congress. Numerous professors from Howard corresponded with Indian activists; one of these professors was Benjamin Mays, Dean of Howard's School of Religion, who traveled to India and met with many leaders there, including Gandhi. Mays later wrote to members of the All-India Women's Conference and offered to make a financial donation toward that organization's efforts on behalf of Indian women's and girls' education. Howard Thurman, also of Howard University, traveled to India as well, also meeting with Gandhi. In addition to the participation of numerous professors, several schoolteachers became involved in colored cosmopolitanism. These included Mary McLeod Bethune, the elementary school teacher who founded her own school and eventually became a nationally known educational and political leader.

An Emerging Area of Study

The past 10 years have seen a rapid acceleration of scholarly investigation into the historical imbrications of South Asian and African American communities, organizations, intellectual genealogies, and political movements – a complex web of mutually constitutive relationships that both predate and extend well beyond the simple connection generally drawn between MK Gandhi and Martin Luther King (Bald 2013; Horne 2008; Slate 2012, 2014). These transnational histories represent an important area of exploration for future work in cultural studies. Pointing to the limitations of analyses that position “class and culture as a localized, nation-bound set of interests,” Cameron McCarthy and Jennifer Logue (2012) call for greater attention to the “patterns of transnational hybridities” that characterize contemporary social life (pp. 5, 41). Recent scholarship on the linkages between South Asian and African American communities demonstrates the

importance of attending to transnational circulations and hybrid formations, not only in contemporary cultural studies but in historical cultural studies as well.

Scholarship on the interconnectedness of African American and South Asian cultural and political histories should continue to unfold in multiple directions in the years to come, with important implications for the study of education. Just as explorations of colored cosmopolitanism would be incomplete without an attention to the central role of education – educational discourses, educational practices, and educational institutions – historians of education must take into account the histories of these transnational influences and solidarities. Particularly today, when national and international discourses and structures of race increasingly use the notion of “education” as a wedge to divide South Asian and African American communities and to pit these communities against each other – via a “model minority” myth and anti-black deficit discourses, both of which largely revolve around assumptions about education – it is imperative that students, teachers, policymakers, and scholars of education consider these historical linkages of colored cosmopolitanism and the classroom.

Introduction

Mentioned as bridge between premodern and modern thoughts, Comenius literally lived a life in between. Born 1592 at Nivnice (Moravia), his life was concerned with the effects of disintegration of Europe's order especially through the Thirty Years' War – moving him between European places, thoughts, and movements. Orphaned at 12 years and losing his first wife and children through pest, he was a traveling and moving person, related to important places and persons of his time. He studied at the Calvinistic Higher School in Herborn (1612–1614) where he came in touch with Ratke's proposals for language lesson and the encyclopedic endeavors of his teacher Alsted. He finished his scholastics out of money in Heidelberg, leaving home via Nuremberg where he purchased a script of the Copernican theory. Being a priest and later on the last bishop of the “Unity of Brethren” (a Moravian reformist congregation), he contacted the Swedish King in hope to arrange a settlement for the return of his congregation to Moravia and traveled to Hungary in this concern. Well discussed and often invited all over Europe, Comenius was requested to found colleges in England, France, Sweden, and Poland, what often did not take place for several reasons,

among them war and Comenius' rejections. He met Descartes and stayed in contact with the new founded Royal Society Academy in London. For a long time he lived exiled in Leszno (Poland). After the burning of the town and his library, he moved to Amsterdam, where he died in 1670.

Comenius was entangled both with the upcoming modern scientific approaches and with the theological movements which were engaged in grounding a universal Christian way of living. This, sometimes mentioned as "third force" in the seventeenth century, approach aimed at a scientific reform orientation in line with theological-based certitude (cf. Popkin 1992). In Comenius' concern, this led him to expose his philosophical, theological, and pedagogical thoughts in an integrated and overarching system called *Pansophia*. The encompassing aspect of *pan* indicates his dedication to overcome the confusion and disarray of his time by leading the human beings to their humanity founded in God's creation. Embedded in this metaphysical-theological standpoint, Comenius developed an analytical epistemology of human comprehension as *imitation*. He elaborated a holistic concept of teaching everyone, everything in respect to the general (*omnes, omnia, omnino*). With *Orbis Sensualium Pictus* (*The Visible World in Pictures* cf. Comenii 1658), he published the first illustrated book for lesson unifying language teaching and teaching the order of the world. Further his engagement for general education, public, and associated research as well as his plea for general counseling in concerns of science, politics, and religion made his work to be a source of rereads throughout the last 350 years cf. for example Zemek et al. 2008; Gouris et al. 2015; Schaller 2004; Hericks et al. 2004). He often is mentioned as a pioneer of didactical and pedagogical reflections about lesson, sometimes without considering the difference between premodern and modern notions.

Omnes, Omnia, Omnino: Comenius' Lesson on Teaching the World

Based on his pansophic (overall wisdom) scheme, Comenius argued for general education without

any limitation. His educational principles to teach everyone everything regarding the general (*omnes, omnia, omnino*) arose from the notion of equality of every human being as part of God's creation. In this regard, he started in 1623 in his exile in Poland the Czech-Latin schoolbook *Januarum porta lingua* Comenius (1631/1642) expecting his return to have the opportunity to rebuilt the "Bohemian Church" and work on the continuation of the divine order on earth. This encyclopedia, later supplemented with pictures for his most famous work, *Orbis Pictus*, aimed not only to give names and significations in a popular language but to show the whole world in its elements and their relations – this is the point of *omnia*. Complementary he claimed, addressing *omnes*, the right of education for every child, regardless of gender, as well as for poor, rich, disabled, young, and old. This claim stood in the European context of reordering the social throughout the increasing force of citizenship displacing nobility and clergy from their political and social force. Yet, the prefix *pan* in his pansophical work not only describes his philosophical-theological point of view but also his educational standpoint. It is about the trans-particular wholeness of the divine creation (*omnino*), where the human's position is one element of others. In the original edition of his famous book *Orbis Pictus*, the human being is posed neither in the beginning nor in the end. It is posed in between as one element of the whole world. Yet some of the translations and copies in later editions changed this order and put the pages showing the human being at the beginning. That was not Comenius' concern; unlike the following modern thinkers of the Enlightenment, he was not engaged in evolving the solitary position of the modern *ego*. Still his philosophy was part of the shifting move that transliterated the notion of human's nature as sinful into its similarity to God. The renaissance and humanistic concept of the *imago dei* based humanity on the active freedom of creating the world along the divine order. In this line Comenius mentioned his notion of *pan* as an encompassing view of the world. In Comenius' view the world is not divided in fields of philosophy, politics, and religion – yet those fields

are intertwined through the human collaboration with God (*collusor Dei*, cf. Buck 1984; Trembl 2001). The relating hinge between God and the human being is a certain scope of cognition – *imitatio* – including sense, speech, and faith. This trinity grounds the necessity of an analytical and both methodical system of teaching and learning. As much as this methodical reasoning about lesson associated his work with the new arising modern scientific approaches, it advanced his reputation as a classical pedagogical thinker.

Philosophical Education: *Pansophia* and *Pampaedia*

Though posing the very modern question about the special position of the human being, Comenius founded the answer in a very premodern, universally, and eschatological-orientated base of divine order. Thus the difference and the similarity between humans and God were the center of his philosophy aiming to rebuild a world where peace and solidarity are possible. Yet Comenius took his step not from the active site of the human but from the divine ordered world. The divine creation in its wholeness has to be known in a thorough way to avoid discord and war. In that way he did not center – at the threshold to modern thought – the world around the recognizing subject but posed the human being as part of a transcending order that is ruled through the relationships between the single elements and their relation to the true ideas. In Comenius' epistemology, the idea (archetype, *exemplar*) is threefold entailing the idea (*idea*), the realization (*ideatum*), and the mode or instrument of its performance (*ideans*). The ladder is read by Comenius as the senses (*sensus*), the technical modes of its production (*manus*, hand), and the language (*lingua*) of (re)producing the archetypal idea, which indicates Comenius' Neoplatonic position.

Comenius' explanation of the experienced disarray through religious wars arises from the picture of Babylonian distortion in the *Labyrinth of the World* that needs to be cleared to the *Paradise of the Heart*, as one of his earlier works reads (cf. Comenius 1631/1998). In this way he is in

line with his Renaissance contemporaries by renewing the theological-metaphysical requirement of remembering the truth of divine order. Nevertheless, the order of creation is not considered as self-fulfilling but needs to be recognized and continued by the human being. Based on his experiences of the great Thirty Years' War following the reformation of the Christian Church, Comenius aimed for a divinely ordered world where the rationality of God's harmonious creation needs to be known by everyone. This modern way of merging the individual as active part shows why Comenius' philosophy as *Pansophia* inevitably unifies epistemology, politics, and education – his educational system therefore reads *Pampaedia*.

From this point Comenius' educational aim preserves the necessity to learn to know the order of the world. His systematical proposal is in itself built up as a representation of this order. His didactical view advises to learn at first examples (*exempla*) before stepping to regulations and consolidation. The examples are – different from sensualistic and phenomenological standpoints – not only the sensed base which structures the way from the special to the general. The example itself embodies – in a mere realist position – itself the *exemplar* (idea, origin) and *exemplum* (copy, replica) and therefore enables the learner to emulate and imitate (*imitatio*). It is the *imitatio* which contains Comenius' notion of cognition. His epistemology therefore is a trinity of induction and deduction held together by the operation of *syncretis*. The syncretic mode of cognition unifies the motion from particular to general and vice versa through comparing the similarities. The axiomatic general is not a final point of abstracting through thinking. Rather it is the effect of recognizing literally seeing the example: imitating (*effigiare*), knowing (*scire*), and abstracting (*abstrahere*) coincide. In Comenius' view, there is no ontological difference between the origin (*exemplar*) and the copy (*exemplum*), as well as there is no gap between the presence and representation. To see something means to recognize its true essence – a philosophical position that draws him away from his modern scientist contemporaries which like Bacon or

Descartes supposed the cognition as stepping from the sensed particular to the axiomatic general.

Against this background education and lesson is about showing the world and its divine ordered structure. Education is a relational activity between the instructing teacher, the learner, and the wholeness of the world. Comenius conceived learning as the dual activity of rebuilding and receiving. Comenius therefore privileges the example. A particular element itself is related to the whole and Comenius' advice to step from the particular to the general stands not for proceeding to a cognitive enlargement. Rather it corresponds to his metaphysical standpoint that the divine ordered truth can be understood in its elements – which are intertwined and referring to the harmony of the whole picture. Going along with this education is in itself action and recognizing. In that sense learning the divine non-subjective (in a modern sense of subjectivity) order of the world entails all at once ethic and metaphysic aspects. Learning to know the world means at the same time to know how to live well in regard to the trans-particular. As Comenius conceives the order of the world as divine harmony, there is no reason for him to think change and human activity different from an objective teleology of fulfillment and continuation of God's work – in that way his philosophy can be characterized as subjectivism (cf. Patočka 1971).

Knowledge, Science, and the Spread of Formal Learning

There are at least three points that outline Comenius' stance at the threshold to modernity in respect of the spread of modern science and education: At first, regarding the methodological aspects of teaching and learning, Comenius' philosophy was linked to the establishing of new institutions of science. Following on the one hand the methodical mode of thinking and representing knowledge by well-ordered systems, Comenius on the other hand rejected the particularity of the modern scientific approaches. In this manner, the *omnino* plays a decisive role in

Comenius' epistemology since the particular elements of knowledge such as laws of nature for Comenius never were self-contained or grounded in human cognition but considered as part of a transcending order. Thus Comenius all at once could address and problematize the analytical and methodical approach of modern science. Unlike Descartes and later the rationalist empiricism or Kant's epistemology, Comenius' view on cognition and learning was not about gaining independence from social and natural boundaries. Rather on the contrary Comenius conceived learning and achieving knowledge *as* partaking in the world. Only in that sense learning leads to humanity and enables to emend the confusion of the world he and his contemporaries had experienced. Comenius' strong plea for public and general education has its source in this conjunction of cognition, action, and politics, where ethics are included in the process of cognition (and not an effect of it).

Secondly, Comenius could address the upcoming new order of a modern society. Signed by war, destruction, and rearranged classes, there grew diversified needs for communication and institutional ways of deliberating knowledge. Comenius' work *Orbis Pictus* and the earlier written Czech-Latin *Janua* combined the new medium book by picturing elements of the world and signifying them in Latin and in Czech. The *Orbis Pictus* was through hundreds of years the most used book for lesson and has been translated in different languages all over Europe. This mediatized mode of lesson uncoupled the medium from its author's subject to show the unique order of God's creation. Similarly, his commitment for general education outlived him as well. His *Pampaedia* mentioned the importance of early education long before Rousseau proposed the difference between childhood and adulthood. Comenius considered schools as "workshops of humanity," implying a lifelong path of eight schools from childhood to seniority. Along with this his work was associated with establishing public science, among these correspondences with other scientists, founding schools and higher schools, and his involvement with scholars across Europe.

Thirdly, Comenius' understanding of active learning advanced the modern institution of school. Yet his notion of lesson was to learn about the world's order to the core of its improvement and emendation: His major work's title is programmatic in that sense: *De rerum humanarum emendatione consultatio catholica* (General Consultation on the Improvement of Human Affairs; Comenius 1670/1966). These seven subdivisions include work which was lost over hundreds of years and rediscovered in 1934 in Halle/Saale having been stored there since the eighteenth century in the library of the Franckesche Stiftungen. It contains, i.a., the earlier published *Panorthosia* (Universal Reform), the *Pansophia* (Universal Wisdom), and the *Pampaedia* (Universal Education), and its reappearance broadened the view on Comenius' philosophy beyond his function as mentor of modern didactics.

Present Traces to Comenius' Philosophy of Education

There are some lines in Comenius' work that are – though premodern shaped – worth to be linked to contemporary topics. Comenius' question about our ways of relating to the world, to others, and to oneself makes it both easy and difficult to stick to Comenius – albeit his conclusions. According to the question about the relationship between humans and the order of the social – to put it in modern words – Comenius provided a programmatic view in stressing out a non-individual yet broader perspective regarding the relationality of worldly elements in his pansophical emphasis on the *omnino*. This kind of pre-communicative space (cf. Schaller 2004) of being related as part of the divinely created world stretches in a way forward to the modern notion of the public as a site beyond particular reasons and wills. In addition Comenius' philosophy of a relational order of particular differences entails a nearness to (post)modern themes of difference and otherness – though Comenius founded all differences in the universal order of divine truth. He conceived human affairs as taking part in the

divine order (*conscientia*), whereas the modern issue of solidarity is based on the heterogeneity of individuals. Comenius' Neoplatonic view of education and humanity presupposes participating at the general and unchangeable order of truth – alike Plato's relation between the absolute truth of ideas and the need of the human's turning move toward them for accomplishing political-practical effects. This stance allowed him to problematize the modern scientific attempt of treating knowledge without regarding its relation to the world and interdependent boundaries. Comenius' insisting on taking into consideration the relationship between particularities and transcending the particular involved his approach with the beginnings of establishing public science, e.g., the Royal Science Academy in London. Yet his educational philosophy aimed following – methodical and analytical – the path of twice transcending and relating the human being. In this way his modern use of representing media – books, language, pictures – was strictly tied to the worldly and divinely aspect of knowledge and science. Albeit Comenius' philosophy of education was constitutive founded in his theological standpoint about the human's similarity to God, Comenius' advocacy for establishing general and formal education was in the nineteenth century used as reference to advance the professionalization and academic reflections of educational practices. On the contrary to the modern notion of education by sticking to the individuality of every person, Comenius attempted to address everyone *as part* of the project of emending the human affairs (*“de rerum humanarum emendation,”* cf. Comenius 1670).

Comenius' traces were followed surpassing his interest in ordering the world and the human matters and often ignoring the background of his metaphysical standpoint in the modern ways of deliberating knowledge. This is apparent in his stance as pioneer of a media-based way of showing the world and providing the tools of comprehending the world by one's own thoughts and cognition. Further, Comenius' commitment for equal access to education sometimes is associated with the modern issue of finding a way to remove inequality. Facing Comenius' experience

of war, epidemics, and displacedness, it needs no much effort to see the requirement of worldwide solutions – discussing, debating, and emending the fields of science, religion, and politics. In this manner Comenius suggested a European and global council of yearly meeting envoys of these three fields, which turned him into a mentor of modern questions of world peace (cf. Korthaase et al. 2005; Gouris et al. 2015).

Being located in the axis between premodern and modern thoughts, there is the topic of translation that is brought up with considering Comenius as an educational thinker. Translation was one of the main topics of his work. It occurs in translating the order of the world into pictures and names in different languages, as well as in his connections to a lot of thinkers of his time spread over Europe. Against this background Comenius' work seeks a way of transcending the local and particular in order to share solidarity. In addition there has to be considered Comenius' notion of difference in unity – regarding the complexity of his work, the addressed fields, the different levels of teaching, learning, etc. Comenius' philosophy based unity on a divine and universal order by stressing the *pan* as aspect of uniting or grounding all differences.

Conclusion

Though Comenius' sketch of a metaphysical-founded world needs to be read in its context without reducing his lines to modern concepts as too familiar, it is obvious that in transferring his framework in our present, it entails some intriguing aspects. First of all there is the issue of relating to the historic frame of modern concepts like individuality and subjectivism addressing the need of translation. Secondly, despite the gap between his metaphysical-theological epistemology and the modern notion of subjectivity and contingency, Comenius' theory of a worldly and non-egological concept of humanity raises questions of relating to the world and participation. This includes the public educational system addressing the notion of equality (*omnes*), sketching the notion of general education

(*omnia*), and moreover addressing the problem of being with others (*omnino*). Thirdly, it is Comenius' scheme of cognition as *imitatio* unifying, imitating, and innovating that lays – interrupted – traces to postmodern concepts of difference, relationality, and particularity. Insofar as education and *Bildung* are shaped as transformational actions in a non-egologic manner but as partaking in the world, there are links to present concepts of the relation between human beings and the social. At last, bridging the gap between the centuries and transformations in philosophy of education, there still is to be raised Comenius' question how human affairs can be discussed and counseled in respect to the *omnino*.

Competition and Fair Play

Graham McFee

University of Brighton, Brighton, UK
Department of Philosophy, California State
University Fullerton, Fullerton, CA, USA

Synonyms

FIFA

Introduction: Competition Is Characteristic of Sports

Competition is arguably characteristic of sports. At the least, if there are noncompetitive sports (or if the most readily translated word “sport” in some European languages applies also to some noncompetitive physical activities), a fairly clearly demarcated class of activities thought of as *sports* does centrally involve competition between individuals or teams, typified by the activities included in the Olympic Games (and similar competitive structures: the FIFA World Cup in soccer, the Super Bowl in American football). The resolution of such competition may differ in those sports where the *manner* of attaining the goal whereby one is successful is fundamental (what David Best 1978 called “aesthetic sports,” typified by gymnastic vaulting or ice skating) by contrast with those sports where the manner of achieving the “aim” is irrelevant as long as it is within the rules of the sport (and hence varied) – true of the vast majority of sports, including soccer, gridiron football, rugby, netball hockey (both ice and field), basketball, golf, tennis, and many more (Best’s “purposive sports”).

Two Metaphors for Competitive Fairness

In both cases, the rules of the sport regulate competition in that sport; the commitment to play

sports is a commitment to play by the rules. More exactly, one must play by the rules in their constitutive uses (the aspect that permits, say, try scoring in rugby by designating certain behaviors as the actions required for success in the sport) since some of the rules of sports typically also have regulative (“penalty-invoking”) uses. But although sports have been compared with warfare, the comparison is misleading precisely because sports should be played in a sporting fashion. That is, one should be a *good sport* and behave in a *sportsmanlike* manner, even if much sport is not played in this spirit; the aim should be *sportsmanship*, not *gamesmanship* – terms that seem only to exist in the masculine, no doubt reflecting the (distant) history of sports. For the behaviors involved are clearly moderated by the (broadly) voluntary character of participation in sports (except in school!) and by both the rules of the sport and the recognition that sports are governed, in two ways, by considerations of *fairness*: as typified by governing metaphors that there shall be both *fair play* and a *level playing field*. Each aspect is important, providing a justification of the concerns of the rules in typical sports so that teams start with roughly equal chances of victory, the playing field will literally be level (if some other things would give one side an advantage), or, if this cannot be managed, the advantage will be evenly distributed – say, by changing ends at half time. This also explains why some sports have divisions by weight, age, or disability: to give all competitors a roughly equal chance. Thus, the organizers in the first world championships for the laser dinghy provided new boats for all competitors to preclude anyone gaining an advantage in this way. Of course, such a strategy could not be applied to Formula One racing cars, since the teams aim precisely to produce the best car, but many of these regulations in place there are designed to set parameters within which innovations are permitted (say, as to engine size). So fairness here amounts to attempts to minimize the competitive advantage given by the situation prior to the beginning of the competition.

Although the account of *level playing field* is in this way relatively straightforward, the other metaphor, *fair play*, is somewhat more complicated to

cash out, despite many rules in a typical sport being explicitly designed to encourage *fair play* and referees or umpires often being tasked with ensuring (perhaps trying to enforce) *fair play*. While most sports permit the sketching of a commonsense notion of playing fairly (and especially of playing unfairly), typically it must be elaborated case by case. In snooker, for instance, since an advantage may be gained by touching the cue ball with the cue prior to making an actual shot, a rule precludes doing this and enjoins one to tell the referee should he/she do so accidentally. *Fair play* requires admitting to the action in this way; and the referee will penalize one if he/she fails to do this. In rugby, the referee is "... the sole judge of fact and of Law during the match" (Laws of Rugby Union [6. A. 4 (a)]) and one specific concern is with "Acts contrary to good sportsmanship." Indeed, the International Rugby Board is explicitly committed to *fair play*, explaining the contrary (*foul play*) as "... anything a player does within the playing enclosure that is against the letter or the spirit of the Laws of the Game. It includes obstruction, unfair play, repeated infringements, dangerous play, and misconduct that is prejudicial to the Game."

But what fair play requires may differ in contexts as well as between sports: for instance, reflecting the skill level of players. Thus, in cricket, any ball bowled should be "... sufficiently within ... [the striker's] reach for him to be able to hit it with his bat by means of a normal cricket stroke" (Law 25.1 {b}). If it is not, the delivery is deemed a *wide*, and then a run is awarded to the batting side and the delivery must be repeated. Here, notice two features: first, in line with a generalized "fair play," the batter must be given an opportunity to display his/her skill and second, the requirements here are specific to the player, since what delivery so-and-so is "... able to hit with his bat by means of a normal cricket stroke" may differ from what is possible for a different player. The rules permit that difference be acknowledged through what the umpire will or will not designate a *wide*. So here we have a rough idea of fair play and recognize some difficulties in applying such a notion equitably. Still, the general idea is clear: that neither side should gain

competitive advantage by contravention of the rules and that the spirit of those rules circumscribes the competition.

General Considerations of Fairness

Moreover, in many sports, general considerations of fairness are pervasive. Thus, the rule in baseball that the batter is out after three strikes implicitly recognizes, first, the need for some regulation; second, a reasonable time requirement (three hundred strikes would make games longer than the designers think desirable); and third, the idea that batters should be given the opportunity to display their skill – only one strike for an out would be unfair in not permitting this.

At the least, considerations of fairness can connect to competitive advantage. Thus, in de Coubertin's mind at least (see McFee 2015a, pp. 148–153), a concern with fairness provided the primary motivation for the amateurism rules for Olympic Games. Certainly de Coubertin (2000, p. 309) worried that "a mercantile spirit threatened to invade sporting circles" in the form of the kind of betting that might encourage match fixing. Yet this was not his primary motivation for requiring amateurism; instead, that concerned the avoidance of competitive advantage in ways he thought unfair. Two cases should be considered: the first is the man whose occupation is, say, a rower is precluded from competing as a rower. The second case, addressing the person with no occupation, has the same motivation: "... [t]he man who can devote all of his time to training is bound, nine times out of ten, to beat the man who lacks this opportunity" (de Coubertin 2000, p. 642). De Coubertin (2000, p. 650) called these "false amateurs." And the Olympics during its so-called amateur phase were dominated by precisely these "false amateurs" as professional students or members of the armed forces (as well as the children of rich parents).

Additionally, the kinds of slogan regularly applied to sporting contexts – such as "May the Best Man Win" – recognize that one team will typically (and perhaps only on that occasion) have a competitive advantage over the other. But the

outcome is not always predictable. If this were not so, we need not bother with the matches. Yet, in looking for the best team, what person knowledgeable about baseball would have voted in 2014 against the LA Angels of Anaheim? They seemed all-conquering: that was what their regular-season record suggested. Their defeat early in the play-offs illustrates the unexpected result, or upset, without unfairness.

Two Uses for Rules

That rules *prohibiting* certain behaviors mention in their formulation those very behaviors might seem to entrench those behaviors in the rule structure of the sport. Then breaking the rules, by performing such behaviors, can seem a way of adhering to the scope of those rules. Against this view, some theorists distinguish the *constitutive rules* of any sport (those that bring into being the actions of which the sport is comprised) from its *regulative rules* (those invoking penalties for rule breaking). But such a distinction is very difficult to draw, and sustain, in practice: for instance, one might think the “handball” rule fundamental to the character of soccer might make it seem a constitutive rule. But there are sets of penalties for handball, so it *seems* a regulative rule. Now the whole distinction looks suspect. However, one might better say (as above) that some rules have constitutive uses (and perhaps regulative ones too), while some rules have regulative uses. Then the specifics of the occasion must be addressed to determine whether the force of the rule on this occasion is primarily constitutive or primarily regulative.

Further, written rules are often given a particular “reading” in certain contexts; thus, the rules of basketball explain it as a noncontact sport. But contact is very much a part of the sport as one watches it in, say, the American Basketball Association. Some writers have seen this as reflecting an ethos of the sport (D’Agostino 1995), yet it is probably as easily treated as a contextually specific reading of those rules (McFee 2004, pp. 59–64); otherwise, one must ask about the normative force of the ethos.

Sportsmanship

Of course, to disregard all of the rules, or even all the rules in their regulative uses, would not be to play the game. But that is not the case here. And no doubt certain forms of cheating, if they became widespread, would affect the game. Thus, “lifting” in the rugby lineout was contrary to the rules, but it became so widespread in the game at a high level that the rule was changed; after all, if everyone was doing such and such, there was no advantage to be gained by doing it (one had already got that advantage). Permitting “lifting” in the lineout thus spoke to anyone who had not previously behaved (badly) in this respect; considerations of fairness are important in such rule changes.

The reality of sports often falls short of the standards of sportsmanship set by requirements of fairness. Inevitably, not all sports players feel equally bound by considerations of fairness, and the importance of the occasion might have a bearing in Diego Maradona’s infamous “Hand of God” goal for Argentina against England in the 1986 FIFA World Cup which should not have been awarded by the referee (since it was clearly a handball). Equally, if the referee had not noticed this fact, considerations of sportsmanship should have required acknowledging its rule contravention. The importance of the event may explain, without mitigating, Maradona’s misconduct. No doubt the economic impact of success is one key factor. But surely taking part in the sport involves at least some commitment to the rules of that sport, even in their regulative uses. Hence idealists here will ask why players play the game (i.e., join in with the sport) if they are not interested in “playing the game” – that is, in considerations of fairness in their playing.

Extent of Obligations

Yet what are the limits to one’s obligations here? The case of racquetless Josie poses this question sharply. Josie arrives at the squash tournament without her racquet. You have a spare; are you obliged to lend it to her? And does it make a

difference if "... without her, you would almost certainly win the championship" (Butcher and Schneider 1998, p. 4) while the game against her will be tough? If one thought that there was a contract implicit in our agreeing to play squash together (as above), that contract reaches only so far – I will not be breaking it in failing to lend her the racquet. On the other hand, the temptation to think that I ought to lend her the racquet (indeed, to give her my better racquet and use the spare myself) also has a basis in (general) fairness. But it is not in the same way an obligation within the sport – any "obligation" is supererogatory.

Notice, too, that obligations to the sport seem to extend beyond the playing field. No doubt there are issues concerning the doping rules in professional cycling, as manifest in Tour de France, and no doubt there were times in the history of the sport when such doping was widespread. However, misconduct here seems especially heinous when one protests loudly that one is "clean," as Lance Armstrong did, and continued doing so in the face of contrary evidence. The same idea seems to apply to Marion Jones, the Olympic athlete who (so she said) felt the pressure to win to such a degree that she slipped into doping. Here, the importance of sports players as models for behavior connects with how the rules should be interpreted. Additionally, there are often rules within sports (which players implicitly agree to play by) as well as moral concerns, say, with fairness. If Tom Brady knowingly played with a less than fully inflated football in the 2015 Super Bowl, and did so to gain competitive advantage, that would be cheating – even if, since we only discover it after the fact, we cannot correct the situation during the match. The importance of the event for some fans can seem to give the "Deflategate" case, like these others, an additional significance. But, first, there have always been such cases in sports: thus, in the so-called Pine Tar Incident (Russell 2004, pp. 94–95), a bat was ruled illegal (by virtue of pine tar on the bat) even though all sides agreed that no unfair competitive advantage was gained from this tar. Having used the illegal bat to hit an apparent home run toward the end of the game, that batter was out and his team (the Royals) had lost the game. When Lee

MacPhail, President of American League baseball, decided that, since there was no advantage, the wrong action had been taken, he ordered the home run to be reinstated and the rest of the game to be replayed from there. Whatever one thinks of his decision, it highlights graphically the difficulties that result from coming to such decisions "after the event." Second, the real problem seems not to be the importance of the event *for fans* but rather that there were perhaps two infringements of sporting *fair play*: with Armstrong and Jones, the actual transgression is compounded by the public lie. And, at least for those adopting an institutional account of sports (McFee 2015b, pp. 57–64), the second is also a sporting transgression – although here against the *spirit of sport* – manifest in one's implicit agreement to abide by this spirit in agreeing to play that sport.

Cheating, Spoiling, and Institutions

Moreover, a standard contrast for fair play is not this kind of (potentially) accidental gaining of competitive advantage, nor the kind of supererogatory action discussed for "racquetless Josie" (above), but rather is *cheating*. And that is the worry in many of the cases of unfair competitive advantage noted above. Literature is replete with interesting discussions of key issues here (see especially, Loland 2002). Still, the contextual character of the issues precludes a simple exceptionless account of cheating and especially one that applies across sports. Thus, one might imagine that all cheating involved the intention to deceive. Many cases fit such a model – tampering with one's épée so that it records hits when none have been scored (Boris Onischenko, in the modern pentathlon in the Olympics of 1976) clearly aims to avoid detection and hence the penalty. The same might be said of so-called diving in soccer, where a player acts as though he has been fouled by an innocent opponent. This kind of deception is akin to *lying*; that in turn suggests what is wrong with it. The gaining of competitive advantage by deception seems to be at the heart of some cases mentioned previously, such as the issues raised by

the allegations concerning Tom Brady's "Deflategate." But is deception always involved in gaining the competitive advantage? Some actions of cheating do not follow this sort of pattern; the "cheater" may have no expectation of the behavior avoiding notice (and the resultant penalty). Indeed, sometimes rule breaking so transparently does not seek to avoid the penalty that one wonders whether it is really best described as *cheating*; for instance, the "professional foul" in soccer where one prevents a goal with a contrary-to-rules action (Loland 2015, p. 344).

Further, we might distinguish, as *spoiling* (McFee 2004, pp. 112–117), actions that give an unfair advantage to one side or one player but are within the rules. There may not be many of these; indeed, they will typically approach varieties of gamesmanship. But they show a different transgression of *fair play*. They typically involve failing to give the opposing team or player a fair opportunity to display his/her skill; eventually what began as such spoiling may become an established tactic used by all teams, as when a master batter is "walked" in baseball by pitching beyond his reach. Here, the fact that all or most teams will employ the strategy restores fairness.

However, such cases – in testing the boundary with cheating – point to another key fact: that, at least for institutionalists of sports (McFee 2015b), the features regularly referred to in attempts to define "sport" do not actually circumscribe sport. Thus, although it is not necessarily a part of some sport (say, cricket) *as such* that its practitioners wear uniforms, it *is* part of that sport as played in certain contexts; in those contexts, there will be rules concerning uniforms – moreover, these will be rules *of cricket*, at least in some sense. Further, consideration of a level playing field explains one reason to investigate the "blades" used by runner Oscar Pistorius for the 2012 Summer Olympic Games: was the advantage thereby gained an *unfair* advantage or simply a leveling of the playing field after his amputations? Similar thoughts also prompt consideration of the technical innovation that Dick Fosbury brought to the high jump at the 1968 Olympic Games: was it a competitive

advantage? It seems clear it was (not least because all high jumpers now use his "flop" technique), but was it therefore unfair? That was the key question; now we know it was accepted. And a part of that acceptance drew on the fact that the technique was in principle open to all. Of course, some diehards at the time might have insisted that it was not "real" high jumping or that it contravened the "real" rules of the sport. But both these suggestions should be set aside. There are no *real* rules, but only the rules of here and now, understood as they are currently understood. So institutionalists recognize that sports may have different features in different contexts. Hence, the idea of "the real sport" should be rejected. Instead, we should be happy that all the occasions on which that sport is played count as instances of that sport (at least when the governing bodies are happy).

Conclusion

Finally, to return to the beginning, the rules of sports are fundamental to discussions of fairness and cheating in the sport and it is important that there are "rules all the way up": rules for changing the rules for playing, rules for changing *those* rules, and so on. The application of those rules, by contrast, is a matter for the informed judgment of sensitive and well-trained judges, such as umpires and referees. They are the ones who must decide whether, say, the gridiron football player was "in control" of the ball when he landed. So these judges recognize transgressions of the rules, as well as accordance with them, and their so recognizing this is typically just what the transgression having occurred amounts to. In that sense, the action of such judges (who will usually be called "referees" or "umpires") resembles what John Searle (2008, p. 49) calls "Declaration," commenting that "[b]y definition, Declarations change reality by representing it as being so changed." So that when the boss says "you are fired," he does not describe the situation whereby I am fired, but *makes it so*. Similarly, the baseball umpire who tells a player, "you're out of here," *makes it so* that the player is out. (And, of course,

such suitably sensitive and suitably informed judges play an even larger role in what David Best called “aesthetic sports.”)

Competitive Education Harms Moral Growth

Jani Pulkki
University of Tampere, Tampere, Finland

Introduction

The growth of a human being has many aspects including morality among its important features. The major traditions of moral philosophy and moral education maintain that morality consists

of cultivating altruism in its different forms such as benevolence, generosity, and friendliness. The opposite of altruism, egoism, is consequently among the key problems of moral education. The human ego is an important phenomena’s of moral education and also key for understanding competitive behavior and motivation. Competition is social action by nature involving at least two subjects trying to outdo each other. The term moral subjectivity refers to individual morality emerging at the crossroad of the individual, cultural, societal, and historical. Competitive human ego is, therefore, constructed as a moral subjectivity by learning language, culture, and ways of interacting in a particular kind of society with a particular history. Egoism is among the hindrances of growing a sound moral subjectivity. This entry describes what harm competition is doing to human moral growth by fostering different features of egoism. Some perennial moral virtues are used in showing this. The benefits of competition are well known and, therefore, left outside the scope of this text.

Competition: The History of an Idea

The word competition derives from Latin “com” and “petere” and was first used in the sixteenth century. Petere means to ask, to seek, and to pursue, and com means this is done with other actors. Often competition is defined as pleading seeking or making a petition together. In economics, it is thought that competition derives from scarcity. When there are not enough resources for everyone, people have to compete against each other for acquiring it. There are problems with this definition as it is not self-evident that all things are resources for human exploit as, for example, parts of nature can be considered holy. Moreover, scarcity is not always absolute, and not all competition is therefore inevitable. Resources can also be shared and allocated with other principles (Polanyi 2001). There is also relative scarcity and a desire to feel superior to other people. This is a competition for scarce resources such as glory, esteem, social standing, and luxury consumption, used for bolstering the human ego.

So, competition is more than mere easy togetherness in making petitions but uneasy struggle for superiority (Nicolls 1989).

In the age of enlightenment and the gradual transition to egalitarian and democratic nation States, competition became to be understood in contrast with the egoistic passions of the feudal nobility and the kings (Hirschman 1982; Elias 1982). Competition, instead of vain and violent glory-seeking passions of the feudal aristocrats, was advocated as calm, peaceful, and rational interaction. Competitive thought emerged out of the need to escape the warring passions of the aristocrats and for enabling a social order based more on democratic principles. Philosophically, the role of liberalism was important in challenging the feudal regime. Freedom, individual rights, and equality without innate privileges were advocated instead of political and economic power transmitted within family relations. Competition became to be understood as a vehicle of predictable, transparent, and peaceful self-interest rather than mere aggressive passions (Elias 1982; Hirschman 1982.)

Altruism and Egoism in Human Nature and Culture: Bewildered Moral Subjectivity

There remains continuing bafflement about how competition is understood in using two of the most basic moral categories (Fromm 1986; Horney 1964; Hirschman 1982): On the one hand, it is presumed that there is (1) unpredictable and unstable emotional passions, self-sacrificing altruism, and love for others. On the other hand, there is (2) rational and stable interests with self-love and rational egoism on the basis of competition. In other words, moral subjectivity is disoriented in holding simultaneously that (1) self-love is morally wrong and love for others is morally right and (2) pursuing one's own self-interest with greed and selfishness in competition is advantageous for the economy (Fromm 1986, p. 33).

In terms of modern psychology, the old opposition of passions and interests is misleading, and according to Erich Fromm, altruism and egoism

are not contradictory or alternative concepts (1986). Competition of supposedly value-neutral interests, instead, socializes and teaches also passionately selfish behavior, not only calm pursuit of sustenance. This learning is usually disregarded for selfishness and greed are now accepted motives for economic activity. There have been few notable and outspoken theorists such as neo-liberal thinker Friedrich von Hayek favoring competition for its moral desirability. The controversy of private vices and their public benefits has been ongoing since Bernard de Mandeville (1670–1733) and Adam Smith (1723–1790), who is considered the father of modern economics. In economics, competition today is assumed as the most desirable form of social interaction. This is not usually questioned, but competitiveness, selfishness, and greed are considered as universal traits of human nature (Marglin 2009). Instead of a direct endorsement of competition, individual rights, freedom, and equality are commonly stressed thus resulting in competition.

One solution widely in use for the uneasy coexistence of opposing moral traditions of altruism and egoism has been separating the realms of (1) moral and political matters and values from (2) nonmoral, economic, and value-free matters. Using this separation of the value-laden political and the value-free economical (Polanyi 2001), moral ambiguities about egoism, greed, and pursuit for superiority are disregarded. Human wants and needs are seen insatiable in mainstream economics, so scarcity and competition that necessarily follow (Marglin 2009). The possibility of allocating resources outside competition, as done in most of human history (Polanyi 2001), is disregarded as economically inefficient and restrictive for individual freedom.

Karl Polanyi (1886–1964) has demonstrated that the separation of political and economic realms is a historical, cultural, and ideological separation, not an inevitable one (2001). The idea of competitive human nature ignores the phenomena of learning, and in anthropology, there remains little question that competition is, to a large extent, a result of history, culture, socialization, and learning (Montagu 1952). The disorientation about the role of altruistic and egoistic

motives has remained, however, a constitutive feature of contemporary moral subjectivity. Human being is seriously blocked in integrating one's personality as this moral predicament remains unsolved (Horney 1964; Fromm 1986, p. 127). In a state of bewilderment and helplessness, cultivating morality is difficult as the question of what is cultivated remains unclear.

Meritocratic Frustrations and Challenges to Moral Subjectivity

Democratic societies allocate resources according to merit, and people are assumed free and equal in participating in competitions. The capability approach to human freedom and justice by Amartya Sen and Martha Nussbaum has demonstrated, however, that formal freedom in terms of law does not guarantee equal starting points for life. Giving legal freedom to all does not mean everyone have the same possibilities and opportunities for success. The Sociology of Pierre Bourdieu (1930–2002) has further demonstrated how social, cultural, and economic capital is an object of reproduction and inheritance. Human capabilities are, to a large extent, inherited through upbringing, education, and socialization. “Accidents of birth” work in both nature and nurture in affecting our possibilities to compete successfully. The welfare State model and socially oriented liberalism include active educational measures and social policy for compensating these accidents of birth.

Neoliberal influences of the late twentieth century and the beginning of the twentieth-first century have made it increasingly challenging to develop a well-proportioned moral subjectivity. The belief in the fairness of competition, and thus democracy, has eroded with the “winner-take-all” reward structure in which the remuneration schemes of an elite and the majority are increasingly separated. Neoliberal ideology of free competition, unfettered markets, and minimum state with little or no compensation for the “accidents of birth” gives rise to discontent as inequality is seen economically stimulating and desirable. When considering together the winner-

take-all resource allocation scheme, the meritocratic-individualist concept of human being, the virtue of strong will, and the increased acceptance of inequality, it can be noticed how harms to moral growth emerge. While trying harder is a sound pedagogical advice to some situations, the inherent logic of competition does not enable success for everyone. Having a strong will does not change the fact that competitions produce more losers than winners.

Emphasizing strong will means overdeveloping the will at the expense of the intellect and senses. The intellect, senses, and emotions are developed for the purpose of success and for boosting the ego. This is not conclusive to moral growth. For example, learning empathy is hindered in competitions as the suffering of the loser is deemed solely one's own fault in failures of effort, will, and skill. This way empathy is crowded out and replaced with harsh attitudes accompanied by unfriendly blame and unwillingness in understanding all the effecting factors behind the defeat. A strong will, unable to achieve success, gets easily frustrated as competitions are taken as an empiric and objective truths of people's abilities. An experience of failure, taken as an objective evidence of the personal inadequacies, can be unbearable. A strong will, frustrated in defeats, can externalize its frustrated psychological energy to aggression and intolerance toward those deemed inferior. Thomas Hobbes (1588–1679) already noticed that competitive pursuit for superiority is among the causes of violence and war. As the victors have proved their superiority by their success, they often avoid the disgruntled blame, which is channeled, for example, to ethnic or cultural intolerance without coming in terms the societal and economic reasons behind the disappointment.

Competitive Education and Moral Harm

Contemporary dominant narrative of good life in the twenty-first century consists of success in competitions. In containing value judgments about people superiorized and inferiorized, competition is not only a value-neutral matter. Nor it is

solely a matter of economic necessity or sustenance. As an organizing and justificatory principle, competition is a fairly recent development, which has been mostly absent in playing a major role in world economic history (Polanyi 2001). This has changed during the last two hundred years. In the twenty-first century, competition is the cornerstone of current belief system confined not only in the economy. Instead, competition radiates into all other activities and permeates love, social relations, and play also (Horney 1964, p. 188). For example, competitive sports and success have been a central part of the twenty-first century narrative of good life, and they were introduced in schools in the nineteenth-century imperial Great Britain. Sports have been taken on for building characters and national identities and, for example, military performance. Sports and other kinds of competition do include aspects of character building but a lot of unfounded beliefs and misunderstandings also.

In terms of moral development, competitions have the effect of hardening the moral subjectivity. Abstaining from helping and hindering the learning of helping are examples of this. Hardening of moral subjectivity is, however, often welcomed as a mark of strong will and capability for relentless effort and the go-getter attitude. In this case, however, the world “tough” preferred. Especially in masculine contexts, this is an adjective by which the highest respects are paid. The distance of meaning between terms such as hardened, callous, and tough can be explained by the heroic imagery attached to winning. The mixed attitudes toward hardening and toughness explain why one key harm competition is doing to moral growth is often left unattended:

Recognition and loving approval are made artificially scarce resources, an object of competition, even though everyone is in need of these. Love is a key phenomenon in becoming human being and a moral subject. Making children compete for approval hinders the growing of healthy sense of self-worth and self-respect with compassion to one self as well as to others. Everyone is as good as their latest performances, and people are judged by their competitive success. People are thus left in fear of poor judgments (Nicolls 1989).

On the other hand, love and affection regardless of merit make a person more durable in cases of traumatic experiences such as of losses accompanied by humiliation (Horney 1964, pp. 80, 211). Loving approval protects children from the harmful effects of competition and also fosters competitive success in supporting the growth of balance personalities. Denying loving recognition and affection through competition produce insecurity sometimes accompanied by neurosis and pride (Horney 1964). Loving care is the key for basic security and self-esteem.

Pride, instead, is a substitute for healthy sense of self-worth and self-respect but a poor one as it fluctuates in changing social comparisons. Instead of a deep introspection conducive to moral growth, competition turns the attention of a person outside, to superficiality of extrospection. The concept of *Das Man* or “the They” by Martin Heidegger (1889–1976) describes this kind of human being whose existence is characterized by impersonal, unspecified, and inauthentic attributes. Instead of an authentic self, the *das Man* competitor values and thinks what is generally valued and thought. This way, competition socializes people to believing that the same yardsticks for success and good life apply for all resulting in relatively homogenous system of beliefs. This system of belief fosters, unintentionally, also envy as people are inadequately encouraged to find their own authentic sources of happiness. Envy is wanting what the others have and the repulsive feeling accompanied. One reason for envy is the unrecognition of one’s existential needs, which make people want what the others have instead. Other reason for envy is the failure in recognizing the ontological difference of needs and wants in economics, which makes people endeavoring also things that do not make them genuinely content. Envy is in fact included in many practical moral problems such as conspicuous consumption (Veblen 2008). Another example is the case of envious malice accompanied by wicked joy in witnessing a failure of another person.

Competitive concept of human being consists of autonomous and self-interested people relying solely on their own performance. It is not wicked

joy or envy but the interest of the self, a rational self-interest, to deny help from others in competition. Helping others decrease one's relative standing, so it is not considered rational for the individual. Giving help is a form of altruism, and not granting help is related to egoism at least when this is not overwhelmingly demanding. Generosity is another form of altruism related to helping, and it can be defined as a propensity for kindness and friendliness and willingness to give and share one's own. Competition means acquiring more resources like social recognition, esteem, money, and respect to oneself rather than giving it away. Group competition is a different matter as help and generosity toward one's own group are encouraged.

Failures of learning empathy, generosity, helping, and mutual joy from the accomplishments of others are among the features of hardening the moral subjectivity in using competition in education. And competition, when it is practiced in society and economy, has also educative effect in socializing people to certain ways of thinking, feeling, and wanting. Hardening of moral subject means the suffering of people and destruction of nature and its living beings are disregarded, naturalized, and normalized. Moral insensitivity is crowded in, and toughness is celebrated even with its dire effect on the moral growth.

Concluding Remarks

Competition involves both benefits and harms to moral growth, and the benefits are typically exaggerated. What is known as character building is, for example, often erosive to the moral growth in hardening the moral subjectivity for competitive success. Moral education and moral growth consist of learning and teaching critical moral reasoning, good will, and moral sentiments in well-proportioned relations with each other. Inasmuch as competition is developing the will at the expense of the intellect and moral emotions, a well-proportioned human moral growth is considerably harmed. For moral growth it is more advisable to use collaborative teaching environments to

fostering friendliness, sharing, trust, and mutual help. Insofar as competition becomes an all-encompassing feature of social life, people are in fear of other people taking what is theirs. So, they learn to mistrust and fear each other. This is not conducive for learning friendly sharing, trusting, generosity, and mutual help. Avoiding competition and favoring collaborative teaching are not only morally but pedagogical grounded (Johnson and Johnson 1989).

Conceptual Change in Science and Science Education

Ross Nehm¹ and Kostas Kampourakis²

¹Stony Brook University, Stony Brook, NY, USA

²University of Geneva, Geneva, Switzerland

Introduction

A large body of work in science education and conceptual development research has noted that historical changes in scientific ideas display similarities to students' conceptual progressions along a novice-expert continuum. For example, researchers have noted that scientists' historical resistance to changing their pre-Newtonian ideas relating to mechanics was very similar to modern students' difficulties abandoning pre-Newtonian ideas, that there are parallels between students' ideas of chemical equilibrium and earlier scientists' conceptual models, or that students' thinking about evolution appears to parallel large-scale changes in scientific thought from essentialist to selection-based views of evolution. In contrast, other scholars have cautioned that purported similarities between students' conceptual changes and the historical development of scientific concepts are superficial and are derived from different methods and sources of knowledge (Nersessian 1989). Students' conceptions of heat and

temperature, photosynthesis, the shape of the Earth, and natural selection, for example, have all been noted to display significant discordances relative to patterns of historical development. Nersessian (1989) in particular has warned that metaphysical, epistemological, and sociological factors make comparisons between modern students' learning patterns and historical changes of scientific concepts problematic. However, it is also clear that different scientific concepts from different domains may display different degrees of cognitive-historical parallelisms and exhibit unique features that prohibit broad claims that cut across scientific disciplines, historical episodes, or cultural contexts (Ha and Nehm 2014). Therefore, the unsettled question is how the history and philosophy of science (HPS) can appropriately inform science education research and practice – specifically, research and practice relevant to conceptual change.

Conceptual Change in Science Education and in the History of Science

The topic of biological evolution serves as a useful case study for exploring putative parallelisms between conceptual change in students and the history of science (HOS). The science education and conceptual development literatures have suggested that there is a striking similarity between (1) a paradigm shift from “Lamarckian” or essentialist, pre-Darwinian views to “Darwinian” or selection-based views of evolution and (2) students' conceptual progressions from naïve to normative evolutionary understanding (see Kampourakis and Nehm 2014). Detailed empirical studies informed by HOS have raised questions about these purported parallelisms between historical change and student conceptual change. For example, students' conceptions prior to formal teaching have been found to be mostly teleological, whereas the core of Lamarck's thinking was not (Kampourakis and Zogza 2007). These empirical studies have questioned the assumed correspondence of (a) students' pre-instructional views with

Conceptual Change in Science and Science Education, Fig. 1 Illustration of the composition, structure, and coherence of student ideas

pre-Darwinian ideas and (b) students' post-instructional views with Darwinian ideas.

Given that students' conceptions only superficially resemble those of historical figures, it is not clear what is gained by labeling particular knowledge elements or conceptions with particular historical figures. Moreover, accurately linking historical figures to particular scientific concepts is not straightforward. Contrary to popular wisdom, Darwin embraced several ideas characteristic of Lamarck (e.g., use and disuse inheritance). In some sense, Darwin was perhaps more "Lamarckian" than Lamarck himself, as he accepted that the direct influence of the environment could produce variation (Burkhardt 2013; Ha and Nehm 2014).

In addition to empirical studies calling into question the parallelisms between conceptual change in science and science education and the difficulty of ascribing particular ideas to particular historical figures, Gault (1991) emphasized differences in the way that understanding is achieved in students and scientists. He noted that (1) the intuitive development of students' ideas is a different process from the conscious theory construction of a scientist and (2) students' conceptions are often developed privately and are based on everyday experience, whereas scientists' ideas are often developed in consultation and confrontation within the scientific community and are built upon empirical evidence gathered in systematic ways. For these reasons, comparing students' individual conceptual changes with large-scale paradigm shifts is not really informative.

Conceptual Composition, Structure, and Coherence: The Foundations of Conceptual Change

In order to better understand conceptual change, for several decades, science educators have empirically explored the question of whether students' conceptions about a variety of science topics display stability or coherence. On the one hand, student ideas have been conceptualized as dynamic, fragmented, and highly situated and, on the other, as stable and relatively consistent across contexts (see chapters in Vosniadou 2013). A large amount of evidence has been gathered to explore and test these perspectives, although differing interpretations of this evidence have occurred in part due to the complexity of extracting information from students and the different methodological approaches that may be used to analyze student conceptions.

The apparent diversity of student conceptions has implications for research on conceptual change. Conceptual change could involve changes in the composition of conceptions, in the structure of the same (or different) conceptions, and/or in the consistency of the use of conceptions across different problem types or across the same types within different contexts (Fig. 1). It could also involve the change in the hierarchical status of different knowledge elements in different situations.

The categorization of student conceptions may be organized in many different ways, complicating characterizations of conceptual change. Conceptions may be described as scientifically normative

(e.g., mutation as a cause of phenotypic differences) or nonnormative ideas (e.g., use-disuse inheritance). Nonnormative ideas can be further categorized into “cognitive biases” (e.g., psychological essentialism, design teleology) versus “other ideas” (e.g., use inheritance). Additional taxonomies based on cognitive composition are possible as well as taxonomies that situate ideas within deeper theoretical frames. The broader point is that the composition of student conceptions is remarkably diverse and that comprehensively capturing and classifying the diversity of ideas that a student harbors is not straightforward at all. Overall, conceptual change research often lacks comprehensive descriptions of the full diversity of student conceptions, and categorizations of these conceptions are constrained by theoretical frames of reference. Assessment of the diversity of conceptions and categorization of conceptions are needed to estimate the type and magnitude of conceptual change.

Conceptual change from a purely naïve to a purely scientific composition appears to be uncommon. In the largest empirical studies of student conceptions to date ($n > 10,000$), the majority of students built the so-called “mixed” or “synthetic” models of evolutionary change (Moharreri et al. 2014). For example, a student may combine the idea of teleology with the ideas of mutation and heredity to build a mixed model (e.g., “The plants needed a mutation in order to survive and so they developed new traits that were passed down from generation to generation”). This is important to note, as instruction aiming at conceptual change will most likely have to consider a variety of mixed conceptions as possible targets. It also suggests that categorical measures of conceptual change (naïve vs. normative) are too crude and will not elicit particular conceptual ideas during instruction.

In addition to considering the composition and structure of student conceptions, research has begun to explore the contextual nature of conceptual change and its implications for cognitive coherence (Fig. 1). Although the general idea of the situated or contextual nature of evolutionary thought was mentioned in the literature decades ago, robust empirical studies were not conducted

until more recently. The empirical work of Kampourakis and Zogza (2009) provided insights into the incoherence of evolutionary thinking, but it did not systematically control for task language and problem structure when characterizing coherence. In contrast, more recent empirical work controlling for task language, problem type, and problem features has confirmed prior work and shown that novice (e.g., secondary and university student) ideas about evolutionary change lack coherence across contexts (i.e., different knowledge elements are arranged into different structures in different scenarios).

Using such “controlled” experimental designs, generalizations about the contextuality of novice evolutionary thinking are emerging. Reasoning about evolution has been found to be (1) *lineage dependent* (e.g., plants vs. animals), (2) *polarity dependent* (e.g., gain vs. loss of a trait), (3) *familiarity dependent* (penguin vs. prosimian), and (4) *scale dependent* (within vs. between species; Nehm and Ha 2011). Evolution experts, in contrast, when answering items, *within a problem type* (e.g., a natural selection question), demonstrate coherence or consistency of ideas *across* contexts. These more fine-grained characterizations of student thinking help to illustrate the diversity of ways in which conceptual change may be described. For example, conceptual change may be achieved in relation to *scale* but not in terms of *polarity*. Thus, the context in which change is examined becomes central to studies of conceptual change.

Collectively, empirical studies of the composition, structure, and coherence of student ideas within and across problem types and contexts raise important questions about what we actually know about what changes in students’ ideas about evolution and which changes should “count” as conceptual change. Regardless of conceptual scale, several studies demonstrate that student understanding of evolutionary change lacks “coherence” in a general sense. In other words, educational interventions that change the composition and structure of student ideas relating to the evolution of trait gain in an animal lineage might not change the composition and structure of student ideas relating to the evolution of trait loss in a

plant lineage. Has conceptual change occurred in the animal case but not the plant case or has conceptual change not occurred at all because a coherent model has not been used in *both* contexts?

Our review of some of the empirical considerations relating to the study of conceptual change highlights a lack of precision in the documentation and characterization of change. Additional empirical work that takes stock of the composition, structure, and coherence of student ideas within and among problem types will be needed in order to address these questions. In summary, situating student ideas within the composition-structure-coherence framework might help to standardize empirical studies of conceptual change. It also might serve as a useful framework for looking at HOS and its relationship to conceptual change.

The Coherence of Scientific Conceptions: Disciplines and Individuals

In the previous section, we identified an important lacuna in conceptual change research: there is little empirical research on whether students' conceptions and explanations about evolution are coherent or not, as well as on their more detailed compositions and structures in different scenarios. This seems to imply that the goal of teaching for conceptual change in evolution is to build a robust and coherent conception of evolution across contexts. However, coherence is not necessarily a characteristic of past scientists. As noted by diSessa (2014), Toulmin provides a counterpoint to Kuhn's model of scientific paradigms and paradigm shifts, which has in turn served as a template for science educators' views about conceptual change.

Kuhn suggested that scientific advancement was characterized by a series of periods of "normal science" punctuated by intellectually violent revolutions in which particular conceptual worldviews, the paradigms, were replaced. According to Kuhn, scientific revolutions occurred when anomalies emerged that could not be explained by the accepted paradigm,

which was eventually replaced by a new one. This change from an old paradigm to a new one was described as a "paradigm shift," and it happened all at once, like a gestalt switch, but not necessarily in an instant. Toulmin criticized this, and the underlying assumption that paradigms are coherent wholes, by pointing out that different concepts and theories are introduced into a scientific discipline at different times and for different purposes, independently from one another. Therefore, a scientific discipline is more like a "historical population of logically independent concepts and theories" rather than a "single logical system with a single scientific purpose."

Conclusions: Cognition and Scales of Comparison in Science Education Studies

We argue that it is problematic to describe students' ideas using labels that align with large-scale changes (paradigm shifts) in the HOS. Darwin and Lamarck, for example, each possessed very detailed understandings of organisms' structures and physiologies and proposed equally detailed explanations for natural phenomena. The "funds of knowledge" that these naturalists possessed and used to create understanding were very different in form and quantity with those of modern-day students. These historical figures pieced together new models of understanding, whereas many students of today are adopting models developed by others (as part of formal or informal learning opportunities). Unlike the ideas of Lamarck and Darwin, modern-day students' ideas about evolutionary change appear to be much less coherent; large numbers of students have been shown to display diverse assemblages of concepts (normative and non-normative) deployed in diverse combinations depending on the living systems that they are asked to think about (Nehm and Ha 2011). Unless singular, robust cognitive models characterize student thinking, it is difficult to argue that their models are "Lamarckian" or "Darwinian," for example.

However, labels notwithstanding, studying the thought processes of individual scientists of the past can be very instructive. Studies of the cognitive processes of past scientists suggests that novel concepts do not emerge fully formed in the minds of scientists, but they rather are the products of lengthy and intentional cognitive activity (Nersessian 2008, p. 5). It is the latter that may be informative for science educators. If the goal is to identify students' conceptual obstacles and develop teaching approaches that will help them overcome these obstacles, then it would be most fruitful to examine the conceptual challenges that individual naturalists/scientists had to face rather than examining simplified paradigm shifts characteristic of many scientists over large time spans. This approach does not guarantee any positive outcomes, because eventually the conceptual challenges faced by students and past scientists may be different. Yet, if there really is a role for HOS in conceptual change research, it should be in making comparisons at the individual level: the challenges faced by individual scientists in the past may help researchers better understand the challenges that individual students currently face.

Configuration

► Configured Leadership

Configured Leadership

Peter Gronn

University of Cambridge, Cambridge, UK

Synonyms

Collective; Configuration; Hybrid; Leadership; Shared

Introduction

To inquire of a phenomenon how it is configured or set up is to investigate its properties and the dynamics of their operation. Because in the case of leadership the persisting orthodoxy that there is

a leader and a plurality of followers is so deeply culturally entrenched, such an inquiry risks being dismissed as either superfluous or pointless. But what if it could be shown that there exists a plurality of leaders, so that leadership is a kind of moveable feast that migrates between individuals? This was roughly the point of recognition at which the Australian social psychologist, Cecil Gibb, arrived in the mid 1950s. Gibb's (1954) realization about plurality prompted him to distinguish between a leadership relationship that was focused on just one individual as the leader and a relationship in which leadership was distributed among a number of individuals, with the validity of the claim to being a leader grounded in his view derived from the measurements of a third party observer (or researcher) – and for later commentators (especially attribution psychologists) was grounded in the perceptions of those who were participants in the relationship. Regardless of whether normatively Gibb's distinction is viewed favorably or unfavorably, in the six decades since he published the popularity of distributed leadership, particularly in the education sector, spiked dramatically during the 2000s – as was demonstrated by Bolden's (2011) analysis of its recognition and uptake.

But suppose that the understanding arrived at by Gibb is complicated a little further. If he was right about leadership being constantly on the move, then a consequence of that migratory feature may not only be the need for a rethink about leaders but also the threatened redundancy of followers as a category. That is, if everyone might become a leader (potentially), then there is no need to have followers. To complicate matters even further, what if it could be shown in the case of this shifting array of leaders that at least some of the subjects attributed with leadership are not merely atomized individuals but also pluralities (i.e., groupings in which $N = 2$ or $2+$): where might that possibility leave the conventional and time-honored leader-follower linguistic and representational binary? This acknowledgement of plurality expresses the contemporary position presently attained by the leadership field generally and the educational leadership subfield specifically. To be able to accommodate within a revised

unit of leadership analysis varying combinations of individuals and pluralities, however – and to avoid the error of jettisoning individuals altogether by merely substituting Gibb's distributed leadership for his focused category—requires for the representation of such an ontology a more expansive term than distribution. That term is configuration.

Unit of Analysis

This claim that the unit of leadership analysis is configured need not entail the advancement of a normative commitment about the desirability or otherwise of particular configurations, but is to prioritize the contouring of the realities of leadership's practice. Moreover, to have in mind the charting of the structural and operational details of a range of leader configurations also need not commit a researcher to an epistemological claim about the existence of a distinctive and bounded form of knowledge that can be labeled "leadership." Nor does the assumption follow that leaders lack knowledge because persons who occupy a range of roles that carry with them expectations of leadership, including positions of headship, and who may embody the leadership attributions of their peers, are known to acquire working knowledge and in some instances to accumulate such knowledge to a level of cognitive codification sufficient to realize a range of capabilities. Finally, the idea of a configuration trades on one further distinction about leadership made by Gibb who, when querying its scientific value as a category, recognized its continued popularity and utility as a descriptive term in everyday usage. That is, there exists a framework of expectations of leaders and leadership (which is to some extent implicit, to some extent explicit) within the consciousness of people who inhabit a range of social formations, and who act purposefully within a variety of settings, along with an attendant willingness on their part to attribute the status of leader and the embodiment of leadership to a person or persons, grouping or groupings (for an extensive range of instances of the latter see Denis et al. 2012). If this line of reasoning is valid, then it makes sense to

research real-world exemplars (contemporary and historic) of persons and groupings that have attained leader or ruler status, with a view to ascertaining how and why within various frameworks of expectations leadership operates as it does, to track its accomplishments or lack of accomplishments, and to identify its consequences (intended and unintended).

The upshot of the foregoing discussion, then, is that a leadership configuration is a short-hand term for an objectively understood patterning or arrangement of dynamic parts that integrate to some degree to constitute an evolving whole, with such leadership wholes comprising hybrid combinations of persons and/or smallish number groupings that get to be acknowledged as leaders. Illustrations of configured leadership in spheres such as education are manifold (see the examples cited in Gronn 2011, pp. 442–444). In contexts in which individuals share a leadership space, their coordinated relationship may be institutionalized or may emerge informally Gronn 2015. An instance of the former is co-leadership, such as a deliberately designed school co-principalship, while in the latter a typical illustration is informal, unplanned temporary partnering (for, say, the duration of a project) such as between a principal and teacher colleagues who possesses specialist expertise relevant to the resolution of problems. To complicate a little further this picture of fluid practice, individuals in headship roles (such as the principalship) have been shown during the workflow to sometimes to act alone, while on other occasions they partner and on still others they operate as members of small groupings. In all expressions of both formal and informal co-leadership, this shared division of labor gives expression to a sense of conjoint agency. An advantage of such a labor division is that it permits capability pooling. That is, role robustness is made possible by the expression of differentiated although complementary specialist skills along with a duplication of skill-sets that facilitates person substitutability. Equally, what might appear to be unnecessary role redundancy (i.e., skill overlap) may in fact turn out to be a virtuous unintended consequence in that such redundancy affords a reduction in the organizational risk

exposure that might result from the temporary absence or loss of key personnel. These possibilities facilitated by a joint leadership role space occupied by at least two persons are also evident in the case of small number groupings of three, four, or even five members, with a membership size of six being the numerical ceiling beyond which the likelihood of efficient group self-organization diminishes (Gronn 2010). Everyday terms such as teams or teaming are often used to designate these $N = 2+$ units.

Evidence of such leadership hybridity, however, is by no means restricted to contemporary social formations. Accumulating data on rulership in small-scale pre-nation State and pre-kingship societies, for example, highlights the coexistence (in a number of instances) of individual chiefdoms and conciliar institutions, along with rulership regimes in which both of these types alternated over time and through many generations of leaders. In the evolution of increased complexity in societies and polities, a growing number of scholars in the disciplines of anthropology and archaeology have detected alternating or coexisting pressures of egalitarianism and stratification in social orders in which contrasting strategies of personalized power and corporate power contended, and to varying degrees became institutionalized. In hunter-gatherer foraging bands, for example, the group pressures towards the suppression of alpha-type individual band members (through a disciplining process known as reverse dominance hierarchy), along with shirking and free-riding behavior by feral individuals, ensured that hierarchical impulses were trumped by egalitarian norms. Individual leadership may have been tolerated informally but only to the extent that it was required for functional purposes (e.g., group protection and skills dependence in big game hunting). The factor that eventually strengthened the likely emergence of hierarchy was cognitive evolution in brain morphology: this development permitted human perspective-taking, along with status and role differentiation and ascription to key individuals, and also, as group memberships increased in size, relief from the constant monitoring of individuals and their behavior, that was facilitated by the

institutionalization of a division of social sanction (Gronn 2016). Provided that future research outcomes in these two scholarly disciplines confirm this trajectory of knowledge, then there is clear longitudinal evidence of historical continuity with respect to a norm of leadership being configured in a hybridized form.

Research Questions

The preceding analysis gives rise to a number of points of research significance in respect of leadership configurations. The first concerns the universe of empirical possibilities. A key question here is: to what extent is the range of types and numbers of leadership configurations likely to be so divergent that these are potentially infinite or can they be shown to narrow around a convergent mean that encompasses a small range of preferred types? If the answer lies in the latter direction, why might that be? What factors, for example, in the decision-making realms within which leaders typically operate, select for such purposes as utility and efficiency certain configurational options and reject others (a phenomenon that is sometimes referred to as environmental fit)? It is surely noteworthy (and also well documented) that for an extended period of time school principals, particularly in England, have been adopting the practice of assembling small cohorts of colleagues, labeled variously senior leadership or management teams, in recognition of the fact that the pedagogical and curriculum information spaces within which they operate are increasingly vast and so never-endingly expanding that they defy monopoly control and processing by one (leader) brain alone. A second and closely allied area of research interest is the connection between configurations and organizational outcomes. Causal links between structural and processual relations and their effects tend to be notoriously difficult to measure, but if in the interests of the effectiveness of workflow operations it might be shown, for example, that within a converging range of configurational leadership types certain options provide a more likely guarantee of economy of workplace energy, then such knowledge offers a firm

foundation for choice. A third point of significance concerns the implications for the recruitment, selection, and development of leaders who may be required to function in shared role space configurational arrangements that simultaneously require solo, partnering, and team operations. Here, capability frameworks assume importance. Existing leadership capability frameworks tend to vary in the degree to which they are framed normatively around statements of performance desirability and the extent to which they draw on an evidence-base grounded in the documented realities of practice. If such frameworks are to remain credible, as the pressures for the professional recognition of leaders' accomplishments build in favor of research-based performance standards, then they will need to articulate both individual and collective leadership capabilities. Currently in the leadership field, however, compilation of the evidence-base in respect of knowledge of the former, let alone the latter, remains in its infancy.

Unfinished Business

The final point about the wider significance of leader configurations is to do with continued inertia or resistance to the possibility of leadership plurality, notwithstanding the recent developments summarized above, and the iron-like grip that common sense understandings have concerning the individual agency of leaders. In political science, for example, Brown (2014) has attacked the dominance of so-called strong leadership and its attribution to individual heads of government, in both democracies and authoritarian States, as not only exaggerated, but as lacking a factual basis and therefore as illusory. Moreover, "far more desirable than the model of the political leader as master," from a normative perspective, "is *collective leadership*" (Brown 2014, p. 3, original emphasis). Leadership biographers may be complicit in the fostering of such misperceptions, and yet when examined closely biographies manifest evidence of leadership spaces that are simultaneously occupied by a number of key players. The problem here is partly a failure or an unwillingness to confront issues concerned with

leadership ontology (such as those considered above) and partly the discursive misrepresentation of ontological realities arising from a dependence on traditional leadership language. Roberts' (2014) recent biography of Napoleon Bonaparte – which, with its title, *Napoleon the Great*, appears at face value to be a study in the great man leader tradition – illustrates how even in studies of dictators (extreme instances of Gibb's focused leaders) multiple leadership, although not explicitly acknowledged as such, plays a central role. Here, to take but one instance, is an unequivocal illustration of what I instanced earlier as partnering (Roberts 2014, p. 80):

Napoleon was the first commander to employ a chief-of-staff in its modern sense, and he couldn't have chosen a more efficient one. With a memory second only to his own, [Alexandre] Berthier could keep his head clear after twelve hours of taking dictation; on one occasion in 1809 he was summoned no fewer than seventeen times in a single night. The Archives Nationales, Bibliothèque Nationale and the Archives of the Grande Armée at Vincennes teem with orders in the neat secretarial script and short concise sentences that Berthier used to communicate with his colleagues, conveying Napoleon's wishes in polite but firm terms, invariably starting 'The Emperor requests, general, that on receipt of this order you will. . .'

And here is how the Bonaparte–Berthier partnership and the collective leadership machinery headed up by Berthier gave it practical expression (Roberts 2014, p. 81):

He [Berthier] rarely opposed Napoleon's ideas directly except on strict logistical grounds, and built up a team that ensured the commander-in-chief's wishes were quickly put into action. His special ability, amounting to something approaching genius, was to translate the sketchiest of general commands into precise written orders for every demi-brigade. Staff work was rarely less than superbly efficient. To process Napoleon's rapid-fire orders required a skilled team of clerks, orderlies, adjutants and aides-de-camp, and a very advanced filing system, and he often worked through the night. On one of the few occasions when Napoleon spotted an error in the troop numbers for a demi-brigade, he wrote to correct Berthier, adding: 'I read these position statements with as much relish as a novel.'

By contrast, in another recent analysis of a dictatorial regime – Fitzpatrick's (2015) account

of Joseph Stalin in *On Stalin's Team* – collective leadership is not only documented in extensive detail, but its (ontological) significance is explicitly acknowledged. In the wake of the importance attached to such collective leadership by the then recently deceased V.I. Lenin, the team of about a dozen men formed in the 1920s by Stalin persisted until a few years after his death (1953) before it disbanded. As a collective entity that met regularly as a group its members exercised individual responsibilities, and were united in their loyalty to Stalin and to one another. Analogous to a sporting team, Fitzpatrick characterizes Stalin as captain and playing coach. While he defined the team, and its practice was to attribute “all initiative” to Stalin, it continued (unexpectedly) to function as a team without him following his death, having worked around him in the lead-up period of his mental decline and eventual demise (Fitzpatrick 2015, p. 2, original emphasis). Team members acted throughout the period with varying independence in their spheres and were conscious of themselves as being part of a collective unit (as well as being individual rivals), and whenever Stalin sensed that backing for what he wanted to do was “lacking or lukewarm,” he retreated (Fitzpatrick 2015, p. 3). Notwithstanding these collective dynamics, earlier Stalin and Soviet scholars had mostly focused on “the man alone, emphasizing his charisma, cult, and omnipotence,” and had disregarded or played down the activities of official (State and party) institutions. What changed that perceptual misattribution was the opening of the Russian archives in the 1990s, following which “previously invisible aspects of the political process came into sight, and scholars' interests started to shift to the relationships of Stalin and the men around him, variously referred to as his ‘entourage’ or the ‘inner circle’” (Fitzpatrick 2015, p. 271).

Conclusion

With leadership continuing to be taken seriously by scholarly and nonscholarly audiences alike, these two powerful examples along with the earlier summaries of developments in the field's

literature highlight the need to accord closer attention to the unit of analysis than previously has occurred, and how leadership is, and comes to be, configured in the particular ways that it is. Taken together, scaled down expectations of individual leaders along with an increased recognition of pluralities and collective units promise not only to inject into leadership a welcome note of realism but also an informed awareness of the complexities entailed when humans strive cooperatively to achieve coordinated plans, an outcome which, surely, offers a potential win-win for everyone concerned.

Synonyms

Confucian; Culture; School leadership; Values; Vietnam

Introduction

School leaders in contemporary Vietnam are affected by a number of forces, including globalization and integration, changing government policy, and Western-centric ideas about democratic leadership, in addition to traditional cultural influences. Of these forces, *traditional values* are believed to exert the strongest influence on school leadership. This chapter discussed how Vietnamese school leadership is influenced and shaped by traditional Confucian values. Although the imprint of Chinese civilization and Confucian thought has waned in recent years, the core values of Confucianism remain deeply rooted in Vietnamese society, influencing the country's philosophy, culture, society, economy, and politics (Ashwill and Diep 2005; Jamieson 1993). These traditional values in fact constitute the underpinnings of Vietnamese culture. Jamieson (1993) used two words to describe Vietnamese culture in modern times: “change” and “continuity.” Change refers to the process of accepting and developing new cultural values imported into Vietnamese society, whereas continuity is the process of preserving and maintaining Confucian-inflected traditional values. Confucian values continue to exert a powerful influence:

For more than two thousand years, Confucianism has existed in China and in our society [Vietnamese society] without changing, and thus from the past to

now, all through society, not only the ranks of Confucian scholars, but the common people as well became imbued with the Confucian spirit. We can say that throughout one's life, whether in Chinese society or in Vietnamese society, one breathed a Confucian atmosphere, fed on the milk of Confucianism, ate Confucianism, and even died with Confucian rites. From thought, language, and the actions of individuals to learning and the social system, nothing escaped the control of Confucian philosophy and ritual teaching. ("Dao Duy Anh," as cited in McHale 2002, p. 422)

In today's Vietnam, although a number of forces are imposing tensions on school leadership, among them such processes of modernization as a globalizing policy environment and the need to move from a highly centralized to a decentralized system of educational management (Walker and Dimmock 2002), Confucian values remain a potent force in leadership practice. The aim of this entry is to describe the basic Confucian values at work in contemporary Vietnamese society and the way in which those values influence school leadership practice. It considers the way in which educational leaders exercise power within schools and the leadership styles they adopt within the influential discourse of traditional Confucian values.

Confucianism in Vietnam

Confucianism can be defined as a worldview, an ethical system, a political ideology, and a scholarly tradition developed from the teachings of the ancient Chinese philosopher Confucius. Confucianism conceives of the individual not as a detached entity, but as part and parcel of a series of human relationships (Goldin 2011). Fulfilling one's roles within these relationships is considered essential to creating harmony and stability within a society. According to Confucianism, the enactment of interpersonal relationships always implies a hierarchy based on various status criteria. Modernization and globalization have rendered Vietnam more open to the outside world, thereby introducing new social values, norms, beliefs, and ways of life. Nevertheless, elements of the country's

Confucian heritage have persisted to the present day and can be seen in the hidden values of Nationalist and Communist doctrines, principles, and ethics and in public opinions. The values of hierarchy remain a particularly energetic force.

Hierarchical Values from the Vietnamese Perspective

The strength and durability of hierarchical values in Confucian cultures influence the guiding societal philosophy in ways that encourage stability and order, avoid instability and chaos, and ultimately protect the *status quo*. Hierarchical values are embedded in Confucian beliefs about social order in which such factors as patriarchy, gender and age roles, and social status are strongly emphasized. In this respect, the Vietnamese perception of the world arising from Confucian values and beliefs rationalizes and legitimizes the hierarchical order of society, making hierarchy itself part of the intrinsic structure, a state of affairs that is both natural and unalterable. The Vietnamese have inherited Confucian teachings on the proper structure of society and education, which places heavy emphasis on absolute obedience to one's parent, elder, teacher, and/or superior. The authority of the parent, elder, teacher, and superior is thus unquestioned, and the obedience owed him or her is absolute (Slote 1998). As in other Confucian societies, this hierarchical pattern has over time become deeply imprinted on familial, organizational, and societal structures. Knowing one's place and proper role in the family, school, workplace, and society is vitally important and takes precedence over any individual considerations and desires. The Vietnamese expect those younger and of a lower social status than themselves to respect them and those further up the hierarchy. Within the discourse of hierarchy, a senior or elder's criticism of a junior is taken for granted, whereas the other way around is not morally convincing, even if legally permissible. Older people rarely accept younger people's initiatives, opinions, or critiques but expect instead to be respected by virtue of their experience, knowledge, and wisdom (Ashwill and Diep 2005).

Hierarchical Values in Harmony and Relationships

At the heart of Confucian discourse lies the notion of “right” relationships. Every person is entwined in a web of relationships and defined by such roles as ruler, minister, father, husband, wife, son, and brother or sister. In the matrix of these relationships, an individual’s position defines his or her responsibilities and obligations and determines the “right” speech, behavior, and actions that he or she must produce to build a harmonious family, organization, or society. Everyone is required to adhere to the responsibilities inherent in the five basic relationships: that between ruler/superior and ruled/subordinate, father and son, husband and wife, elder and younger brother, and friend and friend (Young 1998). These relationships are built upon a hierarchal mechanism by which one person is in charge of another. With the exception of the fifth relationship (friend to friend), all involve the authority of one person over another. The power and the right to rule belong to those in superior positions.

Social order is maintained by strict principles of human relations, both within the family and within society. Relationships are based on the position and role of the parties concerned and bound by the discourse of respect and obedience. In sum, Confucian principles enforce absolute respect and obedience to parents by children, to husbands by wives, to superiors by subordinates, and to teachers by students.

Hierarchical Values in Terms of Change

Change involves risk and thus is not always readily accepted even when acknowledged as necessary for development (Ashwill and Diep 2005). Given the promotion of the *status quo* inherent in Confucian societies such as Vietnam, reform or change is particularly problematic. The “reform of [Confucian] society begins at the top, among the rulers, and then reaches down to the lower orders of society” (Noss 1974, p. 280). It thus comes from seniors, and if they do not initiate change, juniors will accept the *status quo* without question. Change in terms of learning and teaching attitudes is also an issue. Confucian teachings place heavy emphasis on absolute obedience to

teachers. Ferguson (2001) makes this analogy: “If Confucianism is a religion, then the teacher is the minister or priest” (p. 20). Vietnamese students consider their teacher to be a living knowledge resource and a person who knows all. They expect their teachers to know everything there is to know about a given subject and accept what they are taught without criticism or question. This learning attitude is so prevalent that many educators and policymakers state that although Vietnamese students are intelligent, they lack self-reliance and creativity.

Hierarchical Values in Terms of Self-Cultivation and Role Models

Confucianism values self-cultivation, which can be seen as lifelong learning. Great significance is placed on the ability of each individual to learn, to become educated, and eventually to become a moral and upstanding person. Self-cultivation involves not only educating oneself, but also picking up on the good traits of others and then imitating and modeling oneself on them. According to Confucius, if you want to be the king of the world, you must first become the king of yourself. You have to undergo self-cultivation to become a model of integrity, ethics, honor, and propriety. You cannot transform the world without first transforming yourself. Each person (each man in Confucius’s day) must continually improve himself by learning to become a “gentleman.” Confucius described the importance of being a gentleman, or noble man, as follows: “The character of the noble man is like [the] wind; the character of the petty man is like [the] grass. When the wind blows over the grass, [the grass] must bend” (*Analects* 12.19, as cited in Goldin 2011, p. 24).

Confucian Values Reflected in School Leadership

Reflection of the Hierarchy-Penetrated Mind in Exercising Power

The hierarchical values of Confucianism are emphasized in leadership practice in Vietnamese schools. They are embedded in types of leadership

and management behavior that are traditionally associated with “power over,” which emphasizes hierarchical traits, i.e., controlling, coercing, obedience, and domination. The concept of power is reflected in both teachers’ and school leaders’ perceptions and in school leadership practice, with all school members accepting the unequal distribution of power. School leaders generally work according to managerial instructions and directives from senior education officials and are unwilling to openly question the reasoning behind them even if they are found to work poorly in practice. Within the school, they expect obedience and compliance from teachers and staff and consider such obedience and compliance to be indispensable features of effectiveness in the process of exercising power. Demonstrating obedience and compliance is a fundamental obligation of subordinates, and seeking and reinforcing them a fundamental right and managerial duty of school leaders. Hence, there is a high degree of acceptance of unequal power distributions in Vietnamese schools, with teachers and leaders alike highly tolerant of hierarchical and authoritative leadership styles.

The acceptance of unequal power distributions within schools also stems from the belief that individuals play different roles and hold different positions in their families, organizations, and society at large. Accordingly, in the Vietnamese mind, power is intimately connected to one’s roles and position to others, and thus leaders and teachers alike believe that those in a superior position have the right to exercise absolute authority over and demand absolute obedience from those in an inferior position. Managerial order is established to facilitate the management process, and school leaders must be ready to use the power at their disposal to enforce policies and demonstrate and maintain their superiority.

Unequal power distributions exist in all Confucian societies in which hierarchical structures and values are prevalent in families, groups, organizations, and society at large. In other words, the Vietnamese perceive a hierarchy in every aspect of life. One of the main characteristics of the power distribution in Vietnamese schools is ingrained respect for seniority (in terms of

working position and age), which means that leaders are considered superior and deserving of respect by virtue of their high-ranking position rather than their expertise or managerial ability. Similarly, older teachers are granted respect because of their age, regardless of their position. Such hierarchical values promote unequal power distributions in many Vietnamese contexts, including the school, and encourage the practice of “power over” leadership.

Hierarchy-Oriented Relationships

Hierarchical relationships are common in Vietnamese schools, for example, leader-teacher relationships and older teacher-younger teacher relationships. Although these relationships are perceived as based on mutual respect, position and status are emphasized. The value of harmony is believed to be very important and is thus carefully cultivated, although the preservation of harmony in practice is hierarchy oriented. The concept of equality exists in relationships between colleagues of the same position and age, but not in relationships between leaders and teachers or between school members of different generations. The school culture is thus bound by traditional norms of hierarchy. Teachers, regardless of their age, generally believe that school leaders should be respected by all school members solely by virtue of their leadership position. Although leaders generally earn respect by demonstrating such leadership traits as morality, expertise, managerial competence, and charisma, respect is also believed to automatically adhere to the leadership position. Respect for authority is understood to be compulsory. It is subordinates’ duty toward their superiors.

Teachers in Vietnam are very reluctant to challenge school leaders. They often exhibit a humble attitude toward leaders and avoid giving direct feedback on their managerial decisions or performance. Such behavior is a reflection of the hierarchical values governing human relations in Vietnamese society. Relationships are built on obligatory roles and individuals’ positions relative to others and are bound by the discourse of respect and obedience. Hence, the behavior of teachers and school leaders generally differs from that

found in Western societies, which place less value on hierarchical values and tend to feature low degrees of power distance. In Australia, for example, Dimmock and Walker (2002) found that respect for the school leader is not automatic. It has to be earned rather than attained simply by virtue of enjoying leadership status or holding a position of authority. Australian school leaders' perception of harmony is quite different from that of their Vietnamese counterparts. Australian school leaders believe that "sometimes [there is a] need to challenge harmony to change things" (Dimmock and Walker 2005, p. 139), whereas "challenging harmony" in Vietnam is believed to lead to conflict and disorder.

Hierarchical values also exist in relationships between leaders and older teachers, although they differ from those with younger teachers. Leaders are granted respect by virtue of their higher organizational position and authority, whereas older teachers are granted respect by virtue of their age, regardless of their position. Such values shape relationship-building strategies and influence the choice of conflict management approaches. Leaders are willing to criticize younger teachers directly and to use their positional power to force them to follow instructions. However, they may feel uncomfortable about criticizing older teachers. Doing so in public would be considered an insult, leading to a loss of face and possibly a broken relationship. Accordingly, leaders often exercise power over older teachers via a persuasive rather than coercive approach.

Large bureaucratic educational systems with a high degree of centralized control also reinforce the traditional value of respecting authority. The Vietnamese educational system has traditionally been centralized. Schools are told what to do, and the principal's job generally involves implementing decisions made by the Ministry of Education or its offices. The pyramidal structure inherent to traditional bureaucracy affords school leaders little opportunity to review government policies or refuse to comply with senior administrators' decisions. Such leadership practices are "power concentrated," that is, characterized by top-down leadership, respect for seniority, top management goal setting, and the acceptance of

a large power and status differential between school leaders and teachers.

Leaders as Role Models in Exercising Leadership

"Leader as role model" is a significant concept in the Vietnamese school context. Setting a good example or serving as a good role model is an important part of exercising leadership. Leaders are expected to set a good example in their leadership practices and to set the moral standards and working rules that their subordinates follow. The idea is that subordinates will be inspired and motivated by a leader who models appropriate behavior, performs his or her duties in a responsible manner, and avoids improper actions. To encourage subordinates to exhibit strong performance, leaders must prove their leadership qualities by demonstrating strong performance themselves. In this way, they can inspire subordinates to emulate and place their trust in them.

Conclusion

In summary, traditional hierarchical values influence the behavioral patterns that shape leadership practices in Vietnamese schools, with school members entwined in a web of hierarchical relationships and defined by their roles as leader, older teacher, younger teacher, or student. These distinctive roles define the responsibilities and obligations that are expected, as well as the "right speech" and "right behavior" needed to build and maintain harmonious relationships with others.

Despite having been exposed to Western values of leadership, concerns about the need to promote democracy and empowerment, and decentralization in school administration, Vietnamese school leaders' views and practices of leadership and management remain driven by the country's Confucianism-inflected national culture and hierarchical leadership discourse. Traditional management values such as respect for seniority and authority are maintained and reinforced by a combination of politics and a cultural emphasis on hierarchy.

Conscientization, Conscience, and Education

Keqi (David) Liu

Lingnan Normal University, Zhanjiang, China

Introduction

Freire's conscientization has offered not only the language of critique but also the language of possibility. This entry investigates what it would mean to incorporate the cultivation of conscience into conscientization. It focuses on exploring the concept of conscientization and its development, the concept of conscience and its cultivation, and the incorporation of the cultivation of conscience into conscientization. It concludes with a number of concerns of how to apply conscientization with its new light in today's educational settings.

Conscientization and Its Development

The original word for conscientization is *conscientizacao* in Portuguese; its essential elements are well elucidated in Freire's two essays in *Harvard Educational Review* in 1970: "Cultural Action and Conscientization" and "The Literacy Process as Cultural Action for Freedom" or the book, *Education for Critical Consciousness* first published in 1973. At the beginning, conscientization referred to the critically transitive consciousness that might overcome the semi-intransitive and naïve transitive state of consciousness, a process in which people become knowing subjects rather than mechanical recipients to achieve a deepening awareness of social, political, and economic contradictions, and of their capacity to transform the oppressive elements (Freire 1973).

The concept of conscientization has been enriched through its commentators, from both positive and negative sides, such as Harris, Giroux, McLaren, Berger, Bowers, and others (see Liu 2014). Roberts' and Torres' studies of conscientization merit particular attention.

According to Roberts (1996), dialogue, a key element in conscientization, is the movement of consciousnesses, socially and culturally constituted and reconstituted through meaningful communication rather than merely a mechanical collection of individual consciousnesses. Hence, knowing the self is often provoked and deepened by knowing others, and the conscientized self is always embedded in a dialogical relation. If this character of dialogue is ignored, conscientization is no longer itself. After a comparative study of both Hegel's and Freire's dialectics of consciousness, Torres (1994, p. 443) noted: while Hegel analyzed "the originating intersubjective genesis of oppression," Freire examined "the social development of the mechanism of oppression as the forms of subordination of consciousness," in a word: "thingification." Hence, through restoring the loss of humanity for both the oppressed and the oppressor, conscientization is a humanizing pedagogy.

Therefore, deeply rooted in transformative praxis of humanization, conscientization is a cultural practice of freedom through purposeful dialogue. It encourages teachers to become cultural workers to engage in a kind of historical, cultural, and political psychoanalysis to decode the limit situations in social reality and the internalization and sedimentation of domination in the mind. However, conscientization was redefined posthumously by Freire (2004, p. 66) as "the building of critical awareness and conscience." Admittedly, there is extensive coverage regarding the importance of developing critical consciousness within Freire's work and that of Freirean scholars, but there is a lack of investigation into the cultivation of conscience and why the latter is crucial to conscientization as a distinctive process of human development. The question of the cultivation of conscience thus arises.

The Cultivation of Conscience

The notion synonymous to conscience can be found in ancient Greek philosophers such as Stoics, yet the word itself is believed to be first coined by Cicero (Liu 2014). Conscience saw its

full religious development in the medieval age, its full philosophical development in the eighteenth century, and its decline in the nineteenth century because of the domination of empiricism and positivism. However, the exploration of its meaning never stops even in this current age. May's (1983) phenomenological study is more compelling. According to him, the basic components of conscience are a righteous person's active and reflexive consciousness of honoring and preserving humanity in her own person and dignity, and she cannot tolerate seeing herself unworthy of life through her inner scrutiny of self-examination if she does something against humanity. This Kantian interpretation of conscience, according to May, maintains not only inner harmony for the self individually but also social justice for community collectively. This kind of understanding of conscience, essentially compatible with Freire's ethical ideal of humanization, will justify the *raison d'être* of cultivating conscience and make the cultivation of conscience an integral part of conscientization.

The study of how to cultivate conscience starts with two pivotal issues. One is what motivates conscience to work; the other is how to make conscience function habitually. For a better investigation, the notion of "four spheres of living" (see Liu 2014) in Chinese philosophy is drawn on. It can be concisely put as follows. According to Chinese philosophy, humans are different from animals in that when they do something, they are usually conscious of and understand what they are doing. This understanding and self-consciousness give significance to human actions. Thus, the various significances that attach to one's various acts, in their totality, constitute the sphere of living. There can be four spheres of living: the innocent, the utilitarian, the moral, and the transcendent. While the innocent and utilitarian spheres are a natural gift, the moral and the transcendent spheres a spiritual creation.

To live in the moral sphere means to become moral. In this sphere, a person with strong social awareness understands that an individual is merely a member in a whole society, and hence to act for the benefit of the community is taken as the meaning of life. However, as utilitarianism

maintains, in human beings' public relationships, the preference would often be given to selfish over social interests; and in their private morality, a lesser good would be frequently preferred to a greater good because the former is present and easy to obtain while the latter is distant and hard to reach. In other words, the gravity of human desire or selfish indulgence will easily pull human beings down from the moral sphere to the utilitarian sphere.

Moreover, the moral sphere is likely to stick to high principles mechanically or become caged in them. By contrast, the transcendent sphere is the highest level of freedom without negating life fundamentally as an un-self person. It is a kind of spiritual intentionality of overcoming the utilitarian sphere of living. Rather, the utilitarian concern, selfish desire, daily life's mediocrity, and the nausea of moral hypocrisy are expected to be transcended but not to be destroyed. Thereby, transcendence enables a person to achieve a state of enlightenment, in which she may find herself a harmonious union with the self being, the community, and even the universe. In this sphere, to live conscientiously is an integral part of living freely as a citizen of the universe. Only in this sphere can conscience serve as a unifying moral agent to help an individual develop a moral character; and in turn an individual can follow her conscience consistently and assume moral responsibility in any life situations, good or bad. In this sense, transcendence is not only the means but also the highest goal of cultivating conscience. In the end, what it all boils down to is to look for a spirit-inspiring tool of approaching transcendence.

The Kantian rational approach is the most influential: as a universal human faculty in the intelligible human character, reason by itself has a transcendental nature. It is not limited by causal necessity but gives human beings freedom to think and will innately and freely. Equally, the use of practical reason by following the moral law in one's conscience can also make people in the empirical world achieve transcendence. Nevertheless, social psychologists will provide a solid empirical foundation for the Kantian rational approach. According to their experiments with

neurological patients affected by brain damage, the power of reason cannot be appropriated without the motivation of emotion. Therefore, the separation between the body and the mind, particularly the Cartesian way, is an egregious error; and the study of the human mind should take an organismic approach (see further, Liu 2014). Likewise, achieving transcendence also demands a holistic way of combining reason and emotion as an organismic whole. In fact, the noble and sublime human spirit is often inspired by the effulgence out of both high understanding and benevolent feeling. Love and dialogue are thus identified as a powerful transcendent instrument, which is able to draw energetic power out of both reason and emotion. They form the bulk of cultivating conscience.

As Murdoch's (2001) pointed out, because love keeps returning surreptitiously to self-indulgence, the object of love should be fixed on the good, the sovereignty of the spiritual world. Her following remark is compelling:

When true good is loved, even impurely or by accident, the quality of the love is automatically refined, and when the soul is turned towards Good the highest part of soul is enlivened. Love is the tension between the imperfect soul and the magnetic perfection which is conceived of as lying beyond it. And when we try perfectly to love what is imperfect our love goes to its object via the Good to be thus purified and made unselfish and just. (Murdoch 2001, p. 100)

True vision generates right conducts. Love of the good is fundamental to approaching true transcendence.

However, as Fromm (1957) argued, if people are indifferent to life, there is no hope to love the good; thus, love of the good should be embodied in *biophilia*, love of life. Since human beings are seriously alienated in the market society and commercialized culture, love, "the ultimate and real need in every human being," should never be alienated or objectified through pursuing pleasure-giving commodities as a plaything including human beings themselves (p.95). Accordingly, love must be understood as ability, and the development of the power of love is conducive to creating happiness and thereby breaking through the boredom, mediocrity, and absurdity of human existence.

Moreover, communication lies at the center of human existence. It not only forms the basis of love but also helps people break away from the objectification of love. As Buber (1959) noted, the significance of dialogue is not in dialogue itself but in what sort of dialogical relationship is carried out, either I-Thou or I-It. The I-Thou relationship is a mutual subject-subject relationship, in which the I is willing and ready to listen to the Thou based on love and respect; by contrast, the I-It relationship is a possessive subject-object relationship, in which the I knows or uses other persons as things. Providing a human being, irreplaceable, is a creature living in the “between,” dialogue is human existential and ontological reality. Only through dialogue in the I-Thou relation can the self fulfill itself, authenticates itself, and become a whole being.

As Levinas (1969) commented, the Western history of philosophy is a totality of the I without the Thou; it is Buber who filled this blank, but he failed to answer who is this Thou and where is this Thou. After a phenomenological study of the infinity of the other, Levinas (1969) pointed out: “the interlocutor is not a Thou, he [or she] is a You” (p.101). That is, any other in the world I encounter is the Thou. According to him, transcendence is made as pluralism, which “is accomplished in goodness proceeding from me to the other,” herein grows the root of peace (pp. 305–306).

Ontologically, love and dialogue are always bound up together as an enduring marriage in human relations and realities, which closely interrelates with goodness or transcendence. The cultivation of conscience ultimately is a practice-oriented pedagogy of love and dialogue.

The Incorporation of the Cultivation of Conscience into Conscientization

The cultivation of conscience is forever needed to help people build moral character to resist the pressure of a bad situation. However, this resistance might bend in front of armed injustice. If class oppression prevails in a social system, the

talk of morality such as conscience and compassion will turn out to be a spiritual oppression of the oppressed. This is undoubtedly to add insult to the injury of them. Hence, the cultivation of conscience alone cannot go any further if it is not integrated into the revolutionary and social track of conscientization.

To incorporate the cultivation of conscience into conscientization is fundamentally possible. First of all, the cultivation of conscience and the cultivation of critical consciousness are ontologically compatible. As an etymological study shows, conscience and consciousness are close relatives, the word consciousness was originally evolved from the word conscience, and finally the word conscience became increasingly associated with its moral sense of good or bad (Liu 2014). Although the development of consciousness is not equal to the development of conscience, yet one must have consciousness even to define the state of possessing conscience, without which one cannot know or become conscious of conscience. Therefore, consciousness is a permanent home for conscience to reside. Furthermore, in a Hegelian interpretation, conscience marks the highest state of the development of consciousness and acts as a unifying moral agent of consciousness (Liu 2014). Hence, the cultivation of conscience and the cultivation of critical consciousness do complement with each other. More importantly, because cultivating critical consciousness is deeply rooted in social justice and humanization, any social critique and cultural criticism of the problematic system in the Freirean tradition of conscientization are also powerful manifestations of moral courage and ongoing aliveness of conscience. Accordingly, the development of critical consciousness by itself is the development of conscience.

The significance of incorporating the cultivation of conscience into conscientization is remarkable. Retrospectively, the root causes of unnecessary human suffering have been broadly interpreted in two ways: the metaphysical study of human beings that equates human suffering with human nature and the historical study of human

society and the sociological study of human beings that locate a dominant social system and its hegemonic ideology at a particular time as the source of human ills. In terms of the former, human beings possess “selfish genes” from which emerge different moral dilemmas; for the latter, human beings are by nature “good,” and it is the state of societal conditions that determines whether or not this disposition remains or is reconfigured.

It seems that one explanation of the origins of human suffering exaggerates human self-interest and ignores the influence of social factors, while the other acts in the reverse. The enigma, nevertheless, is that human need and biological desire are simultaneously bound up together in and by social, political, and economic systems and ideology as much as they are by each other. This reality demands a holistic approach that is able to address social system problems and human nature problems at the same time. Freire’s redefinition of conscientization, an integration of political pedagogy with moral education, offers a possible breakthrough by mediating this dynamic in a particular way. While the cultivation of critical consciousness is employed to tackle oppression and hegemonic ideology as an integral part of social change, the cultivation of conscience through transcendence can be used to attend egoism, ambition, lust, greed, and other forms of insatiable human desire, which cannot be erased through social change (see further, Liu 2014).

Conclusion: Application Concerns

In terms of applying conscientization, it is vital to realize that the social condition for Freire’s adult education in Brazil is very different from that of this contemporary era. Particularly in the developed countries, owing to the growth of the middle class and the improvement of the living condition for the working class, the social structure has changed, and the explanation of history is no longer dominated by the Marxist class struggle. This does not mean that social classes and

oppression have disappeared but that they take more subtle forms. Accordingly, antialienation or anti-oppression becomes a war of position for genuine democracy through communicative actions and cultural work, of which education is forever the backbone.

As an empowering educational initiative, conscientization for political pedagogy should forever be attuned to sociocultural realities and never be reduced to a fixed method or model for developing individual consciousness or cognition. At this globalization age, the generation of dialogical themes should focus on the concrete dehumanizing operations of power out of and in classroom, dominated by neoliberalism and consumer culture. In this context, radical political education in a classroom setting should never be carried out in a class-struggle manner as what happened during the Chinese Culture Revolution. That kind of political education is another kind of alienation caused by an exaggeration of class struggle, which finally becomes an act of hatred rather than love.

Therefore, considering the complexity and specificity of educating critical consciousness and especially conscience, it is essential to understand that students’ critical consciousness and conscience can only be authenticated by the authenticity of teachers’ critical consciousness and conscience. That is, conscientization encourages every teacher to become alert to any form of discrimination and exclusion and to act responsibly in her own initiative to create more learning opportunities for those most disadvantaged students. Or rather, reading the word and the world in an empowering, sometimes painful, process of conscientization must result in a loving, caring, and dialogical human relationship. This kind of empathetic and equal relationship per se is educative, transformative, and transcendental. It not only inspires those disadvantaged students to break away from poverty and explore a new world ahead of them but also shows them how to love the other in a caring and supportive way. This tradition of conscientization is an invaluable legacy that Freire has left for the world to make both students’ and teachers’ life more meaningful.

Constructing Spaces for Diverse Black Masculinities in All-Male Public Urban Schools

Tony Laing¹ and Cory Brown²

¹The Research Alliance for New York City Schools, New York University, New York, NY, USA

²Murray State University, Murray, KY, USA

Synonyms

[Black males](#); [Masculinities](#); [Sexualities](#); [Single gender schools](#)

Introduction

In American public schools, academic mislabeling and stereotyping of young Black boys has led to them being routinely perceived as threats (Kunjufu 2005a; Ladson-Billings 2011; Noguera 2008; Steele and Aronson 1995). The results include parents and concerned advocates in favor of the education of Black male students calling for the development of alternative educational options such as home schooling, charter schools, or all-male public schools. As regards single-gender public schools, Williams (2010) noted:

[T]he modern movement for single-sex education has its origins in the late 1980s when sex-education first garnered national attention to the widespread reported epidemic of violence... [and] academic underachievement reported to be afflicting a generation of boys and young men. (p. 556)

Giving attention to the educational needs of boys, particularly Black males, has led to initiatives for all-male schools that have found unique ways to address the specific needs of male students. Furthermore, given the state of education for boys at present, single-gender schools are

Article Note The title of this paper is adopted in part from McCready, L. (2010). *Making space for diverse masculinities*. New York: Peter Lang

being “promoted to educators, policymakers, and parents on the grounds that boys and girls learn differently due to underlying biological factors, including hormones” (Williams 2010, p. 557). However, there have been debates regarding single-gender schools set up exclusively for Black male students. District courts throughout the United States have debated the constitutionality of majority-Black male schools; the earliest pivotal case was *Garrett v. Board of Education* (1991). In this case, the plaintiffs alleged that the Detroit Board of Education’s pending decision to open all-male academies in Detroit violated US Constitutional Amendment XIV, Michigan Constitutional Articles 1 & 2, the Equal Educational Opportunities Act, Title IX of the Education Act Amendments of 1972, Michigan’s Elliott-Larsen Act, and Michigan’s School Code through its approval of several male-only academies. On August 26, 1992, a settlement was reached that resulted in the allotment of 136 seats out of 560 to girls. However, “Out of 453 students [who would eventually enroll], 39 were girls, including 1 white student” (Pratt 1997, p. 5).

Advocates of majority-Black male schools state that these schools are in a unique position to help Black male youth, whatever their socioeconomic status, academic level, or cultural background. These schools can push past stereotypes and obstacles that are exceedingly common in traditional public schools, instead helping Black males achieve academic and personal success. Critics point out that within these schools “there is no solid empirical support for this view, and there are little data on the effects and efficacy of single-sex public schools, particularly for students of color” (Goodkind 2013, p. 3). With this information in mind, Fergus and Noguera (2010) used theory of change to introduce two theoretical frameworks to guide the design and implementation of single-sex schools. They note that (1) single-gender schools understand the social and emotional needs of boys and (2) single-gender schools can address the academic needs of boys.

To fully understand the social and emotional needs of Black boys, Fergus and Noguera (2010) outline three objectives: (a) the need to change boys’ ideas of what constitutes a man and a Black

male, (b) the need for an academic identity as part of social identities, (c) and the need for future leadership opportunities that can transform Black boys into leaders. As regard addressing the academic needs of boys, Fergus and Noguera share four objectives: (1) address gaps in academic skills, (2) prepare the boys for college, (3) develop high academic expectations, and (4) make the curriculum and instruction relevant to the lives of the boys.

Single-gender schools have been in existence since the inception of the common school in the United States (Boston Latin 2009). The Boston Latin School, located in Massachusetts, opened in 1635 was the first single-gender school for boys and remained all-male until 1972, when it became coeducational. At present, the number of single-gender schools (in addition to those reserved for Black males) has grown throughout the United States. The National Association for Single-Sex Public Education (NASSPE) reported that, during the 2012 school year, 116 public schools in the United States were single-sex and an additional 390 offered single-sex educational opportunities; in 2002, only 12 provided such opportunities (NASSPE 2012). The proliferation of such schools was made possible by the 2001 reauthorization of the 1965 Elementary and Secondary Education Act (ESEA). The reauthorization of ESEA – also known as the No Child Left Behind Act (NCLB) – allowed for the establishment of both single-gender schools and single-gender classes within coeducational schools.

Regulations passed in 2006 clarified the legal status of single-gender education but also encouraged school districts to establish single-gender schools rather than simply offer girls-only or boys-only classrooms within coeducational schools. (Three types of single-gender public schools exist: (1) public schools that have separate boys’ and girls’ schools located within the same facility; (2) public schools that are entirely female or males; and (3) schools for select grade levels that are entirely single-sex (Nappen 2005, p. 3).) One clarification in these regulations is that the Equal Educational Opportunities Act prohibits the involuntary assignment of students to separate-gender schools. Its inclusion in NCLB revealed that single-sex public schools are believed to

improve the educational experiences and performances of low-income students of color. Many public schools offering single-gender education have high proportions of such youth.

In addition to single-gender public schools, there are single-gender charter schools. The charter school movement is an outgrowth of the economic fears in the United States, exemplified in *A Nation at Risk* which explained the mediocrity in American schools, exacerbated by poor test scores of students in math and science. “Since the inception of the charter school movement in the 1990s three major goals have been set out for them: equity for students, innovation in education programs and competition. These goals are not exclusive; nor should they be presented in isolation” (Lubienski and Weitzel 2010, p. 15).

Like traditional all-male public schools, single-gender charter schools have both critics and proponents. Critics state that students are grouped by academic abilities because these schools are expected to be elite institutions. Specifically, they tend to enroll academically talented students to the detriment of academically disadvantaged students left behind in districts (a practice known as cream-skimming students). (Research has shown that charter schools are serving academically disadvantaged students in proportions comparable to district schools (Garcia 2008).) They contend that single-gender school environments constitute a reversal of the educational gains made since the Civil Rights Movement (Nappan 2005). They also contend that these schools represent a return to segregated schools (Rich 2012) and fail to educate Black males. Some have strict admission requirements that may discourage certain types of students from applying (see Islas 2012).

In making the case for single-gender charter schools, Meyer (2008) argued that single-gender charter schools improve students’ academic performance through three mechanisms: minimizing distractions and harassment from the other sex, addressing gender differences in learning, and remedying past inequities by providing low-income youth of color with opportunities previously afforded only to more privileged youths. However, as Fergus and colleagues (2010) note, this advocacy seems to be based more on

assumptions regarding the needs of low-income youth of color than on empirical research.

One of the primary arguments in favor of single-sex education, particularly for low-income youths of color, is that it minimizes or eliminates distractions originating with the other sex and reduces boys’ sexual harassment of girls, “claims for which there is some supportive evidence” (Goodkind 2013, p. 397). Another argument for single-sex public schools for low-income youth of color is that “they are more prone to sexual distraction than their white and more affluent counterparts, who, it is implied, do not need to be separated in order to concentrate on their work” (p. 398). This argument, Goodkind (2013) further contends, invokes stereotypes about Black hypersexuality. Drury et al. (2012) point out “pressure to conform to gendered ideals is heightened in the single-sex school” (p. 21).

Collectively, single-gender schools allow young men, regardless of their cultural backgrounds, to be nurtured in spaces where their unique challenges, as “stereotyped threats” (Steele and Aronson 1995), are understood. Yet, some of these schools foster exclusivity practices that silence the experiences of male students with diverse sexual orientations, or they do very little to “constructing spaces for diverse Black masculinities” that recognizes differences in sexual orientation.

Contextualizing Single-Gender Experience

R.W. Connell’s theory of hegemonic masculinity refers to the dominant form of masculinity within the gender hierarchy that subordinates other masculinities (Connell 2005). Hegemonic White masculinity is situated at the top of this hierarchy and refers to the power and subordination of both women and non-white masculine men. According to Laing (2014), single-gender schools are not a one-stop solution to the persistent educational problems that routinely cast Black males as being deviant, criminal, “uneducated,” and bound for prison. (In 2013, Ivory Toldson corrected data used in 2013 in “More Black Men in College than Prison? Wrong”. For more

information visit http://www.theroot.com/articles/culture/2013/02/more_black_men_in_jail_than_college_myth_rose_from_questionable_report/).

In fact, some of these all-male spaces perpetuate the same gender-stereotypes that routinely call into questions regarding sexual orientation that are found in coeducational spaces. For example, Bracey (2007) notes that school labels, such as being identified as gay, are significantly more common for an all-boys' school and often creates a variety of disruptions to learning because the students must resort to defending their identity. Some even fear that single-gender schools would actually increase the number of boys considering same-gender-loving relationships due to their attendance in these schools.

Data collection was conducted by two researchers (The research procedure for the high school included eight one-on-one (1 h) interviews with Eddy, Lex, Max, Franky, Kevin, Henry, Samuel, and Kyle; a (30-min) focus group (comprised half of the sample); field observations; and one researcher-volunteer tutoring activity (1 h) across six classes, as part of the data collection process. The research procedure for the middle school included three one-on-one interviews with three students and two one-on-one interviews with three teachers, as well as field observations during two academic school years.), at two different single-gender schools (one public middle school and the other a charter high school) and indicated that students must continually defend their choice to attend an all-boys' school to peers who do not attend these schools and to family members (Brown 2012; Laing 2014). Each of the interviewees discussed how they consistently answered questions to determine whether the school catered to gay students. In addition, through observations, the boys readily insulted one another with "gay" and "fag" epithets (The use of such an epithet denotes the questioning of masculinity often by males who have a gender performance that is considered feminine. Such findings are reflected in McCready, L. (2010). *Making space for diverse masculinities*. New York: Peter Lang.) to which the students who were insulted had a strong reaction. More specifically, some boys acted out in school in the hope

that they would eventually be removed from the school. This behavior was indicative of the insults that some of the students receive from peers and others who did not fully embrace the mission of single-gender schools. Peers outside of the schools questioned the boy's sexuality, which led to the development of a hyper-masculine persona on the part of some, and a generalized resistance to the educational environment scrutinized the boys, by others. One middle school teacher in particular noted that, "it's okay for girls to go to an all-girls' school; that's appropriate. But boys [if] they do, are going to turn gay. It's a school for gay boys. We fight that every day." When asked whether this idea contributes to some of the boys' behavioral issues, the teacher posits the following:

You know, having to defend your sexuality at age eleven, or your gender identity, because someone in your family doesn't know any better. Yeah, that would upset me.

That would certainly make me not do anything I could to get good attention. They put them on guard to have to defend who they are may be for the first time in their lives and that's something [significant] for an eleven year old.

A student who noted that he "tells people that it is not a gay school" further reinforced the teacher's point.

In the other school, one interviewee readily admits that he is homophobic, but also can respect "other people's sexual orientations" provided that they do not "bring that touchy, touchy towards me." Some students mentioned that some of their teachers foster mostly traditional definitions and discussions of masculinity in the classroom and through one-on-one-conversations. Although the boys mentioned that they had teachers who understood the importance of diversity, some did not publicly affirm all non-heteronormative forms of masculinity, such as same-gender-loving individuals. This identity marker is not regularly discussed publicly at school-wide events. Avoidance on the part of some personnel of discussions of same-gender-loving individuals defined queer identities as a taboo subject at the school (Laing 2014).

The aforementioned point is significant to the function of single-gender learning spaces for Black males, in particular. Teachers must receive

adequate preparation to address conversations (and avoidance) concerning different sexual orientations, homophobia, and bullying tactics steeped in heteronormative discourse at the school that in turn silences students' voices or promotes the presence of hypermasculinity. If students cannot rely on teachers and administrators to provide an environment that addresses homophobia and sexual inclusiveness, these single-gender schools have not fully accomplished their goals of providing unique learning spaces for Black males to help them overcome societal labels that impede academic excellence.

Curricular Changes in Single-Gender Spaces

In general, a great deal of single-gender schooling relies heavily on brain-based learning strategies that outline various methods to offer optimal pedagogical approaches to teaching. For instance, brain-based strategists note that boys prefer to learn in an environment that is more aggressive and that includes such activities as throwing a ball to a boy as opposed to the having them raise their hand to answer questions or spending time with normal males playing sports (Sax 2005). Conversely, brain-based strategists Gurian and Stevens (2011) and Sax (2005) note that physical discipline would be more appropriate for boys. They have detailed a variety of differences in brain components, such as the hippocampus, hypothalamus, and cerebral cortex, and how boys differ from girls. The failure of their approach is the notion that all boys are the same and want an environment that is generalized to heteronormative standards that define what it means to be a man (Brown 2012).

While Gurian, Stevens, and Sax received validation for their work on brain-based brain functions, including the cognitive development of boys, from educators, policymakers, and parents, their work has also been scrutinized as being heavily exaggerated. Eliot (2009) notes that many of the aforementioned notions, regarding brain science expressed by Gurian, Stevens, and Sax, have not been supported by neurological research and some are

blatantly false. Eliot (2009) specifically states that much of their research is "extrapolated" from single research studies or research conducted on rodents (p. 8). The American Civil Liberties Union (2009) has likewise concluded their research promotes gender stereotypes in schools. Eliot (2012) further notes that how a child develops and how adults enforce gender roles may determine how they function, which thereby suggests cultural inferences.

Fergus and Noguera (2010) note a disconnection between what it means to be a man and what it means to be a learner. The focus of this notion of differences specifically centers on the feminization of schooling. This is a divisive political issue debated by scholars regarding whether feminization has led to a softer curriculum less suitable for boys than for girls. If single-gender schools are to enhance the learning experience of boys who attend such schools, they must be prepared to dismantle what it means to be a man and address sexuality as something that does not define masculinity. Additionally, curricula needs to be designed to present diverse perspectives, written by men and women of all cultural backgrounds to ensure that no student feels that his identity is silenced by teachers and administrators who do not have the skills, knowledge, or patience to address differences.

Concluding Thoughts

"Constructing spaces for diverse Black masculinities" is a call for single gender all-male schools to revamp some institutional practices that routinely silences the experiences of same-gender-loving males. This paper shared some consequences related to how Black male students thought about and define their respective masculinities. Their understandings of the pressures to openly define to their peers, who did not attend all-male schools, whether heterosexual or same-gender-loving, were a direct result of repeated questioning about their sexual orientation because they attended all-male schools. Same-gender-loving males were for the most part completely overlooked as male by some of their peers inside and outside of the schools. In addition, avoidance of discussions regarding the life experiences of same-gender-loving males by some

teachers and male students themselves posed challenges to the types of male circles formed. Theories regarding brain-based research do little to explain how oftentimes these all-male spaces may perpetuate the same stereotypical norms related to gender norms as in coeducational schools. Single-gender all-male schools occupy unique positions for reintroducing more diverse masculinities that recognize diversity. However, this will mean the introduction and recruitment of various types of males at such schools. “Constructing spaces” is the redefinition of “What it means to be male” – more inclusive of differences. Understanding gender identities is a major issue in the lives of young men, in relationship to their peers, family members, and older adult male teachers alike. These social factors combine to explain how some young Black men view themselves and their peer relationships with other males.

Constructivism

Tarso Bonilha Mazzotti

Universidade Estácio de Sá, Rio de Janeiro, RJ,
Brazil

Constructivism refers to the notion according to which knowledge results from a process based on mental operations, or judgments, or the capacity of judgment. Immanuel Kant (1724–1804) proposed that the theoretic or pure capacity of judgment be based on a priori synthetic judgements of space and time. Since then there is a controversy about the reality of those judgements and about its explicative power. In this controversy two antagonistic positions are found: the one that supports the innatism of those judgements and the one that denies it. Between these two positions there is a third one, due to Jean Piaget, that considers that space and time are not a priori, and that the innate aspects are the instinctive acts, from which reasoning is constituted.

The constructivism proposed by Jean Piaget (1896–1980) considers that “the formal obligation of transcending endlessly the systems already constructed in order to assure non-contradiction is convergent with the genetic tendency of surpassing, endlessly, the constructions already finished in order to fulfill lacunas” (*Études d’epistemologie génétique*, vol. 14, p. 324). Genetic, here, has the proper sense of geneses of cognitive forms, but not of heredity. Thus, the schemes and cognitive structures proper of the subject of knowledge [community of scientists and/or community of laymen] are permanently questioned in the process of knowing. This process, essentially constructive, is similar to the Kantian position, but diverges from it in a central aspect: the cognitive construction does not refer exclusively to logical-mathematical beings; it also refers to the process of assimilation of the obstacles, or objects, faced by the subjects of knowledge.

The constructivism proposed by Piaget is, then, a genetic constructivism, that is, for him the cognitive function is the same in any human being and is characterized by the cognitive activities of assimilation and accommodation which make the cognitive

adaptation of the objects [cognitive obstacles]. This adaptation is made through schemes and/or structures constructed by the subject of knowledge when confronted by social and historical needs. In this sense, there is no functional difference between common sense and scientific sense, but only a structural differentiation, since the latter requires the rigor historically developed in a given science. This rigor, by its turn, expresses itself in the methodology of scientific investigation, which is characterized as an applied logic and epistemology (Piaget et al. 1967, p. 3 and Piaget and Beth 1961 followings).

The genetic constructivist point of view has many defenders, among them, Raymond Boudon. This author criticizes several trends found in the sciences of man (French nomenclature), especially in sociology, and proposes a genetic constructivist theory of the knowledge. For Boudon there is no essential difference – functional or of mechanisms – between common sense and scientific sense, but only a diversity regarding the rigor of the argumentation. For him, “the mechanisms responsible for the formation of collective normative beliefs are not different, in principle, from the mechanisms that generate collective ‘positive’ beliefs” [those of science] (Boudon 1998, p. 31). As in the theory proposed by Piaget, the “‘positive’ beliefs,” those that reach some level of validation, differ from the others by their argumentative consistency. Beliefs are justified by arguments either more socio-centered, in the case of the common sense, or less socio-centered, in the case of the sciences. It is important to point out that the fallacies and other argumentative mistakes occur in both conditions (cf. Boudon 1990, 1998).

To constructivism, in the perspective presented, the fact that knowledge is constructed does not imply neither solipsism nor radical relativism, since the problem of its truth is open to the public, that is, to the community of knowers – be them laymen or scientists. Thus, the argumentative correction developed along the history of philosophy and the history of science, through the exposition and criticism of fallacies and sophisms, is relevant to the construction of the scientific knowledge, as well as to police and judicial investigation and, in a way, to the disputes of the

daily life. This fact allows us to say that there is a certain progress or improvements in common sense argumentation. In any case, the rigor required is specific to the social situation in which the argumentation is developed, as noted by Aristotle (*Ethica Nicomachea* 1098a).

The trend known as social constructivism – which has many followers among educational researchers – takes phenomenology as a basis to state that research should consider the meanings and intentions held by the social actors, and, in order to accomplish this goal, the researcher should approach the social groups putting “in parenthesis” his/her beliefs and values. This procedure is necessary because reality is multiple and the researcher, Lincoln and Guba say, “wants to begin his transactions with the respondents in a most neutral way” (apud Alves-Mazzotti and Gewandsznajder 1998, p. 133). For the social constructivists, the multiplicity of possible interpretations about an “object,” all socially justifiable, prevents objectivity, because “realities exist in the form of multiple mental constructions, socially and experientially based, local and specific, dependent, for their form and content, on the persons who hold them” (idem, ibidem). The social constructivism adopts, therefore, the radical relativism, or skepticism, or yet Pyrrhonism, of long tradition in philosophy.

Genetic constructivism is incompatible with social constructivism, since it considers objective knowledge of the world feasible. This knowledge, however, is not a specular representation of the real, but the best approximation in a given moment. For genetic constructivism, one of the main evidences of the quality of a theory is its effectiveness, that is, the fact that it is able to orient the actions of the knowers in order to establish some transformation, or change, in the real. Besides, we have to consider that theories, as formalizations, are possible of argumentative and logic analysis, which show or demonstrate the quality of its statements, which are forms of inference (anticipations). Thus, evaluations that demonstrate errors or mistakes in the arguments should eliminate false or nonvalid arguments. For example, if a petition of principle or sophism occurs in the theoretical argumentation, it should

be put under suspicion, since those errors imply improper or false relations. As mentioned, for social constructivism, arguments and statements about reality are not liable of evaluation neither by criteria proper of the theory of argumentation nor by the various logics, because they are the expression of a perception of the actors involved in the research. In fact, for social constructivism, reality can only be expressed through a personal interpretation, with which the others can agree or not, but this is irrelevant since there is no foundational criteria that allow us to say which interpretation is the correct. Thus, although explicitly opposing empiricism (in general called “positivism”), social constructivism assumes, implicitly, the empiricist thesis of the identity between statements and reality as the only criterion for the establishment of valid theories. As, in fact, the empiricist thesis is improper, then there is no possibility of valid knowledge, say the social constructivists, disregarding any other constructive alternative (cf., among others, Boudon 1990, 1998).

For genetic constructivism the relation between theory, or models, and reality is one of approximation. Its validity can be demonstrated in several ways, among which those of argumentative strength and efficacy (efficiency and effectiveness). Nevertheless, for that theory there is no reason for claims neither of absolute truth nor of impossibility of significant knowledge. It rejects, therefore, both Pyrrhonism and idealism (Kantian and Hegelian).

Convergence of Inclusive Education and Disability Studies: A Critical Framework

Katie Roquemore

Syracuse University, Syracuse, NY, USA

Disability studies is an academic field of study that emerged alongside the Disability Rights Movement. Disability studies is an interdisciplinary field which acknowledges that disability “sits at the intersection of many overlapping disciplines in the humanities, sciences, and social sciences” (“What is Disability Studies?”). Goals of disability studies scholars and programs include: challenging the view of disability as an individual deficit that can be fixed through medical intervention or rehabilitation; exploring models and theories that examine economic, political, cultural, and social factors that define disability; working to destigmatize disease, illness, and impairment; and interrogating the connections between medical practices of disability and stigma (“What is Disability Studies?”). Disability studies has numerous philosophical foundations that relate to the various political, social, and economic aspects of disability and society as a whole.

One such philosophical and interdisciplinary foundation is Disability Studies in Education (DSE) which emerged out of the recognition of a need for serious inquiry in the field of education using a disability studies framework. DSE questions constructions of disability and challenges assumptions and practices of special education (Taylor 2008).

Special education services only came about after legislation was passed requiring public education for students with disabilities. In 1975, a landmark piece of legislation changed access and equity to schooling for students with disabilities: The Education for All Handicapped Children Act (EHA), later renamed the Individuals with Disabilities Education Act (IDEA). The EHA established the right for all children to a free public education regardless of disability, and later, IDEA, requires schools to provide special educational services to students who qualify based on disability. The

IDEA established the philosophy of least restrictive environment (LRE), where children with disabilities are to be educated in environments with the least number of restrictions (Villa and Thousand 2005). The law states that:

To the maximum extent appropriate, children with disabilities, including children in public or private institutions or other care facilities, are educated with children who are not disabled, and special classes, separate schooling, or other removal of children with disabilities from the regular educational environment occurs only when the nature or severity of the disability of a child is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily. (Individuals With Disabilities Education Act, 20 U.S.C. § 1400, 300.1 (2004))

The philosophy of inclusion purported by the LRE is supposed to ensure equity in education, particularly for students with disabilities while benefitting all students. However, as Taylor (2008) points out, for there to be a least restrictive environment there also is a most restrictive one – special education settings happen on a continuum. Critiques of special education suggest that there is a continual “re-emergence of the kind of thinking which leads to ever newer forms of segregative and exclusionary practice” (Thomas and Loxley 2001, p. 5). Special education practices rely on the ability to separate and exclude students despite the philosophies of inclusion practiced at times. Special education and inclusive education are sometimes used interchangeably, but there are differences between the two.

Inclusive education strives for all students with disabilities to be full members of their school communities, with educational settings the same as their nondisabled peers. The philosophy of inclusion was developed as a response to special education that moves away from the charitable and technical views of the role of special education. Inclusive education at its core was to be radical, and it arose from emancipatory ideals that looked forward to a new education system (Armstrong et al. 2010). Inclusive education, from a DSE framework, includes three main guiding principles: (1) inclusive education is fundamentally about all learners; (2) inclusive education strives to make all learners’ experiences at school inclusive and participatory; (3) inclusive education aspires to a

socially just and democratic education and, as such, actively interrogates the cultural practices of schooling (Baglieri et al. 2011). The philosophy of inclusion is less focused on disability and more focused on equity of achievement for all learners.

Philosophical Foundations of Disability Studies

The field of disability studies examines disability as a social, cultural, and political phenomenon. This grounding philosophy leads to the rejection of deficit models of disability, including medical and rehabilitative models. Deficit models of disability assert that people with disabilities have deficits that must be corrected; this is the dominant philosophy of disability (Pfeiffer 2002). While disability studies scholars reject these models, they still pervade society today. In deficit models, disability is always situated within the individual, and this belief influences medicine, rehabilitation, and education. The deficit model in the medical field points to a health deficit; the deficit model in rehabilitation points to an employment deficit; and the deficit model in education points to a learning deficit. In each of these cases, the disability is a fault within the individual (Pfeiffer 2002). In deficit models, disability is understood as physical or mental impairment that has personal consequences for the individual (Wasserman et al. 2015). These deficit models fail to address the social and cultural barriers that people with disabilities face in our society.

Disability studies scholars instead highlight the social, economic, and political barriers that construct people as disabled to rebuff the deficit paradigm and reject the idea that people with disabilities are abnormal. Constructions of normal and abnormal are the basis for deficit models: “normal and abnormal are social judgments of what are and what are not acceptable biological variations and functioning. By classifying people with disabilities as abnormal, these value judgments are used to justify the disadvantages which confront people with disabilities” (Pfeiffer 2002). These value judgments lead to the understanding in deficit models that any limitation a person faces is due to their impairment (Wasserman et al. 2015). Disability studies scholars understand

this stigma through value judgments to be a reflection of the deficit medical models of disability and reject these understandings for a social model of disability that understands impairment and disability as socially constructed.

The foundation of disability studies, however, is not a simple rejection of deficit models of disability. Disability studies is grounded in varied interdisciplinary scholarship that recognizes the complexities of disability. Some critics within disability studies of both social and deficit models of disability say the models present a false dichotomy between biological impairment and social limitation which are present in the disability paradigm (Corker 1999; Hughes and Paterson 1997; Shakespeare and Watson 2001). Further complicating this understanding, biologic classifications of impairments are not objective because such classifications are part of the social process of disablement (Wasserman et al. 2015). While social models of disability may provide more insight into the social, cultural, and political implications of disability than deficit models, critics argue this model is still based in a dichotomy which posits impairment as natural defect and disability as a social characterization of impairment. However, disability studies allows scholars to practice a more political/structural analysis that uncovers exclusionary social practices that are not dependent on the dichotomy of impairment or disability. Often, “social organization according to able-bodied norms is just taken as natural, normal, inevitable, necessary, even progress. . . . The resulting exclusion of those who do not fit able-bodied norms may not be noticeable or even intelligible” (Delvin and Pothier 2006, p. 7). The work of disability studies is to expose the ways in which society defines and interacts with disability that results in oppression, stigmatization, and exclusion, particularly when the grounding philosophies of a society are those that characterize disability as deficit.

The philosophical foundation of disability studies rejects deficit models and instead offers a social model of disability that creates space for critical societal transformations in understanding disability through interdisciplinary work. This

interdisciplinary nature of disability studies can be used as a framework for critiquing specific approaches to disability (Linton 1998). The social model of disability confronts the stigma, discrimination, and assertions of difference and inferiority that are part of the social experience of disability (Pfeiffer 2002). The social model is more critical of social norms than the deficit model and suggests that a moral societal response to disability is to reshape exclusive practices to be inclusive and maximize social participation for people with disabilities (Silvers 2000). The disability paradigm has implications not just for people with disabilities but for society as a whole. People with disabilities must be involved in creating any research using the disability paradigm, and furthermore, a social change must occur, not for people with disabilities, but society must change (Pfeiffer 2002). Disability studies is one academic field that emerged to critique and explore changes in society related to disability.

Philosophical Foundations of Special Education and Barriers to Inclusion

The philosophies underlying special education are in tension with those of inclusive education, and this results in barriers to inclusion for students with disabilities. Two laws were passed in the 1970s which require public schools to provide educational services to children with disabilities – Section 504 of the Rehabilitation Act and what is now called the Individuals with Disabilities Education Act (IDEA). Section 504 of the Rehabilitation Act is civil rights legislation while the IDEA is education law (deBettencourt 2002). In each of the laws, the focus is on the individual and the disability which perpetuates deficit modes of understanding the impact of disability.

The IDEA is the law most commonly cited when referring to special education. Before special education services can be provided for a student, an evaluation team consisting of qualified personnel at the school district must assess the

student. The evaluation team must answer yes to the following questions:

1. Does the student have a disability?
2. Does the disability cause an educational impact to the student's education?
3. Is the student in need of special education or specially designed instruction?

Only when the evaluation team answers yes to all three questions will a student be considered eligible to receive services through special education (Katz 2013). If students must have a documented disability, the medical record or a doctor's note is required by the evaluation team. This documentation usually comes in the form of a diagnosis, a reliance on the medical model of disability. There are 13 different categories of disability under IDEA that qualify students for special educational accommodations: autism, deaf-blindness, blindness, emotional disturbance, hearing impairment, intellectual disabilities, multiple disabilities, orthopedic impairment, other health impairments, specific learning disability, speech or language impairment, traumatic brain injury, and visual impairment (Katz 2013). Often the evaluation team must rely on the use of psychometric testing of students before providing additional services (Zaretsky 2005). For a child to receive special education services, an intervention must occur to identify a problem, or disability. Special education is viewed as rehabilitation for students whose deficits prevent them from learning in general education settings without supports. This philosophy and paradigm results in practices that pathologize disability through the appropriate interventions and cures (Zaretsky 2005). The process of identification and diagnosis of disability situates special education services within the medical realm. Special education's reliance on a medical discourse of disability prevents the field from promoting full inclusion of students with disabilities and is the source of barriers to inclusion.

An alternative philosophy in the education of students with disabilities is one that advocates for a social model that treats disability as natural

difference with the goal of full inclusion and is referred to as inclusive education (Zaretsky 2005). This philosophical foundation is hard to find in schools because special education knowledge continually emphasizes a deficit model that comes from professional scientific knowledge, like diagnostic processes, and paraprofessionals, such as speech and occupational therapists (Slee 2001). A social model would encourage critical reflection of the organizational features and barriers that may interfere with the learning of students with disabilities (Thomas and Loxley 2001). This reflection indicates a shift in focus from the individual to the institution. Similarly, an inclusive model in special education would critique value judgments used to determine what is right or desirable in programs and placements. In educational programs, constructs of difference may replace the current constructs of deviance (in regards to a norm), and this would put greater focus on changing structures that are disabling rather than focusing on the individual (Zaretsky 2005). True inclusive education requires that schools "create and provide whatever is necessary to ensure that all students have access to meaningful learning" and never requires students to possess a set of specific "skills or abilities as a prerequisite to belonging" (Villa and Thousand 2005, p. 3). An inclusive education model is different from a special education model because the foundational beliefs of inclusive education create a disposition based on equity for all students, not just one focused on accommodations and supports for students with labels of disability.

The LRE Principle: Progress and Tensions with Disability Studies

A major tenet of special education is the least restrictive environment clause of the IDEA. Services and settings for students with disabilities are provided on a continuum that goes from the least restrictive to homebound instruction or residential schools (Taylor 2008). The least restrictive environment clause of special education law was influenced by thinking that emerged in the 1960s

advocating for a range of placement options in special education services for students with developmental disabilities. Reynolds (1962) called for a “continuum” of placements for children with disabilities ranging from the “least restrictive” to the “most restrictive” setting. While at the time this was an improvement from the outright exclusion of students with disabilities from schools, it has maintained a philosophy of approved exclusion in special education to this day. The continuum framework creates barriers to inclusion because it legitimizes segregation of students with disabilities.

Oberti v. Clementon (1993) was a landmark case for interpreting the least restrictive environment clause of IDEA. Judge Edward R. Becker wrote, “We construe IDEA’s mainstreaming requirement to prohibit a school from placing a child with disabilities outside of a regular classroom if education of the child in the regular classroom, with supplementary aids and support services, can be achieved satisfactorily” (Villa and Thousand 2005, p. 20). Mandates like this one move special education models toward a philosophy that aligns with that of disability studies by emphasizing the environmental barriers and institutional responsibility, but it still falls short of the mark because exclusion based on individual disability is still allowed. Under the LRE clause, students with disabilities must meet prescribed expectations in order to spend time with their nondisabled peers, an expectation that is contingent on their ability to conform to classroom environments (Mutua and Smith 2008). The allowance of and provision for separate settings in the LRE clause demonstrates that special education is fundamentally designed to segregate, be it physical or instructional, and therefore devalue students with disabilities (Abberley 1987). Despite the progress that has been made in special education toward including more students with disabilities in general education classrooms, the philosophy of segregation found in the LRE clause will continue to create barriers to full inclusion.

Full inclusion asks us to consider the question, “What do you believe should be the goals of public education?” (Villa and Thousand 2005). When special education scholars approach disability as a social construction, they move toward

a space where the philosophy of disability studies philosophies informs and changes special education. The core conflict is between the modernist perspective found in special education, in which knowledge is constructed through the scientific method and results in adherence to a medical model of disability, and the post-modernist perspective, in which disability is seen as socially constructed (Zaretsky 2005). Disability studies in education scholars has begun to deconstruct how exclusion takes place in inclusive school structures (Ferguson and Nusbaum 2012). Inclusive educational practices view disability as a social construction and critique institutional barriers, seeking to include students with disabilities in general education settings regardless of the severity or number of disabilities (Villa and Thousand 2005). By choosing to include students in all aspects of school life, regardless of disability, inclusive schools create a foundation for equity. Not just students with labels of disability benefit from a philosophy of inclusion, but students from all backgrounds benefit from the desired outcomes of inclusive schools.

Creativity, Openness, and User-Generated Cultures

Michael A. Peters

University of Waikato, Hamilton, New Zealand

Creativity and the Global Knowledge Economy

The global knowledge economy comprised of increasingly integrated cross-border distributed knowledge and learning systems represents a new stage of development that is characterized by a fundamental sociality – knowledge and the value of knowledge is rooted in social relations (This entry draws on my Introduction to *Creativity in the Global Knowledge Economy* (Peters et al. 2009)). More than any time in the past, the global economy and society are undergoing a massive transformation from the industrial era to the knowledge economy. This is a shift from an age dominated by the logic of standardized mass production epitomized by the assembly-line in the auto-industry to a logic of decentralized networked communications and communities. In the knowledge economy “intellectual capital”, and a range of information-service industries driven by brain-power are driven by the constant demand for innovation. This does not mean the demise of the industrial economy but rather the development of a new relation between manufacturing and information services that permit the sharing of knowledge through open source models and the continuous redesign of flexible production regimes. It also means the rapid development of “mind-intensive” industries especially in the software, media, healthcare, education, and other “mind-intensive” industries. Increasingly, the move to the “knowledge economy” redefines the value creation process, alters the organization and pattern of work, and creates new forms of borderless cooperation and intercultural exchange. This has led many national government and international organization to plan for a restructuring of economy that increasingly focuses on knowledge, education, and creativity. The “New Club of Rome”, for instance, calls

Course of Study

- [Curriculum as a Governing Device](#)

Creative Commons Licensing

- [Open Educational Resources](#)

this new era the paradigm of an “economy of the intangibles” and predicts “Third Phase Industries”, “sustainable development” and development of “intellectual capital”:

- This means that the intellectual, social, and cultural issues require much higher attention. They are the determinants of “Third Phase Industries” based on creativity, software, media, finance, services, and more generally combined intelligence, which are more representative of today’s developed economies and which produce more value than traditional manufacturing per se. They are of decisive importance to the development of all sectors, including traditional ones. Only through careful and sustainable utilization of the new, non-material resources we will be in a position to better organize material and energy resources which are increasingly in short supply.
- In a word: the ‘Ever More’ of the current economic model of the Western industrial society has outlived its legitimacy. What matters are not mere survival strategies or linear expansion but rather sustainable preservation and development of our prosperity. In order to master the future, we need more intelligent modes of cultivation and exploitation, and a new balance between material and non-material resources.
- Intellectual capital (comprising assets such as human abilities, structural, relational, and innovation capital, as well as social capital) founded on clear, practiced values such as integrity, transparency, cooperative ability, and social responsibility constitute the basic substance from which our future society will nurture itself. (These statements are taken from the New Club of Rome’s 2006 Manifesto.)

The postindustrial society, a term invented by Arthur Pentty, a British Guild Socialist and follower of William Morris, at the turn of the century, was based on craft workshop and decentralized units of government. The post-industrial society is marked by the change from a goods-producing to a service economy and the

widespread diffusion of “intellectual technologies.” For Daniel Bell (1973), the concept of postindustrialism dealt primarily with changes *in the social structure* including the shift from a goods-producing economy to a service economy, the centrality of theoretical knowledge for innovation, the change in the character of work, and the shift from a game against nature to a game among persons. His early account given in the 1970s before the Internet and the spread of communications networks did not foresee the phenomenon of virtualization or the emergence of personalization as a 24/7 totally person-centered, unique learning environment.

Although there are different readings and accounts of the knowledge economy, it was only when the OECD (1996) used the label in the mid-1990s and it was adopted as a major policy description/prescription and strategy by the United Kingdom in 1999 that the term passed into the policy literature and became acceptable and increasingly widely used. The “creative economy” is an adjunct policy term based on many of the same economic arguments – and especially the centrality of theoretical knowledge and the significance of innovation. Most definitions highlight the growing relative significance of knowledge compared with traditional factors of production – natural resources, physical capital, and low-skill labor – in wealth creation and the importance of knowledge creation as a source of competitive advantage to all sectors of the economy, with a special emphasis on R&D, higher education, and knowledge-intensive industries such as the media and entertainment. At least two sets of principles distinguish knowledge goods, in terms of their behavior, from other goods or commodities or services; the first set concern knowledge as a global public good; the second concern the digitalization of knowledge goods.

These features have led a number of economists to hypothesize the “knowledge economy” and to picture it as different from the traditional industrial economy, leading to a structural transformation. In *The Economics of Knowledge* (2004) Dominique Foray argues:

Some, who had thought that the concepts of a new economy and a knowledge-based economy related to more or less the same phenomenon, logically concluded that the bursting of the speculative high-tech bubble sealed the fate of a short-lived knowledge-based economy. My conception is different. I think that the term ‘knowledge-based economy’ is still valid insofar as it characterizes a *possible scenario of structural transformations of our economies*. This is, moreover, the conception of major international organizations such as the World Bank and the Organisation for Economic Cooperation and Development (OECD) (p. ix, my emphasis).

In this scenario “the rapid creation of new knowledge and the improvement of access to the knowledge bases thus constituted, in every possible way (education, training, transfer of technological knowledge, diffusion of innovations), are factors increasing economic efficiency, innovation, the quality of goods and services, and equity between individuals, social categories, and generations.” He goes on to argue that there is a collision between two phenomena – “a long-standing trend, reflected in the expansion of “knowledge-related” investments” and “a unique technological revolution.”

Knowledge As a Global Public Good

The first set of principles concerning knowledge as an economic good indicate that knowledge defies traditional understandings of property and principles of exchange and closely conforms to the criteria for a public good:

1. Knowledge is *non-rivalrous*: the stock of knowledge is not depleted by use, and in this sense knowledge is not consumable; sharing with others, use, reuse, and modification may indeed add rather than deplete value.
2. Knowledge is barely *excludable*: it is difficult to exclude users and to force them to become buyers; it is difficult, if not impossible, to restrict distribution of goods that can be reproduced with no or little cost.
3. Knowledge is not *transparent*: knowledge requires some experience of it before one discovers whether it is worthwhile, relevant, or suited to a particular purpose.

Thus, knowledge at the *ideation* or *immaterial* stage considered as pure ideas operates expansively to defy the law of scarcity. It does not conform to the traditional criteria for an economic good, and the economics of knowledge is therefore not based on an understanding of those features that characterize property or exchange and cannot be based on economics as the science of the allocation of scarce public goods. Of course, as soon as knowledge becomes codified or written down or physically embedded in a system or process, it can be made subject to copyright or patent and then may be treated and behave like other commodities (Stiglitz 1999).

Digital Information Goods Approximating Pure Thought

The second set of principles apply to digital information goods insofar as they approximate pure thought or the ideational stage of knowledge, insofar as data and information through experimentation and hypothesis testing (the traditional methods of science) can be turned into justified true belief. In other words, digital information goods also undermine traditional economic assumptions of rivalry, excludability, and transparency, as the knowledge economy is about creating intellectual capital rather than accumulating physical capital. Digital information goods differ from traditional goods in a number of ways:

1. Information goods, especially in digital forms, can be copied cheaply, so there is little or no cost in adding new users. Although production costs for information have been high, developments in desktop and just-in-time publishing, together with new forms of copying, archiving, and content creation, have substantially lowered fixed costs.
2. Information and knowledge goods typically have an experiential and participatory element that increasingly requires the active coproduction of the reader/writer, listener, and viewer.
3. Digital information goods can be transported, broadcast or shared at low cost, which may

approach free transmission across bulk communication networks.

4. Since digital information can be copied exactly and easily shared, it is never consumed (see Shapiro and Varian 1998; Morris-Suzuki 1997; Davis and Stack 1997; Kelly 1998).

The implication of this brief analysis is that the laws of supply and demand that depend on the scarcity of products do not apply to digital information goods.

Creating the Creative Economy

Today there is a strong renewal of interest by politicians and policy-makers worldwide in the related notions of creativity and innovation, especially in relation to terms like “the creative economy,” “knowledge economy,” “enterprise society,” “entrepreneurship,” and “national systems of innovation” (Baumol 2002; Cowen 2002; Lash and Urry 1994). In its most obvious form, the notion of the creative economy emerges from a set of claims that suggests that the industrial economy is giving way to the creative economy based on the growing power of ideas and virtual values – the turn from steel and hamburgers to software and intellectual property (Florida 2002; Howkins 2001; Landry 2000). In this context, increasingly policy latches onto the issues of copyright as an aspect of IP, piracy, distribution systems, network literacy, public service content, the creative industries, new interoperability standards, the WIPO and the development agenda, WTO and trade, and means to bring creativity and commerce together (Cowen 2002; Shapiro and Varian 1998; Davenport and Beck 2001; Hughes 1988; Netanel 1996, 1998; Gordon 1993; Lemley 2005; Wagner 2003). At the same time, this focus on creativity has exercised strong appeal to policy-makers who wish to link education more firmly to new forms of capitalism emphasizing how creativity must be taught, how educational theory and research can be used to improve student learning in mathematics, reading, and science, and how different models of intelligence and creativity can inform educational

practice (Blythe 2000). Under the spell of the creative economy discourse there has been a flourishing of new accelerated learning methodologies together with a focus on giftedness in the design of learning programs for exceptional children. (See The Center for Accelerated learning; see e.g., The Framework for Gifted Education.) One strand of the emerging literature highlights the role of the creative and expressive arts, of performance, of aesthetics in general, and the significant role of design as an underlying infrastructure for the creative economy (Caves 2000; Frey 2000; Frey and Pommerehne 1989; Ginsburgh and Menger 1996; Heilbrun and Gray 2001; Hesmondhalgh 2002). There is now widespread agreement among economists, sociologists, and policy analysts that creativity, design, and innovation are at the heart of the global knowledge economy: together creativity, design, and innovation define knowledge capitalism and its ability to continuously reinvent itself. For innovation theory, see the Danish economist Bengt-Ake Lundvall’s webpage and especially his concept of “the learning economy” (Lundvall and Archibugi 2001; Lundvall and Johnson 1994; Lorenz and Lundvall 2004); see also Globelics, The Global Network For The Economics Of Learning, Innovation, And Competence Building Systems). The notion of knowledge, learning and creative economies has a diverse, critical and seminal literature from a range of different disciplines including contributions from sociologists, philosophers, economists, media and education, for example: Bourdieu (1986), Cardoso and Castells (2006), Castells (1996/2000), Coleman (1988), DeLong and Summers (2002), Drucker (1969, 1993), Granovetter (1973, 1983), Harvey (1989), Hayek (1937, 1945), Hearn and Rooney (2008), Lessig (2006), Lyotard (1984), Nonaka and Takeuchi (1995), Peters and Besley (2006), Porat (1977), Powell and Snellman (2004), Prusak (1997), Putnam (2000), Quah (2003a, b), Romer (1990), Rooney et al. (2003), Soderberg (2002), Tapscott and Williams (2007), Toffler (1980), Touraine (1971). Together and in conjunction with new communication technologies they give expression to the essence of digital capitalism – the “economy of ideas” – and to new

architectures of mass collaboration that distinguish it as a new generic form of economy different in nature from industrial capitalism. The fact is that knowledge in its immaterial digitized informational form as sequences and value chains of 1 s and 0 s – ideas, concepts, functions, and abstractions – approaches the status of pure thought. Unlike other commodities, it operates expansively to defy the law of scarcity that is fundamental to classical and neoclassical economics and to the traditional understanding of markets. As mentioned above, a generation of economists has expressed this truth by emphasizing that knowledge is (almost) a global public good: it is non-rivalrous and barely excludable (Stiglitz 1999; Verschraegen and Schiltz 2007). It is non-rivalrous in the sense that there is little or marginal cost to adding new users. In other words, knowledge and information, especially in digital form, cannot be consumed. The use of knowledge or information as digital goods can be distributed and shared at no extra cost and the distribution and sharing is likely to add to its value rather than to deplete it or use it up. This is the essence of the economics of file-sharing education; it is also the essence of new forms of distributed creativity, intelligence, and innovation in an age of mass participation and collaboration (Brown and Duguid 2000; Tapscott and Williams 2006; Surowiecki 2004).

Openness and Creativity

There is a long established literature on openness and creativity in the field of personality psychology emphasizing the uniqueness of the individual. Prabhu et al. (2008, p. 53), for instance, report that four decades of work have generated more than 9,000 published studies. They also report that in the five factor model of personality – based on openness to experience, conscientiousness, extraversion, agreeableness, and neuroticism – “openness to experience has the most empirical support as being closely related to creativity.” In this context, openness is correlated with the appreciation for art, emotionality, sense of adventure, new ideas, imagination, curiosity, and variety of

experience. On this psychological reading, open people prefer novelty and change, and tend to be more aware of their feelings with a corresponding will to tolerate diversity and entertain new ideas. Those people with “closed” personality, by contrast, tend to exhibit more traditional and conventional interests and prefer familiarity over novelty and change. The five factor personality psychology is purely descriptive rather than being theory driven and current research is testing the cross-cultural and social validity of the program. While it is still in progress, this research at least raises the strong possibility of the close correlation of openness with creativity at the level of individual personalities emphasizing the relation to concepts of measured intelligence, achievement, and political attitudes (Simonton 2000; Aitken Harris 2004; Dollinger 2007).

Individualist approaches to the relation of openness to creativity can only take us so far. The National Academy of Sciences’ (2003) report *Beyond Productivity: Information Technology, Innovation and Creativity* began by recognizing the crucial role that creativity plays in culture and the way in which at the beginning of the twenty-first century, “information technology (IT) is forming a powerful alliance with creative practices in the arts and design to establish the exciting new domain of information technology and creative practices.” Others such as Richard Florida (2004) have emphasized that the USA needs to invest more in the development of its creative sector as a basis to sustain its competitiveness from the rate of technological innovation and economic growth. Florida (2002, p. 21) argues “human creativity as the defining feature of economic life. [New] technologies, new industries, new wealth, and all other good economic things flow from it” and he goes on to write “[Human] creativity is multifaceted and multidimensional. It is not limited to technological innovation or new business models. It is not something that can be kept in a box and trotted out when one arrives at the office. Creativity involves distinct kinds of thinking and habits that must be cultivated both in the individual and in the surrounding society” (p. 22). Rutten and Gelissen (2008) test Florida’s creativity and diversity hypothesis for European

regions indicating that results indicate that regional differences in diversity are directly related to differences in regional wealth.

The relations between openness and creativity are brought out even more forcefully through the concept and practice of open innovation. Peter Teirlinck and Andre Spithoven (2008) indicate that the increasing complexity of innovation has encouraged companies to use external knowledge sources to complement in-house activities, attempting to substitute a nonlinear feedback model for the old linear model, capturing the benefits of the learning process within, and between, firms and other organizations. As innovation networks grew even more complex, firms adopted the “new imperative” for creating and profiting from technology in the model of open innovation where innovation becomes increasingly distributed among various partners (Von Hippel 1988). They write:

The notion of open innovation is the result of the increasing complexity of innovation and how innovation management should cope with this complexity. It reflects an ever changing research environment (Chesbrough 2003): the increasing mobility of knowledge workers; the applicability of research results of universities to enterprises; more widely distributed knowledge; erosion of oligopoly market positions; more deregulation and an increase in venture capital. This resulted in an open stage gate process with the following features: (1) the centralized inhouse R&D laboratory is no longer the main source of ideas or knowledge and is being complemented by other enterprises, new technology based start-ups, universities, and public research centres; (2) commercialization also occurs outside the traditional markets of the enterprise through licensing, spin-offs, and research joint ventures; (3) the role of the first mover advantage becomes more important than the development of a defensively orientated system of knowledge and technology protection (p. 689).

This model of open innovation is made possible through “creativity support tools” which help to accelerate discovery and innovation. Ben Shneiderman (2007) notes that new “generations of programming, simulation, information visualization, and other tools are empowering engineers and scientists just as animation and music composition tools have invigorated filmmakers and musicians”. He goes on to write:

These and many other creativity support tools enable discovery and innovation on a broader scale than ever before; eager novices are performing like seasoned masters and the grandmasters are producing startling results. The accelerating pace of academic research, engineering innovation, and consumer product design is amply documented in journal publications, patents, and customer purchases. Creativity support tools extend users’ capability to make discoveries or inventions from early stages of gathering information, hypothesis generation, and initial production, through the later stages of refinement, validation, and dissemination.

The sustainability of “social creativity” depends upon a greater recognition of the importance of social and material surroundings. As Fischer and Giaccardi (2007) argue “Individual and social creativity can and must complement each other.” They suggest:

Environments supporting mass collaboration and social production such as annotated collections (GenBank), media sharing (Flickr, YouTube), wikis (Wikipedia), folksonomies (del.icio.us), and virtual worlds (Second Life) are other examples of social creativity. The diverse and collective stock of scientific content and artistic or stylistic ideas that individuals and communities share, reinterpret, and use as a basis for new ideas and visions constitutes the vital source of invention and creativity.

They argue that creativity needs the “synergy of many” which can be facilitated by meta-design – “a sociotechnical approach that characterizes objectives, techniques, and processes that allow users to act as designers and be creative in personally meaningful activities” and they note a tension between creativity and organization. Organizational environments must be kept open to users’ modifications and adaptations by technical and social means that empower participation to serve the double purpose: “to provide a potential source for new insights, new knowledge, and new understandings; and to provide a higher degree of synergy and self-organization.”

The relationship between creativity and open systems especially in computing is growing in significance. Colin G. Johnson (2005) draws a strong set of connection between openness, creativity, and search processes. He begins by noting that “One characteristic of systems in which creativity can occur is that they are open. That is, the space being explored appears to be (theoretically

or pragmatically) unbounded, and there is no easy way in which the structure of the space can be simply summarized.” He suggests that evolutionary search processes (moving from one-to-point, using the information from previously visited sites) are seen as creative for one of three reasons:

Firstly because the criteria for evaluation are not easy to capture in a rulebound fashion. An example of this is searching a space of melodies for ‘interesting’ or ‘tuneful’ melodies. Secondly because the search space is seen as having some complexity which belies ‘easy’ search. Examples of this [sic] ideas include the use of search to explore the space of designs for mechanical devices or electrical circuits. Even though an exhaustive search would turn up the same result as a ‘creative’ search, both the size of the search space and the complex structure thereof (e.g. it is not possible for a ‘naïve’ thinker to conceive of how to specify and order the ‘all possible’ designs). Thirdly, because the search space is seen as being extensible. Consider the idea of searching a space of melodies as discussed above. In order to search this space, we will need to give a description of what a ‘melody’ is[e.g. a sequence of notes in a particular key. However this definition has limitations: what about a melody that changes key half way through? So we expand the search space to include such melodies, then The search space can always be extended. It is these latter two characteristics which seem particularly to capture the idea of ‘openness’ in creativity (Colin G. Johnson).

Open source in computing developed around Linux as an operating system where in such open systems intellectual property is seen as “open” and is made freely available, allowing people to use ideas and code without locking them up as proprietary intellectual property. It is based on three essential features (Tippett 2007), updated from Weber (2004):

...

- source code is distributed with the software, or made available at no more cost than distribution (this means that users can see and change the actual mechanisms that makes the software work);
- anyone may distribute the software for free (there is not obligation for other users of the software to pay royalties or licensing fees to the originator);
- anyone may modify the software, or develop new software from the original product, and the modified software is then distributed under the same terms as the original software (e.g., it remains open).

As Weber comments, these concepts represent a fundamentally different concept of property, typically seen as:

a regime built around a set of assumptions and goals that are different from those of mainstream intellectual property rights thinking. The principal goal of the open source intellectual property regime is to maximize the ongoing use, growth, development, and distribution of free software. To achieve that goal, this regime shifts the fundamental optic of intellectual property rights away from protecting the prerogatives of an author towards protecting the prerogatives of generations of users (Weber 2004, p. 84)

The idea of open source still retains concepts of copyright and the rights of the author or creator over their original work. As Tippet (2007) remarks:

It does thus not negate the concept of property within intellectual products, but rather shifts the view of the rights conferred by the property, so that the “concept of property [is] configured around the right and responsibility to distribute, not to exclude”. (Weber 2004, p. 86)

Tippet also usefully documents the emerging field that applies open source to areas of scholarship and creative endeavor outside software:

For example, open source has been explored as a valuable approach in scientific endeavour and making scientific information available (Jones 2001; Mulgan 2005; Schweik et al. 2005). Keats (2003) has explored open source in terms of developing teaching and learning resources for African universities’. In a series of articles looking at the ‘Adaptive State’, the potential value of open source ideas for public policy delivery are explored (Bentley and Wilsdon 2003; Leadbeater 2003; Mulgan et al. 2005). The ideas have been developed in product design, linked to ideas of open innovation, as companies engage with user communities (Goldman and Gabriel 2005), one example being user-led innovation in sports gear. (Fuller et al. 2007)

Digital technologies have become engines of cultural innovation, and user-centered content production has become a sign of the general transformation of organizational forms. But the transformation of digital culture also transforms “what it means to be a creator within a vast and growing reservoir of media, data, computational power, and communicative possibilities.” We are only now beginning to devise understandings of the power of databases, network representations,

filtering techniques, digital rights management, and the other new architectures of agency and control and “how these new capacities transform our shared cultures, our understanding of them, and our capacities to act within them” (Karaganis 2008).

As Jean Burgess (2007) comments in *Vernacular Creativity and the New Media*

The manufacturers of content-creating tools, who relentlessly push us to unleash that creativity, using—of course—their ever cheaper, ever more powerful gadgets and gizmos. Instead of asking consumers to watch, to listen, to play, to passively consume, the race is on to get them to create, to produce, and to participate (p. 7).

She goes on to register the development of a new vocabulary that speaks of a participatory culture based on creation and user-generated content.

In game environments particularly, terms like “cocreators” (Banks 2002) and “productive players” (Humphreys 2005) are increasingly gaining purchase as replacements for “consumers,” “players,” or even “participants.” These reconfigurations force us to consider the “texts” of new media to be emergent – always in the process of being “made”; further, “cocreation” is built around network sociality and the dynamics of community, prompting a reconsideration of the idea of the individual producer or consumer of culture – even as corporate content “owners” continue, in varying degrees, to assert rights that have their basis in the romantic notion of the individual creative author. It is not only the “who” of production that is transformed in contemporary digital culture, but the *how* (pp. 7–8).

And Burgess details three important structural transformations from the point of view of cultural participation implied by the Web 2.0 model. I summarize from Burgess as follows:

1. The shift from content “production,” “distribution,” and “consumption” to a convergence of all three, resulting in a hybrid mode of engagement called “produsage,” defined as “the collaborative and continuous building and extending of existing content in pursuit of further improvement” (Bruns 2005).

2. A shift from “user-generated content” to “user-led” content creation, editing, repurposing, and distribution; whereby the users of a given web service increasingly take on leadership roles, and where designers and developers to some extent allow the emergence of communities of practice to shape the culture of the network – even to determine what the web service or online community is “for.” This represents a convergence of the “value chain” where users are simultaneously the producers, users, editors, and consumers of the content, leading to “network effects.”
3. The convergence of user-generated content and social software to produce hybrid spaces, examples of which are sometimes described as “social media” – most clearly represented by MySpace, YouTube, and Flickr (Burgess 2007, pp. 10–11).

Burgess (2007, p. 11) argues:

It is this third feature of the new networks of cultural production that has the most profound implications for cultural participation, at least in potential, because this shift opens up new and diverse spaces for individuals to engage with a variety of aesthetic experiences at the same time as their participation contributes to the creation of communities. That is, the significance of ‘Web 2.0’, from a cultural studies point of view, lies in its potential for a new configuration of the relations between the *aesthetic* and the *social* aspects of culture, developed at a grass-roots level.

As many scholars and commentators have suggested since the “change merchants” of the 1970s – Marshall McLuhan, Drucker, and Alvin Toffler—first raised the issue we are in the middle of a long-term cultural evolutionary shift based on the digitization and the logic of open systems that has the capacity to profoundly change all aspects of our daily lives – work, home, school – and existing systems of culture and economy. A wide range of scholars from different disciplines and new media organizations have speculated on the nature of the shift: Richard Stallman established the Free Software Movement and the GNU project (see the GNU site, a 2006 lecture by Stallman entitled “The Free Software Movement and the Future of Freedom” and Aaron Renn’s (1998) “Free”, “Open Source”, and Philosophies of Software Ownership); Yochai Benkler (2006),

the Yale law professor, has commented on the wealth of networks and the way that social production transforms freedom and markets; his colleague, Larry Lessig (2004, 2007), also a law professor, has written convincingly on code, copyright, and the creative commons (see his bestseller *Free Culture*) and launched the Free Culture Movement designed to promote the freedom to distribute and modify creative works through the new social media (see the videoblog Free Culture, Free Software, Free Infrastructures! Openness and Freedom in every Layer of the Network Free Culture, Free Software, Free Infrastructures! Openness and Freedom in every Layer of the Network but see also Pasquinelli's (2008) "The Ideology of Free Culture and the Grammar of Sabotage" at "The Ideology of Free Culture and the Grammar of Sabotage"); Students for Free Culture, (see the website) launched in 2004, "is a diverse, non-partisan group of students and young people who are working to get their peers involved in the free culture movement"; Michel Bauwens (2005) has written about the political economy of peer production and established the P-2-P Foundation (see the foundation and the associated blog); Creative Commons (see Creative Commons) was founded in 2001 by experts in cyberlaw and intellectual property; Wikipedia (see Wikipedia) the world's largest and open-content encyclopedia was established in 2001 by Jimmy Wales, an American Internet entrepreneur, whose blog is subtitled Free Knowledge for Free Minds (see Jimmy Wales' blog at <http://jimmywales.com/>).

One influential definition suggests

Social and technological advances make it possible for a growing part of humanity to *access, create, modify, publish and distribute* various kinds of works - artworks, scientific and educational materials, software, articles - in short: *anything that can be represented in digital form*. Many communities have formed to exercise those new possibilities and create a wealth of collectively re-usable works.

...

- the **freedom to use** the work and enjoy the benefits of using it,
- the **freedom to study** the work and to apply knowledge acquired from it,

- the **freedom to make and redistribute copies**, in whole or in part, of the information or expression,
- the **freedom to make changes and improvements**, and to distribute derivative works (see Definition)

This is how the Open Cultures Working Group—an open group of artists, researchers, and cultural activists—describe the situation in their Vienna Document subtitled *Xnational Net Culture and "The Need to Know" of Information Societies*:

Information technologies are setting the global stage for economic and cultural change. More than ever, involvement in shaping the future calls for a wide understanding and reflection on the ecology and politics of information cultures. So called globalization not only signifies a worldwide network of exchange but new forms of hierarchies and fragmentation, producing deep transformations in both physical spaces and immaterial information domains... global communication technologies still hold a significant potential for empowerment, cultural expression, and transnational collaboration. To fully realize the potential of life in global information societies we need to acknowledge the plurality of agents in the information landscape and the heterogeneity of collaborative cultural practice. The exploration of alternative futures is linked to a living cultural commons and social practice based on networks of open exchange and communication. (See <http://world-information.org/wio/readme/992003309/1134396702>)

Every aspect of culture and economy is becoming transformed through the process of digitization that creates new systems of archives, representation, and reproduction technologies that portend Web 3.0 and Web 4.0 where all production, material and immaterial, is digitally designed and coordinated through distributed information systems. As Felix Stalder (2004) remarks

information can be infinitely copied, easily distributed, and endlessly transformed. Contrary to analog culture, other people's work is not just referenced, but directly incorporated through copying and pasting, remixing, and other standard digital procedures.

Digitization transforms all aspects of cultural production and consumption favoring the networked peer community over the individual author and blurring the distinction between artists and their audiences. These new digital logics alter

the logic of the organization of knowledge, education, and culture spawning new technologies as a condition of the openness of the system. Now the production of texts, sounds, and images are open to new rounds of experimentation and development providing what Staler calls “a new grammar of digital culture” and transforming the processes of creativity which are no longer controlled by traditional knowledge institutions and organizations but rather permitted by enabling platforms and infrastructures that encourage large-scale participation and challenge old hierarchies.

The shift to networked media cultures based on the ethics of participation, sharing and collaboration, involving a volunteer, peer-to-peer gift economy has its early beginnings in the right to freedom of speech that depended upon the flow and exchange of ideas essential to political democracy, including the notion of a “free press,” the market, and the academy. Perhaps, even more fundamentally free speech is a significant personal, psychological, and educational good that promotes self-expression and creativity and also the autonomy and development of the self necessary for representation in a linguistic and political sense and the formation of identity.

Critical and Social Justice Pedagogies in Practice

Mary C. Breunig
Brock University, St. Catharines, ON, Canada

[Critical pedagogy](#); [Educational practice](#); [Social justice pedagogy](#)

Introduction

While pedagogy is most simply conceived of as the study of teaching and learning, the term critical pedagogy embodies notions of how one teaches, what is being taught, and how one learns. Critical pedagogy is a way of thinking about, negotiating, and transforming the relationship among classroom teachings, the production of knowledge, the institutional structures of the school, and the social and material relation of the wider community and society. Critical pedagogy is historically rooted in the critical theory of the Frankfurt School and was greatly influenced by the work of Karl Marx, particularly his views about labor. According to Marx, the essential societal problem was one of socioeconomic inequality, believing that social justice is essentially dependent upon economic conditions. The “New Left scholars” in North America, including Henry Giroux, Roger Simon, Michael Apple, and Peter McLaren (among others), focused their efforts on examining and better understanding the role that schools play in transmitting certain messages about political, social, and economic life. Postmodern currents associated with Derrida, Foucault, Lyotard, Ebert, and others have also problematized the social, cultural, and economic contexts of sources of knowledge and pedagogy. Critical feminist pedagogues argue that education should challenge the structure of the traditional canon and develop and offer alternative classroom practices. Feminist pedagogy reinforces the idea that both the content of the curriculum and the methods of pedagogy employed teach lessons (Breunig 2011).

Critical social theorists, neo-Marxists, liberatory pedagogues, pedagogies of hope and possibility, New Left scholars, educating the Democratic citizen, globalization, and social justice education all offer multiple, (sometimes) overlapping, (sometimes) contested, and varied terminologies to describe critical pedagogy. Despite the varied meanings and approaches, the core of critical pedagogy remains focused on education as a means to bring about a more socially just world (Malott and Porfilio 2011). As Boyles, Carusi, and Attick assert, “The term *social justice*

seems to be in the ears and on the lips” of many educators these days (Ayers et al. 2009, p. 30).

There is a rather extensive body of literature that considers the theory of critical and social justice pedagogies, but significantly less literature that specifically addresses the ways in which professors attempt to apply these theories in practice. How do professors who teach critical and social justice theories practice it within the postsecondary classroom? The academic separation of theory from practice is a manifestation of the ways in which knowledge has become fragmented from lived experience. There have been numerous calls for critical pedagogues to move beyond theory and focus on the formulation of a praxis that acts on the possibilities of critical pedagogy, including within the postsecondary classroom. Paulo Freire (1970) argued that people need to develop critical conscientization and engage educative praxes that incorporate theory, action, and reflection as a means to work toward social change and justice. Malott and Porfilio (2011) assert that there are far too many “theoretical one trick ponies that have an impulsive urge to tear down the work of others” (p. 37). They impel critical pedagogues to move beyond endless critique, deconstruction, and deferral, shifting their energies toward real-world struggles guided by radical love, social justice, and hope. Gramsci (and others) believed that individuals should seek places for counter-hegemonic resistance and solidarity and that the university can serve as one site for the exercise of these practices. The purpose of this entry is thus to consider and convey how scholars might meaningfully and collaboratively engage in social justice praxes with/within postsecondary spaces.

Social Justice Pedagogy in Practice

Gloria Ladson-Billings (2013), a pedagogical theorist and teacher educator, impels educators to consider social justice pedagogy for new century children. These new century students have a deep connection to hip-hop culture, receive their news from the “Daily Show,” and tweet and instant message, viewing email as antiquated. They are “shape-shifters” (p. 108), according to Ladson-

Billings. They do not fit neatly into the rigid categories of race, class, gender, sexuality, or national origin that have been used to make distinctions, create hierarchy, and use as comparators. Talk of “safe space” in the classroom, genuine dialogue, disrupting hierarchies, and encouraging student voice may be simultaneously relevant for critical pedagogues and outdated for these new century students. Paulo Freire (1970) writes about praxis, involving theory and practice, reflection, and action as activism. In this sense, action is not just an activity for the sake of doing something but an activity that is purposeful, social justice oriented, and relevant to a changing society.

Getting Started (or a Bit Further Along)

Schools themselves are constructed through linguistic, cultural, social, and pedagogical specific interactions which both shape and are shaped by social, political, economic, and cultural dynamics and norms. From this perspective, “societies, communities, schools, teachers and even students engage in oppressive practices” (Ayers et al. 2009, p. 569). Building upon the aforementioned concepts of Gramscian counter-hegemonic praxis and Freire’s critical conscientization, how might a social justice pedagogue engage in schools in a manner that offers a counter-narrative to this dominant/normative (potentially oppressive) institutional one?

Something as seemingly basic as trying to schedule a room with movable chairs in it can be a challenge. Trying to combine theory with meaningful praxis and ample reflection in 3 h time blocks can be a restraint within these “fixed” classroom spaces. In many ways, critical/social justice pedagogy is a slow pedagogy. Originating in principles from the slow food movement, slow pedagogy offers a “slow living” perspective which challenges the dominant narratives of institutional norms. Slow is therefore a counter-hegemonic concept, which strikes at the core of neoliberal rationality. Environmental educators Philip Payne and Brian Wattchow (2009) have devised an experiential learning program that draws upon aspects of the principles and practices of the slow movement in order to provide students with a learning experience that does not fit

“neatly” into traditional time blocks. This kind of critical, experiential praxis challenges the orthodoxies of speedy pedagogy and points the way toward an educational alternative that might create the kinds of citizens that social justice pedagogues desire.

How might new century students and pedagogues think beyond the bounds of classroom spaces and time? Certainly online courses, flipped classrooms, and using university-based technology systems provide some means for engagement beyond the “traditional” concept of classroom. But how might we improve upon the design of a learning environment even more – one that encourages students to think and act beyond the bounds of the classroom walls and time/frame? How do we increase our focus on contemporary literacies (digital, media, community, and global) and ways to engage (social production, social networks, media grids, semantic web, nonlinear learning) and integrate students into the very design of our courses and instructional practices (Zmuda et al. 2015)? Equally important to ask ourselves is, “Is collaborative design and engaging new medias an aspect of course development that best ‘fits’ with the class purpose and intent?” Too often, there is an appeal in engaging in the “new” with too little regard for the additive aspect of what this may offer.

“Can you please lecture more often?” is a query that professors may often hear when they collaborate with students on course syllabus and classroom design. “You hold the relevant expertise” is an adage that students may invoke, in large part because their previous preparation has most often “trained” them to believe that the teacher is the one who delivers the knowledge and the student is the one who accepts whatever gets “deposited” (Freire 1970). The neoliberal argument that schools must align their policies and practices with the notion of knowledge as a tradable commodity, one based on efficiency and accountability, offers little to the counter-hegemonic social justice pedagogue and student. “What value does this ‘academic’ exercise of collaboration offer?” is often the resultant query. With many students going on to think (if not articulate) that this kind of educational approach is certainly out of sync

with the neoliberal discourse that predominates the work/world, is it worth it then or not?

A Slippery Slope

“Will you be marking us on APA for this assignment and do you want it double-spaced Times New Roman font size 12? I am really hoping to put effort into this and get an A, so knowing this would really be helpful!” These questions and expressions frustrate many critical pedagogues. Not only does it speak to the institutional norms that students have clearly learned well, but it speaks to their focus on good grades and “pleasing” the professor that is so much a part of “traditional” education. Bell Hooks (1994) discusses how learning emphasizes silent, passive obedience, even in postsecondary schools. As the mystic poet and philosopher, Rumi, wrote long ago in a poem entitled *Two Kinds of Intelligence*,

There are two kinds of intelligence: one acquired,
as a child in school memorizes facts and concepts

from books and from what the teacher says,
collecting information from the traditional sciences

as well as from the new sciences.

With such intelligence you rise in the world.

You get ranked ahead or behind others
in regard to your competence in retaining
information. You stroll with this intelligence
in and out of fields of knowledge, getting always

more

marks on your preserving tablets.

There is another kind of tablet, one
already completed and preserved inside you.

A spring overflowing its springbox. A freshness
in the center of the chest. This other intelligence
does not turn yellow or stagnate. It's fluid,
and it doesn't move from outside to inside
through conduits of plumbing-learning.

This second knowing is a fountainhead
from within you, moving out. (Rumi 2004,

p. 178)

How do intelligences get honored? How do students succeed in a counter-hegemonic social justice classroom and what is the measure of success? Because, for them, as we know, the letter grade on their transcript matters, and it would be naïve for critical pedagogues to not acknowledge this. Consider this from a Marxist perspective. Grades are often the equivalent of money. A student in a typical

Canadian university does not even have the opportunity to apply for most grants and bursaries without a certain average grade on her transcript. How then might critical pedagogues, many of whom reject having to reduce and deduce learning to a letter grade, engage this reality?

Or conversely how might a critical pedagogue manage an incident whereby the students protest the veracity of collaborative learning environments and course design if at the end of the semester, the professor still has control over the grades? There is an inevitable push/pull tension and slippery slope aspect to all of this that merits consideration. How does a social justice pedagogue collaborate in a manner that goes beyond “offering” student agency in the form of dialogue and the development of a classroom community in ways that are truly counter-hegemonic and meaningful? Is codesigning course syllabi and assignments sufficient? Is peer-marking an equitable approach to “power sharing”?

Students may start to “capitalize” on what they perceive as the lax or less structured approach to teaching and learning. Formal grievances, low teaching evaluations, assertive resistance, expressions of professor incompetency, and declarations of the teacher being a “fraud” are not uncommon in the counter-hegemonic classroom. In turn, professors often (over)react with “taking back” control, becoming martyred or disengaged, or reverting back to the very same traditional practices that they are attempting to disrupt and problematize.

What Now (and How)?

Social justice pedagogy is distinctly political and needs to be acknowledged as such. Teachers serve as agents of social change as do students. The hope is to alter current inequalities in society by equipping marginalized communities with strong future leaders who are able to succeed (Ayers et al. 2009). “The teacher’s role is to equip students with the knowledge, behavior, and skills needed to transform society into a place where social justice *can* exist” (p. 590). Social justice education shifts the focus from issues of cultural diversity (i.e., multicultural education) to issues of social justice, making social change and activism central to the vision of teaching and learning.

Social justice efforts must join with other levels of the educational system as an organization in the public and private sector and with the community to improve the educational opportunities and to address the current realities of students (Ayers et al. 2009; Malott and Porfilio 2011).

Positive mentorship, teacher training programs with a social justice focus, and participating in supportive communities of practice of like-minded social justice pedagogues can provide a platform for success. “I am surprised that you are doing all this pedagogical risk-taking given the current university administration” is a common utterance shared with social justice pedagogues. This kind of comment positions the scholar as a radical “other,” which on some level may be welcomed but on another level may leave her feeling quite alienated. Identifying all the “others” in your faculty or university and establishing communities of practice can help allay feelings of solidarity. Establishing transdisciplinary scholarship groups with a social justice bent and activist orientation can provide sources of support and new inspiration.

Enacting Social Justice in the Classroom

A social justice classroom should demonstrate a curriculum and classroom practice that is grounded in the lives of students, critical in its approach to the world and itself, hopeful, joyful, kind, and visionary, pro-justice, activist, academically engaging and rigorous, and culturally competent (Ayers et al. 2009). This next section will take a brief look at each of these core foci.

Know thy students first. Classroom practices need to be shaped around the lives of students, the classroom context, the educative aims of the practice, and the institution to construct learning experiences that articulate these (Breunig 2011). Writing exercises such as “I am” or “Dear (insert professor’s name here)” letters provide students with an early opportunity to share details about who they are, what they value, how they learn, and why they are there. Professors can begin the semester with this baseline knowledge and create lessons that align with students’ learning styles and needs. The social justice classroom and pedagogue need to be critical of the world and itself (including the institution and its constraints).

Professors need to acknowledge that the university as the contested site of critique is itself a space that reflects traditional norms of power and dominance and is also a site of privilege. There are many environments that are more conducive to counter-hegemonic resistance than the university (i.e., Greenpeace and Doctors Without Borders). In choosing the university, for both students and professors, you are choosing an environment that privileges the very concept of critical thinking, a privilege that is not afforded to everyone given the time and resource commitment. Approaching critique from what Kevin Kumashiro refers to as a pedagogy of “hope” and what Henry Giroux refers to as a pedagogy of “possibility” helps frame these conversations in the positive potential of social justice pedagogy, one that the above authors refer to as pro-justice. Patti Lather discusses her experiences with *getting lost* and being in a stuck place and then *getting found* in a cycle, falling in and out of hope (with moments of despair) in practicing social justice pedagogy in the postsecondary classroom.

Linda Keesing-Styles cautions against establishing a set of recipes for praxis. “Why do students leave the classroom in large lectures when the professor introduces an experiential activity to complement the content and to address the various learning styles of the students in the room?” Media literacy, experiential activities, case studies, guest lectures, creative writing exercises, performing curriculum, group work, “unpacking” bias and privilege activities, student-led initiatives, community-based service learning, self- and peer-marking, and hegemony treasure hunts are often met with student skepticism and resistance. “I left the room because you stopped teaching content. You were done with the powerpoint lecture” is a refrain often heard in the experiential social justice classroom. How do social justice pedagogues maintain engagement and reinforce that experiential activity is content? As mentioned above, attention to purposeful and intentional activities rather than just an activity for its own sake is important. Given students’ previous preparation as silent, passive, seated recipients of knowledge, what can professors convey about the importance of connecting meaningful

activities to theory? How can professors adopt praxes that are relevant, engaging, additive, and rigorous? “Will we be marked on this?” is something that is often heard in response to embodied activity engagement? Students have been trained to write down the powerpoint text and to memorize and convey understanding of that key content, but what should they do with these movement-oriented, group praxes? The professor holds a responsibility to convey the what, how, and why of purposeful social justice activities and also needs to be aware when too much activity is too much activity. Students may begin to rote act and respond, “Are we reflecting and journaling again? I am so tired of all this ‘think-pair-share’ activity but at least I now know what the teacher is looking for and how to deliver it.”

Most cultural competency initiatives focus on developing the interpersonal skills needed to understand, work with, and serve culturally diverse students. The term social justice competency provides a more expansive view of this construct, focusing on competencies beyond cultural ones, including socioeconomic class, sexual orientation, gender identity, ability, religion, and national origin, among others. Developing social justice competency starts with the professor identifying the ways in which positionality, biases, preconceived notions about pedagogy, previous training, the university “climate,” and student composition impact how the professor herself approaches social justice classroom praxis. “What is taught?” “How is it taught?” and “What is left out?” are some preliminary questions that merit exploration. It is naïve to assume that the social justice classroom is an objective or safe space. Just naming it as such does not make it so. Social justice pedagogy is pedagogical risk-taking and involves some personal exposure and vulnerability to enact.

Conclusion

There will forever be institutional constraints and student resistance when enacting social justice pedagogies in the postsecondary classroom. “Dancing” on the periphery of the institution

involves acknowledging the restraints and sometimes even embracing them while simultaneously engaging in praxes that offer counter-hegemonic possibilities of hope. Students have ample classroom experiences with being submissive, silent, passive, and dismissed. They also have ample messages that convey despair, bullying, and activist aggression. Students have classroom experiences that leave them feeling “stupid” or “impostors” of the very environment that is meant to be a site for learning and growth. The positive potential of the pro-justice postsecondary classroom, one that demonstrates in praxis, the very concepts that it theoretically purports, offers professors and students with a unique opportunity to engage the theory of the course with their experiences in the course, helping to bridge the gap between *what* is taught and *how* it is taught. The effort is worth it in the end.

Critical Education and Digital Cultures

Jeremy Knox
University of Edinburgh, Edinburgh, Scotland,
UK

Introduction

With the increasing uptake of digital technologies in many facets of education, perspectives from the study of technology and culture have proved to be rich and productive ways of understanding the qualities and trajectories of this emerging area. Nevertheless, such cultural concerns remain largely on the fringes of educational practice and research, which has tended to focus exclusively on the idea of a developing human subject (Usher and Edwards 1994). This grounding in humanism has tended to overlook the influence of culture and technology on education, privileging instead orthodox ideas such as universalism (that all humans are essentially the same), autonomy (that we are capable of independent thought and action), and rational progress (that reasoned thinking, as the goal of education, drives human development). This deep-seated relationship to humanism has structured the contemporary project of education around the idea of largely uniform individuals, who are essentially separated

from the world around them. In such an arrangement, cultural diversities are rendered subordinate to a universal human commonality, and technologies are framed in the simplistic role of “tools,” merely enhancing, or not, the intentions of their human users.

The perspectives of digital culture offer two principal and interrelated ways of thinking differently about education: the diversity, nuance, and strangeness of culture, as opposed to the rational universalism of education, combined with useful perspectives from the philosophy and theory of technology, which are able to account for more complex notions of our relationships with the digital. Where education has adhered to its humanist foundations, technology tends to be framed in terms of the benefits or disadvantages it brings to teaching and learning practices, rather than attempting to explore *how* technologies might be used, valued, imagined, or represented by those involved. This is the significance of cultural studies' approaches: to bring other disciplinary insights to bear on education that are motivated less by agendas of improvement and are more concerned with understanding how social life is constructed and lived. This cultural concern draws from a rich history of social and political theory and philosophy, no less the *critical theory*, associated with “The Frankfurt School,” which emphasizes the analysis and critique of dominant ideologies and understandings. This shifts educational concerns away from the habitual fixation on the growth and development of the individual, toward a richer engagement with the ways education is shaped and practiced with and through the digital.

The other crucial aspect of cultural perspectives outlined here is the decentering of the individual as the exclusive source and end of educational concerns, a perspective often associated with poststructuralism. The humanist foundation of education severely limits our understanding of technology, precisely because the essence of the human *subject* is preserved as a bounded entity, entirely separate from the outside world of *objects*: technologies, environments, and other “nonhuman” things. Within this framework, technology tends to be understood in terms of an

outside intervention, something that “impacts” on a preexisting, non-digital, and “natural” kind of education. Where “human” and “technology” are positioned as separate and distinct, with their own inherent characteristics, their interaction can only be understood along *determinist* lines. In other words, either human agency drives technological change as “social determinism” or “uses determinism” or digital devices define and govern how people use them, termed “technological determinism” (Dahlberg 2004).

The first position surfaces in the widespread claim that technology is “simply a tool” for pre-determined educational aims (either of the individual or society), while the second tends to manifest in pessimistic narratives of the degradation of authentic education, driven and defined by the increasing pervasion of digital technologies. While neither position provides the conceptual means to understand the complex relations at play, a digital cultures’ perspective looks beyond the orthodox domains of education to ideas of technology’s entrenched and co-constitutive connections with human life. The following will account for *education and digital cultures* in three interrelated phases: cybercultures, community cultures, and algorithmic cultures. These phases are suggested to be chronological, but not in the sense that any one of them necessarily concludes, rather that particular ideas become dominant, and less so, over time.

Cybercultures

This phase is associated with an increased interest in and awareness of ideas developed in cybernetics and diffused through science fiction literature and film. Key here is the figure of the cyborg, an augmented human being that represents both a cybernetic arrangement of the blurred boundaries between the living and the machinic and a disturbing sci-fi vision of the consequences of increasing technological development. Donna Haraway’s cyborg manifesto (1991) and N. Katherine Hayles’s study of posthumanism (1999) are seminal works in this area, shaping a variety of feminist, sociological, and cultural studies of science and technology. The burgeoning discipline of Internet Studies made influential

connections between this theory and the technologies of the web, perhaps demonstrated most overtly in the *Cybercultures Reader* (Bell and Kennedy 2000).

A key term at this time was cyberspace, a term coined by William Gibson in the cult sci-fi novel *Neuromancer* (1984), which encapsulated a specifically spatial understanding of ideas from cybernetics, often framing web technologies and services in terms of “other worldly” and “virtual” domains. These ideas were also a product of the counterculture origins of many web communities, most notably the Whole Earth ‘Lectronic Link (known as “the WELL”), associated with utopian visions of alternative and emancipatory online spaces. Significant research in this area foregrounded issues of presence, identity, and sexuality, often studying multiuser domains (MUDs), and later virtual worlds like Second Life, proposing the digital as a fertile social space, within which alternative, often unconventional, “selves” could be fostered. This work emphasized “sociocultural” perspectives on technology, as opposed to a dominant “technical” understanding, that merely sought to understand technology by understanding how it worked. In order to study the social uses of technology, more established anthropological approaches were rearticulated, perhaps most notably as “virtual ethnography” (Hine 2000), signaling a need for methodological means appropriate to the exploration of these new cultural domains.

It is through the lens of such work that the broader influences and practices of educational research, under the banner of labels like “e-learning” and “online education,” can be understood critically. Cybercultures thus frame the early enthusiasm for digital education as the promise of the “virtual,” both in terms of space and identity. Advocacy of the “virtual environment” is often grounded in the idea of an alternative domain, capable of fostering individual aptitudes and characteristics, unfettered by the constraints of the physical body or the restrictions of the institution. Correspondingly, the avatars and other virtual personae adopted for such educational pursuits are sometimes considered to imbue the student user with tangible possibilities to escape the

limitations and barriers of physical copresence and embodiment.

These underlying ideas can be traced to the counterculture perspectives of the early web, positioning online spaces as foundationally radical and noninstitutional, and online presence as problematically “of the mind” as opposed to the body, redolent of a Cartesian dualism long dismissed in education. A cybercultures’ perspective thus highlights the need for robust critical approaches in order to counter tendencies for the kind of utopic and emancipatory accounts that often pervade the field of e-learning. This work traces the nuances and actualities of space and place, movement, and stasis in educational uses of the web (Bayne 2004a) and attests to the persistence of the body, and the way it is reconfigured through the digital, rather than simply negated or denied (Bayne 2004b).

The trend for the cyber-prefix has declined, in the wake of a decreasing fascination with the digital as radically other, particularly where technology has become more pervasive. Digital Education has largely shifted away from the phase of cybercultures, toward the view of an educational world in which technology is more firmly embedded, but importantly also more subservient to its human users. In other words, where the cyborg signaled a frightening oscillation between the determinist stances of enhancement on the one hand and a loss of control on the other, the next phase of education and digital cultures reveals a pacification and instrumentalization of technology for predefined social ends.

Community Cultures

The growing social dimensions of virtual worlds were aligned with a broader increase in the capacity for communication and interaction on the web. It is this trajectory that ushers in the phase of *community cultures*. Following seminal works such as Howard Rheingold’s *The Virtual Community* (2000), inspired by experiences of the WELL, work in Internet Studies has strived to make the case for rich and complex social phenomena enacted through the web. Countering more established views of the paucity of online

interaction, and a lack of the intensity and depth assumed in so-called “face-to-face” communication, this research tended to emphasize the dialogue, sharing, exchange, and kinship practices taking place between members of online discussion groups and gatherings. Rather than otherworldly or strange, here the online is warm, friendly, and communal. However, importantly, this stance nudged web technology into the role of instrument, a passive device that serves the aims of its users, and simply facilitates the enhancement of an exclusively human drive for social interaction.

The idea of technical capacity was captured in the notion of “Web 2.0,” a term often used to refer to an increasing emphasis on user-generated content and interactivity found on the web. Thus, in this phase of more mainstream use of the Internet, the technologies of the web tended to be framed in more productive and beneficial terms, as services which acted to support and enhance conventional social life, as opposed to the narratives of alternative “otherworldliness.” Here the concept of the “network” comes to the fore, replacing the spatial inflections of “virtuality” with a much more functional idea of web technology: the invisible means to connect people. Social networks such as MySpace, Facebook, and Twitter were identified as intense sites of contemporary community culture and became the focus of dedicated research, primarily on the grounds of the propensity for public interaction rather than the features of the technology itself.

This privileging of participation over consumption neatly reflected the long-standing educational grounding in dialogue, as well as more recent trends that shifted emphasis away from teachers and toward students, and which sought to understand learning as the social construction of knowledge, rather than individual internalization. Mirroring the mainstreaming of the web, educational institutions were also adopting more digital and networked technologies, which began to move from the fringes of educational provision to more typical institutional offerings. The idea that technology simply provided resource artifacts for teaching and

learning began to be replaced by the idea that technology provided the means for dialogue and communication.

The field of education and technology is often recast around these changing perspectives, perhaps most strikingly in “networked learning,” signaling both the instrumentalism of technology and the reorganization of education around the learning of the individual. In these ways, the communicative potentials of the network are frequently positioned as the solution to the hierarchies, inequalities, and inaccessibilities of the institution. Thus, rather than “virtual” or “otherworldly space,” technology becomes anti-institutional and emancipatory in its capacity to *facilitate* and *enhance* those traits already present in society.

However, bound up in this shift has been a naturalization of “social learning” and a concealment of technology itself, such that learning through communicative networks is often positioned as synonymous with our innate being. The notion of networked learning reaches its zenith in the proposed learning theory of connectivism, which frames the processes of learning as quite literally those of the network. The value of a digital cultures’ perspective is to reveal the broader influences, assumptions, and trajectories bound up in the drive for participative and networked e-learning communities. Such perspectives can account for how the ideas of “socially networked learning” have been constructed, rather than assuming them to be the unquestionable facts of our contemporary educational project.

Ultimately, the centering of community in education problematically positions web technology as the passive instrument of our predetermined educational aims. This overlooks the powerful economic and ideological forces that underpin and shape the technology industry. The drive for technologies that facilitate our “community learning” has simultaneously embroiled education in a Silicon Valley culture, motivated by data acquisition and profit. In this sense, “community learning” can be understood, not simply as the baseline of our natural educational disposition, but rather as a particular construction of the educational

project that has been significantly influenced by both cultural and industrial facets of the web.

Algorithmic Cultures

In response to an exclusive focus on community and culture that renders technology passive and invisible, emerging areas of research are attempting to account for the influence of technology itself and also more nuanced understandings of the co-constitutive relations between humans and nonhumans in education. *Algorithmic cultures* in education can be understood as one such area, focusing specifically on the operation of web algorithms, and the ways these automated, non-human agents influence contemporary educational practices.

This phase draws from a growing interest in the field of Internet Studies, which is concerned with tracing the ways culture is not only being shaped by its human constituents but also by the pervasive algorithms of the web that are increasingly involved in the arranging, cataloging, and ranking of people, places, and knowledge. Well-known examples include the Google search algorithm, which has become hugely influential in prioritizing and privileging certain knowledge, and the Amazon recommendation algorithm, which has significant sway over our buying habits. Alongside such everyday examples, and intentionally hidden from our gaze and attention, algorithms are becoming increasingly ubiquitous actors in the global economy, as well as our social and material worlds.

Critical research, sometimes associated with the burgeoning field of Software Studies, has sought to examine and question such algorithms as guarantors of objectivity, authority, and efficiency. This work is focused on highlighting the assumptions and rules already encoded into algorithmic operation, such that they are considered always political and always biased. From this perspective, algorithms *produce* worlds rather than objectively account for them and are considered as manifestations of power. Questions around what kind of individuals and societies are advantaged or excluded through algorithms become crucial here.

Moreover, because these systems often enmesh automated, individual, and communal decision making in highly complex and usually hidden ways, the results cannot easily be reduced to the intentional agency of any one identifiable human person (whether user or programmer) or non-human algorithm. It is precisely this orientation that has sometimes drawn researchers to theories of distributed and relational agency, such as actor-network theory, or sociomaterial theory, in order to account for the complex layers of activity involved.

Where education has embraced digital networks, the practice of teaching and learning can be understood to be increasingly entangled in algorithmic operations. Such automated processes are highly appealing to education, which viewed from the perspective of neoliberalism tends to privilege objective logic, precision, and transparency as routes to further efficiency, productivity, and accountability. It is notable that algorithms, assumed to provide objectivity and exactitude, are frequently used in areas of high risk and security, and this is precisely where the most prominent example can be found in education: the use of the Turnitin plagiarism detection service at the point of assessment.

However, a digital cultures' perspective provides the means to critically engage with this developing educational trend, rather than assume the transparency and necessity of automation. This critical lens has the capacity to reveal not only the range of assumptions and limitations that are built-in to the algorithmic operations of plagiarism detection but also the broader cultural and political tendencies that are enfolded in the drive for efficiency that pervades institutional education. Looking to the future of education and digital cultures, work is turning to the ways that algorithms not only censor educational content but also work to construct learning subjects, academic practices, and institutional strategies. Perhaps most importantly, this signals a shift away from the centrality of individual or social concerns in education and toward the complex relations between the human and nonhuman

agencies that proliferate in our digitally networked educational activities.

Conclusion

This entry has described three interrelated phases of digital cultures in education, with a view to highlighting some of the key critical themes revealed through the radically interdisciplinary perspectives of cultural studies. *Cybercultures* described how early understandings of the web, often influenced by cybernetic theory and sci-fi literature and film, shaped the ways educational possibilities were presented, often in the form of "virtual worlds." Critical perspectives highlighted the need for nuanced understandings of space, place, and embodiment as digital technology increasingly pervades educational provision. *Community cultures* described the shift toward mainstream Internet use, and the rise of social networks, as well as communicative and participatory online spaces in education. Critical considerations highlighted the political and economic forces enfolded in the rise of networked learning and the broader issues of data acquisition and profit underpinning the technology industry. *Algorithmic cultures* described a current phase in which automated computer operations process data in such a way as to significantly shape the contemporary categorizing and privileging of knowledge, places, and people. Critical perspectives on this "cultural work" included the questioning of objectivity and authority assumed of algorithms and sought to emphasize the ways that educational institutions, practices, and subjects are constructed through these highly complex computational routines.

Each of these phases reveals a particular view of the relationship between human beings and technology, and these orientations are central to understanding the critical dimensions involved. *Cybercultures* tended to emphasize a radical otherness to technology, whether foreign or fetish, such that educational possibilities shifted from utopic promises of virtual worlds to dystopic renditions of human development under threat from machines. *Community cultures* mark a shift in the

framing of technology, replacing strangeness and “virtuality” with the functionality of the social network, reflecting “social determinism.” Here technology becomes subservient to the communicative needs of education (and society), becoming more invisible itself as the mere channels and conduits of socially constructed knowledge. In the third phase, *algorithmic cultures* signal a shift away from exclusively social and human concerns and the attempt to account for the non-human agency of technology in educational practices. Rather than technology being framed as simply the passive instrument of predefined educational aims, here the algorithm represents a much more complex relationship between humans and nonhumans in education, pointing toward an increased entanglement of agencies in the production of knowledge and culture.

Critical Education and Postcolonialism

Vanessa de Oliveira Andreotti¹ and

²University of Sao Paulo, Sao Paulo, Brazil

Introduction

Educators and scholars use the phrase “critical education” to refer to many different forms of critique that may be similar to or incommensurable with each other. Even when referring to postcolonial orientations to critical education, there are still a variety of perspectives grounded on

different interpretations of criticality and of postcolonialism itself. Part of the problem with trying to disentangle similarities and incommensurabilities of perspectives is that the dominant academic culture creates aspirations for universal forms of consensus on definitions and “ways forward.” When these aspirations are at work, differences are perceived as obstacles to what is perceived as “progress.” However, from a different perspective, working through incommensurabilities, paradoxes, complexities, and contradictions – working with and through difference – can also be seen as essential and generative in terms of intellectual depth and accountability. This is already an illustration of a form of postcolonial critical orientation that works against the grain of naturalized Enlightenment desires for mastery and intellectual normativity that ground the dominant academic culture.

In this entry, different types of critique, of postcolonial studies, and of critical education and implications for educational research, policy, and practice are outlined. Strategic and performative distinctions are established that aim to amplify differences and nuances between intellectual communities that are generally glossed over. This is done in order to create vocabularies that illuminate both what is visible and what has been absent in recurrent discussions. The distinctions presented here are informed by postcolonial analyses; however, they are educational and performative, rather than normative or representational: they do not aim to dictate what really exists, what one should believe in or the correct path one should take. The distinctions are instead created to displace normalized discussions and imaginaries, provoke new responses, and prompt further critiques (including critiques of the distinctions themselves).

Different Types of Critique

When establishing strategic distinctions, it is useful to use analogies to decontextualize the dominant ways in which a topic is usually approached. Taking art as an analogy for critique can help in

developing new vocabularies to talk about the relationship between knowledge, reality, and representation. In this entry, a strategic distinction between three types of art is proposed: “decorative art,” “naming art,” and “vomiting art.” Decorative art aims to affirm existing imaginaries and discourses by creating something that fits the definition, chains of affect, images, and social scripts around the concept of beauty that is normalized within a particular community (e.g., Rembrandt, Remer, and Ibsen). Naming art aims to expose what a particular normalization leaves out, what is foreclosed, taking people to the edge of what is familiar (e.g., Escher, Velazquez, and Boal). Vomiting art aims to explode and externalize the debris of established/familiar frames of reference in an attempt to liberate its audience for something new, but undefined – aiming to push spectators over the edge, into an abyss beyond the securities of representation (e.g., Kantor, Duchamp, and Schechner).

Reading critique through these analogies, a few different types of critique emerge within and between the intersections of the distinctions. For example, there are decorative critiques that aim to identify and solve problems through established and naturalized parameters of what is possible and desirable, without going beyond these parameters. These types of critique do not problematize the relationship between representation and reality, assuming that, for example, the concept of beauty is universal, but only a selected few are educated to appreciate it or that everyone wants inclusion into a dominant system. A neutral and universal position of the critic is assumed as a point of departure.

There are naming critiques that trace the construction of what is perceived as normal and natural, showing the “aporias” (the hidden metaphysical choices) of (dominant) discourses and practices. They show that dominant notions of beauty, of reality, of goodness, and of the way forward are socially, culturally, and historically situated and that their social production and mobilization are mediated by relations of power and the erasure of alternatives. These critiques problematize the relationship between representation

and reality; however they do it to different extents and with different purposes.

For example, there are types of critique that selectively choose what needs to be deconstructed and often propose ways forward that substitute dominant assumptions about what is real and ideal with assumptions that do not problematize the relationship between representation and reality. Some aim to emancipate subjects by affording agency to representation, often relying on a fixed conceptualization of subjectivity as conscious, transparent, and stable. Other types of naming critique propose that deconstruction should be applied not only to the critique of dominant discourses but to all discourses, particularly discourses proposing alternatives to what is taken to be dominant. This type of naming critique questions the centrality of agency, the stability of subjectivities, and the possibility of representation. Naming critiques do not assume the neutrality of the critic, but do not necessarily open themselves to self-reflexive criticism either.

There are questions as to whether vomiting critiques can actually be performed through logic alone. This kind of critique works beyond the realm of consciousness and logical and rational intelligibility; therefore, if its purpose is to shatter existing frames of reference and not to substitute them with alternatives, it cannot simply work through established referents. In this sense, it shows that naming critiques that rely on logic alone are generally circular: critics have to use the very referents they criticize to make the points they want to make (working within the realm of what is intelligible). However, this limitation is extremely important as it invites readers beyond it, by showing the insufficiency and indispensability of both art and logic, as is illustrated in the next sections.

Different Types of Postcolonial Studies

Postcolonial studies are an interdisciplinary field that originally emerged in literary, cultural, and area studies. It focuses on analyses of and resistance to different past and ongoing forms of colonialism and imperialism deeply embedded in

normalized imaginaries and modern institutions. The field does not offer a unified and coherent theory as such, but a set of questions (Gandhi 1998) formulated to constantly unsettle systemic processes that create and sustain cultural hierarchies, racialized borders, unequal divisions of resources and labor, as well as the definitions of value and merit of cultures and forms of identities and subjectivities. Postcolonialism challenges discourses of assimilation and the ethics of care and responsibility “for the Other” at work in liberal humanist discourses, proposing, instead an ethic of answerability that emphasizes the importance of keeping past and present injustices firmly in view. However, analyses and proposals for how that should happen take different forms. A distinction between two different orientations within postcolonial studies is useful for identifying different types of naming critique in practice.

A Marxist/neo-Marxist orientation deconstructs the production of subjectivities by dominant/hegemonic colonial discourses perceived as a form of false consciousness that affect both colonizers (who believe in the illusion of their supremacy and use it to justify unequal power and distribution) and the colonized (who internalize their oppression by believing in their inferiority). Through structural analyses, power is conceptualized as something that is exercised as force and coercion over less powerful and exploited populations. Liberation (from false consciousness) is equated with historical agency, self-representation, and decolonization as the right to have one’s voice heard in democratic processes. Therefore, through human rational agency, and the pursuit of truth, the oppressed should be able to counter and transcend oppressive forces and achieve a larger and decolonized humanist utopia of freedom and expression through the resistance to and subversion of colonial forces, discourses, and institutions. In this sense, this orientation aims to transform the Eurocentrism of Western humanism to include the marginalized, oppressed, and excluded through their emancipation, empowerment, voice, and agency. The role of the critic is to launch an intellectually normative analysis that reveals the structural injustices of the dominant

system that can be corrected through a commitment to creating spaces where the oppressed can speak and be heard in order to be genuinely included in the dominant system. The works of Young (2003), Guha (1997), and Parry (2015) take this direction.

The orientation informed by poststructuralism and (Lacanian) psychoanalysis complexifies the relationship between the colonizers and the colonized by focusing on the intricate relationship between knowledge, power, representation, and claims of truth. Its starting point is the impossibility of decolonizing humanism, as humanist tenets are traced back to a modern grammar that cannot be disentangled from the ongoing violences of colonialism and imperialism. This orientation exposes aporias at work in any discourse, including hegemonic and counter-hegemonic discourses, emphasizing the impossibility of launching a critique without being implicated in it. This emphasis on the complicity of the critic in that which is critiqued forces the critic to create other languages and subject positions to work with paradoxical relations. As emancipation, agency, and essentialism are problematized and an uncontaminated resistance becomes impossible in this orientation, the imagined way forward is the opening of new possibilities toward what is unimaginable from the “edge” of normalized imaginaries. An illustration of this is the idea of “an uncoercive relationship towards the Other of Western humanism” (Gandhi 1998) that requires an ethical stance of (not) knowing for an ethical imperative toward the Other to emerge, before will (Spivak 2004). This implies a willingness to work through double binds and a hyper-self-reflexive deconstructive stance of learning to learn/work without guarantees or the affirmation of one’s innocence (*ibid*) and the opening of the imagination to a form of ethical imperative that precedes rational thought and intellectual choice. This orientation emphasizes the difficulties of transforming inequalities while inhabiting and being conditioned by modern systems, discourses, and institutions that conceal the violences that subsidize their very existence. Authors that take this direction, like Spivak (1999), Bhabha (1994), and

Said (1993), also contingently make use of Marxist critiques while being critical of aspects of it.

Different Types of Critical Education

The way one defines critical education depends on the way one defines the problem to be critiqued. The fact that “critical thinking” has become an all-encompassing term also complicates discussions, as educators may believe that because they are using similar terms, they are talking about the same thing. In order to clarify different uses, a distinction between three problem spaces of critique is proposed in this entry: soft reform of modernity, radical reform of modernity, and modernity beyond reform.

The “soft reform of modernity” problem space sees modernity as inherently benevolent and sustainable in its overall direction of engineering a world grounded on science and technology that can work for everyone’s well-being. Problems of inequality are perceived as emerging from a lack of modernity found in social groups considered to be behind in terms of human evolution, national progress, or international development. Therefore more modernity is prescribed, often through education, as a cure for these perceived problems. Since modernity is portrayed as a universal critical project that is constantly moving forward, when critical education is evoked as a prescribed strategy within this problem space, it often refers to problem-solving geared toward liberal humanist ideals of assimilation and social mobility/insertion within modern societies perceived as inherently benevolent and desirable.

The “radical reform of modernity” problem space sees modernity as severely limited in its capacity to fulfill its promise of universal well-being, but still recuperable/fixable if more voices are included in deliberations and if excluded people can exercise their agency in democratic processes. Problems of inequality are perceived as emerging in the imperialistic and colonial historical roots of modernity and in ongoing Eurocentric practices of modern institutions and relationships. Therefore, a radical transformation of modernity is necessary to counter historical

legacies and persistent hegemonic tendencies. Critical education is perceived as the means through which this transformation is to be achieved. Criticality is conceptualized as an awareness of the social and historical mechanisms that create inequalities in power, representation, voice, participation, and access to social mobility. Humanism, grounded on a Eurocentric notion of the human, is perceived to be unjust and may be corrected through the inclusion of previously excluded humans. Critical self-reflection and the notion of praxis are used to emphasize the need for self-transformation and the dynamic complementarity of theory and practice.

The “modernity beyond reform” problem space characterizes modernity as inherently harmful, unsustainable, and irresponsible in its illusionary promises as its expansion is inevitably subsidized by “outsourced” violence and exploitation, e.g., having most people in the planet join the middle class would exceed the capacity of the planet to sustain already stretched levels of consumption and pollution. From this analysis of the problem, a few competing possibilities emerge. Some of these possibilities include walking out from dominant systems and institutions (e.g., the deschooling movement), investing in the creation of alternatives (e.g., Gaia education), hacking the system from within, or hospicing the system in order to learn from its mistakes and make only different mistakes in the future (see Andreotti et al. 2015). Critical education within this problem space generally focuses either on delinking from modernity and creating/finding more sustainable alternatives and/or learning from modernity’s mistakes. Criticality is associated with challenging overconsumption, exploitation, environmental destruction, and the quest for status, prestige, identity, influence, and affluence as a universal goal for existence.

Soft reform attributes positivity and universality to the dominant knowledge system, and the same positivity is denied to anything deemed to be outside of this system. Radical reform attributes a level of negativity to the dominant system and positivity to what was excluded and proposes to replace the system’s negativity with the positivity of what was previously excluded. Beyond reform either attributes negativity to the dominant system and

positivity to what is Other to it or refuses to work with the positive/negative binary attributing positivity to this refusal and seeing it as a productive space. In this sense, soft reform sustains a form of hope for the continuation of the current system as it is. Radical reform sustains a form of hope for the expansion and adjustment of the current system. Finally, beyond reform sustains either paralyzing hopelessness, evangelical hope placed in an articulated solution, messianic hope of something inevitable to come, or hope beyond hope of something new that cannot be defined a priori.

While soft reform critical education can be associated with decorative types of art/critique, radical and beyond reform forms of critical education require “naming” things that the soft reform problem space tends to erase. However, while radical reform naming critiques have epistemological dominance as a priority, and beyond reform critiques have ontological dominance as a priority, it is only “vomiting art” that most effectively exposes pre-ontological/metaphysical dominance (where “ontological” refers to beings that exist, metaphysical refers to what brings beings into existence). Marxist/neo-Marxist orientation of postcolonial studies can be mapped onto radical reform, while the poststructuralist orientation operates at the limits between radical reform and beyond reform.

Implications for Educational Research, Policy, and Practice

The distinctions presented so far have deep implications for research policy and practice. To conclude this entry, an outline of some of the implications of different types of critical education is presented, as seen through a (general) postcolonial critique.

Typical soft reform research questions tend to see the status quo as inherently benevolent and universally desirable, while seeing the Other as deficient or lacking. Questions are formulated in instrumental ways with a view to support modern institutions to provide the Other with access to the dominant system as a remedy for his/her lack. The

general orientation for questions is: how can education strategies for the marginalized or excluded be more effective in bringing them up to our standards? In terms of policy, “Education for All” and OECD’s initiatives toward a global standardized curriculum are clear illustrations of the attempt to address deficiencies by affirming an unquestioned and unexamined universal norm. As far as practice is concerned, the search for greater efficiency and (economic and entrepreneurial) innovation through the application of (problem-solving) “critical competencies” also attest to the perceived need to prescribe more modernity to the problems that modernity has created.

Typical radical reform research questions aim to bridge the gap between dominant knowledge systems and the knowledge of the excluded. Empowerment is conceptualized as access to dominant modes of education, knowledge production, and participation. Expanding access is also perceived as an opportunity to transform dominant institutions from within. Therefore, the general orientation includes research questions such as: How does the existing system exclude and marginalize Others? How can we transform the existing system to accommodate the marginalized and excluded? Policies aim to question the universality of Eurocentric knowledges and integrate formerly excluded knowledges and perspectives into the mainstream system. In terms of practice, in different ways, ideology critique is prioritized in exposing the injustice of the dominant system and revealing the correction that the system needs to undergo in order to become fairer.

Typical beyond reform research questions aim to experiment with different systems of knowledge production and ways of being. The search for and experimentation with alternatives is perceived as an urgent educational task, including alternative ways to approach alternatives (Sousa Santos 2007). The general orientation includes research questions like: How have our imaginaries been limited by modernity? How can we imagine knowing and being beyond the rationality, logocentrism, and anthropocentrism of modernity? Policies are perceived precisely as a manifestation of modernistic rationality essential to modern institutions; therefore alternatives to

policy are also a priority in terms of imagining other forms of relationships, collective organizing, and knowledge production and distribution. Drawing on postcolonial analyses, one way of imagining critical education is to conceptualize it as involving two processes that are necessary to open up the imagination to something new and undefined. The first process involves constantly provoking ourselves to perceive the limitations of modernist forms of knowing and being, while not rejecting them wholesale. The second process, which happens in parallel to the first, involves decentering and disarming the Western subject and displacing the obsessive need for rationality and control in order to reignite a pre-ontological visceral (hence prerational) sense of horizontal entanglement with everything and everyone in the world that may, existentially, rearrange desires away from the violences of modernity.

In conclusion, there are two different perceptions of the problem that critical education needs to solve. In soft and radical reform orientations, the problem is perceived as ignorance (as a deficit) that can be addressed and compensated with more knowledge of universal worth (however it is defined). In the beyond reform orientation presented here (and this is only one interpretation), the problem is perceived as one of denial of the contradictions and violences of modernity, expressed as an unexamined attachment to its promises, comforts, and perceived securities. From this perspective, critical education needs to bypass ego-logical defenses in order to support an uncoercive reorganization of affect away from the modernist tenets of separability between elements, bodies, and modes of existence.

Critical Gender Studies as a Lens on Education and Schooling

Heather Greenhalgh-Spencer
Texas Tech University, Lubbock, TX, USA

Synonyms

[Gender](#); [Postfeminism](#); [Schooling](#)

Introduction

According to *US News and World Report* (2014), women in the USA are surpassing men in earning bachelor's degrees as well as graduate degrees. Women are also making gains in fields traditionally dominated by men. The same report notes that,

"Today, women in their early 30s are just as likely to be doctors or lawyers as they are to be teachers or secretaries" (U.S. News 2014). This phenomenon is not just found in the USA. The *Sydney Morning Herald* (2013) reports that, in Australia, women get more bachelors' and graduate degrees than men. *The Guardian* (2013) reports that, within the UK, not only do women receive more degrees – at all levels – than men, but there are some universities where women outnumber the men 2/1. The MacMillan Center, at Yale University, shows that, *globally*, women are more educated than men MacMillan Center Report (2014). What these reports also reveal is that women still make less than men in general, and they get paid less for doing the same job with the same skill level. Still, one can see how it would be easy to decide that feminism was not needed any more. These statistics validate postfeminist discourses where, supposedly, women are now empowered – maybe even too empowered vis-a-vis men – and any disparity is down to personal choice. Postfeminist discourses prompt the question: Does gender matter anymore?

This entry is a resounding "yes" to that question. Gender still matters; it still matters in schools and other educational spaces. This entry acts as both a survey of remarkable current research that draws on gender as a lens to understand experiences of schooling and education and an argument that gender is still important in education and that postfeminist discourses need to be critiqued and examined more closely. In this entry, critical gender studies is used as a lens for exploring and analyzing the ways that gender is meaningful and shapes experience in schools and other educational spaces.

Critical gender studies, as a theoretical framework, foreground the ways that gender is meaningful for understanding ideology, history, practice, forms of intervention, and oppression, for making the world intelligible, and for informing policy. This entry draws on critical gender studies as a frame for understanding school and education. The school overlaps with, but is also distinct from, education. Critical gender studies illuminate the ways that gender matters in school: the practices of schooling, the curriculum, pedagogy, and interactions between teachers, staff, administrators, parents, and students.

Critical gender studies also invigorates discussions on education as a practice that happens both inside and outside of schooling spaces; as something that is consciously taught by parents, mentors, teachers, politicians, the media, and also something that is subtly coerced by society. This entry highlights some of the new and invigorating scholarship in critical gender studies and explores the ways this scholarship guides toward thinking and practicing differently in regard to schooling spaces, praxis, curriculum, education, and identity-making.

In order to explore research that focuses on gender and educative experiences that happen outside of the school building, this entry first delves into some of the research on gender and informal educative spaces. Next, the entry highlights research on the formal schooling experience in general. Finally, the entry takes a more discrete look at research on gender and the profession of education: teachers and principals. The entry concludes with a brief analysis of the ways this current scholarship pushes against postfeminist discourses.

Informal Educative Spaces

A critical gender studies lens reveals the importance of gender in all places with educative value. Even in more informal learning spaces, gender matters, and a gendered lens reveals the ways that gender shapes identity, beliefs, policies, and practices. For example, Ford (2013) talks about using digital spaces to teach citizenship and organize citizenship activities. She focuses on bringing a black queer lens to citizenship teaching and activism. Ford foregrounds the ways that thinking through citizenship using a black queer lens for exploration allows her to reveal heteronormative and traditional hierarchies, even in activist places that are aiming for inclusivity. Even though Ford's research does not take place in a formal schooling environment, she writes about the educative experiences that happen online. These online experiences teach about the ways that race and gender still shape one's access to power, resources, and a sense of belonging.

Like Ford, other scholars also study the importance of gender in informal learning spaces.

Hughes et al. (2013), for example, study the importance of gender and the experience of summer STEM learning camps. Hughes et al. examined how these camps influenced girls and their sense of efficacy in and desire toward STEM careers. Some of the camps were single-sex and others were co-ed. The single-sex experience was not important for girls' sense of efficacy or identification with STEM careers. What proved to be meaningful was the type of pedagogy that was involved. Pedagogy that focused on identity, empowerment, and normalizing participation among both girls and boys was most meaningful. The type of pedagogy, and the aim to normalize STEM as part of a female as well as male identity, was more important for girls than for boys. Students' reaction to pedagogy was shaped by gender.

A critical gendered lens also becomes powerful when analyzing the issue of climate change and environmental damage. As I have noted elsewhere, climate change and environmental damage have a disproportionate effect on women (Greenhalgh-Spencer 2015). In addition to using gender as a lens to think about the effects of climate change, gender – or gender studies – can also be used to prompt critical analysis of ways to combat climate change and environmental damage. Kaijser and Kronsell (2014) draw on the critical feminist philosophy and practice of intersectionality as a lens for educating toward greater climate change awareness and eco-interventions. Kaijser and Kronsell (2014) argue that it is the feminist practice of understanding intersectionality that guides their focus on localness: local change, local awareness, local education, and local activism. This focus on localness is contra a more patriarchal focus on a top-down development of policies on environmental damage and climate change. Embeddedness in the local pushes against patriarchal notions of capitalism.

Current research not only focuses on the importance of gender or a gendered lens in informal learning spaces but also highlights the importance of gender and a critical gender lens on the site of the school. Gender shapes access to resources, power, and the general experience of school.

Experiences of Schooling: Postfeminist Discourses

The experience of schooling, particularly in the West but also in other regions of the world, is influenced by a growing discourse of a postfeminist world. This postfeminist discourse links in with discourses validating neoliberal ideologies and practices to create a skepticism around the need to think about gender, and women's equality, any more. For example, Ringrose argues that a postfeminist discourse links into a discourse of the "failing boy." Ringrose argues that hysteria over "the failing boy" has supplanted any care for equality for women. She examines the ways these discourses re-center maleness, de-radicalize feminism, and re-center traditional notions of femininity in the schools – particularly in regard to STEM education but also in regard to narratives around test performance in schools. Ringrose argues that postfeminist discourses enable a validation of the lack of women in STEM, as well as a redirection of funding in schools away from women and in support of men. Postfeminist politics of schooling are recreating binaries and influencing schooling policies.

Dosekun (2015) furthers the argument that postfeminist discourses are harming girls and societies throughout the world by focusing on the deployment of postfeminist discourses in developing countries. Dosekun argues that postfeminist discourses are not just discourses in the West. They have infiltrated countries in the Global South. They have interpolated women outside of the "Western" context. The discourse of a postfeminist world influences policies around schooling as well as policies toward economic parity. Dosekun also makes the case that – as a larger concern of educating a global public – we need to critique postfeminist discourses on a global level. We need to push against postfeminist discourse that undermines pathways for girls and women to go to school and have access to equal resources.

Harris and Dobson (2015) make similar claims. Post-girl-power narratives and politics are reinstating patriarchy in countries both inside and outside of the G20. This discourse is infiltrating areas of schooling, media, and economic

policy and has real consequences for identity-making at all stages of life – but particularly in formative stages in school. In videos and textbooks, the idea that we have now reached parity and that gender no longer matters is validated and normalized. When girls fail to have opportunities, fail to have equal access to resources, and fail to "choose" STEM careers, this postfeminist narrative equates any such failures as the fault of individuals (usually the individual girls) rather than a failure of policy, ideology, and practice. Postfeminist discourses connect with neoliberalism to discount any need for policy intervention and activism, instead centering the idea of choice and individual responsibility for access to and enjoyment of resources and an equity of pathways toward learning and fulfillment in life.

Discourses around the STEM gap as an issue of "choice" become particularly problematic when we consider research by Archer et al. (2014) which shows that the STEM gap is a problem of discursive identity. Archer et al. show that there is an entrenched narrative of what a "STEM person" looks like. Discourses of masculinity link in with discourses of whiteness, ability, and middle-class social grouping in order to articulate the STEM practitioner as someone who is male, white, able-bodied, and middle class. If one does not fit into this nexus of categories, then one does not fit into STEM. Archer et al. convincingly argue that STEM pathways are not a matter of choice so much as a matter of identity connected with already established norms that favor white middle-class males. Their research pushes against postfeminist discourses that re-center maleness and validate the idea that disparity and inequality are a matter of personal responsibility.

A critical gender studies lens not only counters postfeminist discourses, it also reveals the shaping power of gender on the experience of individuals in the school.

Experiences of Schooling: The Shaping Power of Gender

Gender contours how one experiences the world and particularly how one experiences the school.

Often, gender links in with other identity-markers such as race, language, geography, religion, etc., to configure how one accesses schooling, how one is seen in schools, and the pathways one takes through schools.

The special issue of *Gender and Education* (V.26, I. 5) is replete with articles on the ways that gender is meaningful particularly as it intersects with a rural context, within the site of the school. Multiple articles in this issue focus on the myriad ways that gender looks different – is practiced in a different way – in rural locations. This is true whether students are in countries in the West or in the Global South. Gender matters for getting to school, for access to curriculum, and for identity-making. Gender matters within the particularities of geography and location. The articles in this issue argue that it is this nexus – of location, culture, and gender – that is most meaningful for exploring practices toward equity and empowerment in education.

There are many other scholars who also highlight the importance of gender and a critical gender lens at the site of the school. Birkett and Espelage (2015) note that heteronormative discourses of masculinity lead to an increase in homophobic bullying in schools. When students identify with traditional notions of masculinity, they are more likely to call names and bully students; these students will bully others by using homophobic slurs.

Traditional notions of masculinity, and the ways these notions influence gender, can also be seen in the physical education classroom. Cameron et al. (2013) use a critical gender lens to examine biopedagogies; that is, they use gender as a way to explore how schools teach about bodies. These authors provide a Canadian-based look at the ways that discourses on what counts as healthy bodies translate into curriculum for both physical education and health classes. Traditional discourses of femininity and masculinity normalize certain body types, sexualities, and practices, and this has gendered implications. In many ways, these discourses reinforce idealized and heteronormative versions of embodiment and indoctrinate students toward this end.

Gender frames the experiences of the school. Traditional notions of gender articulate what counts as masculine, feminine, and normal. Gender contours the pathways one takes, whether they are pathways to STEM fields or other pathways. Gender formats access points: access to schools, access to safe spaces, access to careers, access to help, and access to guidance toward empowerment. A critical gender lens not only allows the excavation of the ways that gender shapes experience of the school in general, it also opens explorations into the professions of the school – of teaching and administration. Gender shapes what it means to be a teacher or a principal.

Schooling Spaces: Teachers and Principals

Multiple scholars have done recent work on the ways that gender configures practices of teaching and school leadership. Gender influences how teachers and principals behave toward each other and to students. Gender also becomes meaningful as a point of intelligibility. That is to say, gender issues and inequities are more easily seen when one pays attention to gender.

This truth can be seen in the work of O'Malley and Capper (2014) who argue that there is a lack of focus on LGBTQ issues and identities on the part of most principals. In O'Malley and Capper's study, principals were more aware of and more prepared to intervene in homophobia in the school when they went through a preparation program or professional development that focused on gender awareness and critical gender studies. O'Malley and Capper (2014) argue that there needs to be a greater focus on preparing principals to understand LGBTQ issues, identities, and policy complications and interventions. The focus on gender is part of advancing causes of social justice and creating a more equitable schooling environment.

Gender also makes a difference in leadership styles, according to Kochan et al. (2014). Principals have different leadership styles and ways of understanding their roles based on gender.

According to Kochan et al., women are more globally integrated with the community. They also have more of a macro-focus when it comes to problems within the school. Women tend to search for ways to bring voices together in order to solve problems. Men have more of a micro-focus when it comes to problems in the school. Men are more focused on discrete tasks and the completion of those tasks. Kochan et al. argue that male and female principals have different ways of interacting with staff, faculty, parents, and students. Gender differences contour how a school is run and the goals of each school.

Gender influences not only principals but also teachers. Gender differences can be seen even in teacher preparation programs. For example, Monaghan (2014) conducted a study on the perceptions of preservice teachers about the importance of gender. Monaghan found that while many preservice teachers believed that gender didn't matter anymore in the workplace, they simultaneously believed that their gender influenced their teaching style and student responses to their teaching style. These same preservice teachers believed that gender influenced interactions with parents and administrators. Many of these teachers have come of age in postfeminist times – and this experience colors their responses. These teachers articulated the postfeminist discourse that discounted gender as meaningful, even as they also articulated ways that gender made a difference in their own lives within the teaching profession.

The beliefs of these preservice teachers – that gender makes a difference in how you run a classroom and respond to students and parents and also that gender makes a difference for how others respond to you – are validated by the work of Sak et al. (2015). Sak et al. argue that there are gender differences in how teachers – and even preservice teachers – deal with feelings of confidence while interacting with others as a professional. Sak et al. were studying whether or not there were differences between males' and females' behavior management plans. While the researchers found that the plans had no significant differences based on gender, there were significant differences in the confidence to carry out

those plans. Particularly when it comes to dealing with parents, it makes a difference if you are male or female.

Conclusion

In the time of Aung San Suu Kyi, Ellen Johnson Sirleaf, Angela Merkel, and Hillary Clinton, it is easy to see why postfeminist discourses have so much commonsense appeal. Postfeminism also easily links in with neoliberal discourses that trumpet personal choice as the marker of all difference and access to resources. These discourses, together, aim to re-center traditional heteronormative modes of being and understanding the world. This comes at the expense of equity for all. Postfeminism invokes a sort of gender blindness. This discourse argues that we have already reached equality, and so difference no longer matters and should not be seen or noticed. The above examples of scholarship clearly push against postfeminism and show that gender has an incredible power to shape human experience. Gender still matters, and a critical gender lens allows deeper exploration into the ways that gender contours experience and equity.

Introduction: Critical Pedagogy and Visual Art Discourse

Critical pedagogy has a rich history in the fields of education and curriculum studies. Paulo Freire's seminal text, *Pedagogy of the Oppressed* (1968), is grounded in a Marxist class analysis. It posits education's purpose as mobilizing students to question their social conditions and to assert agency or the capacity to self-manage individually and collectively. Freire's concept of *praxis*, or the combination of critical reflection and action in service of a democratic and emancipatory project, reflects his conviction that education is inseparable from ethical and political concerns. His work set the stage for subsequent, more explicit explorations of race, sexuality, and gender. Drawing on Freire's work and the progressive education movement championed by John Dewey – in which he asserted the centrality of schools in producing a democratic citizenry – North America in the 1980s saw a development in critical pedagogy. This development manifested in the reconceptualist movement among others that incorporated critical pedagogy into curriculum

studies. This integration increased the demand for critical education, a shift that contested the sociopolitical turn to privatization, market-based logics, and austerity measures under Ronald Reagan (USA) and Margaret Thatcher (UK). The reconceptualists and what Henry Giroux identified as the “new sociology of education” (Giroux 1981) consolidated a connection between learning, politics, and the social condition. With its view of teaching as a moral, political, and intellectual practice, critical pedagogy unsettles common sense and highlights the struggle over agency.

Critical pedagogy shares with cultural studies and critical theory its analysis of power dynamics and its resulting social conditions. Beyond merely serving as a technical practice of transmitting knowledge or mastering skills, critical pedagogy transforms knowledge in the context of an ongoing struggle for social justice.

Similarly, art and politics have a long, entwined history. For centuries, visual art has functioned as aesthetic, formal, and sociopolitical critique, challenging dominant structures and conventions. The cyclical nature of the avant-garde, working at the periphery of prevailing discourses and eventually transforming them, illustrates how art at its most political can be defined as intervention. However, art discourses still largely fail to engage pedagogy as a central concern. This critical absence in the study of art in contemporary contexts, particularly as it relates to politics, agency, and social justice, must be addressed because art functions by mimicking or rupturing the dominant regimes of meaning making, power, and the production of subjectivities. The challenge artists and educators face today extends beyond fostering a critical engagement with the structural and ideological forces that shape social conditions; they must also cultivate a space in which critique is tied to action and the possibility of agency in altering those conditions.

The Neoliberal Conjuncture

Contemporary art discourse fails to recognize that pedagogy is central to art as a sociopolitical

process and how it can work to mediate and resist the neoliberal conjuncture. Neoliberalism manifests not only as an economic project but as a political one that normalizes modes of agency, desires, and institutional forms of power that mimic the privatized values and relations of a market-driven society. As Wendy Brown explains, neoliberal “rationality, while foregrounding the market, is not only or even primarily focused on the economy; rather it involves *extending and disseminating market values to all institutions and social action*, even as the market itself remains a distinctive player” (2003, par. 7). A critical investigation of the pedagogical dimension of art begins by looking at socioeconomic and political conditions and how they impact creative production culturally and structurally. An assessment of cultural production scrutinizes what is visible and communicable in the precarious social formations that have arisen since the 1980s under neoliberal structures and institutions. Political and economic formations legitimize creative labor within the parameters of individualism, the accumulation of capital, an economy of affect, and a retreat from an understanding of the common good. Under such circumstances, creative labor is funneled toward private wealth and commercial spheres that threaten those public spaces that promote critical thought.

Art is thereby in its own crisis, because it is depoliticized by marketization and profit-based goals. Simultaneously, digital platforms shift access to media in unprecedented ways, resulting in a massive swell in amateur participation (particularly in photography-based media). While technophilic and technophobic attitudes ascribe positive or negative value to this expansion, the implications are more nuanced: contemporaneity presents a new set of conditions that can either mimic or rupture the underlying sociopolitical inequalities that already exist. By exploring the relationship between critical pedagogy and art, it becomes possible to understand what such shifts imply for economic, technological, and social conditions. Although critical pedagogy is not foreign to academic and activist circles in its application to teaching institutions, it also must be

considered as a public issue, one that functions through cultural processes.

Art as Public Pedagogy

Culture and its production are characterized by "...a dialectical interplay between the class-specific behavior and circumstances of a particular social group and the powerful ideological and structural determinants in the wider society" (Giroux 2001, p. 101). Thus, we must approach visual culture and art by looking carefully at how they are used in constructing subjectivities. By recognizing visual culture as didactic, traditional education expands to include visual practices as part of its repertoire in examining emancipatory political dimensions.

In contemporary Western society, dominance and repression are largely leveraged through the manufacture of consent rather than through violent coercion. The struggle for consent plays out across culture, through the texts, images, and materials consumed and in the practices that construct identities. The so-called culture wars of the 1990s, or the battles waged between conservative and progressive values in education, climate change, reproductive rights, immigration, etc., were conflicts that relied on ideological consent and self-identification. As such, they permeated all aspects of cultural consumption and practice, not only the political realm. This didactically influential role of culture is not new. However, positioning art as central to political education extends beyond critique and becomes participatory when the public engages to effect social change. "Upon artists and cultural workers rests the important job of encouraging and facilitating forms of citizen-based cultural production. This task will necessarily entail the dismantling of old forms of art, arts institutions, and art patronage. For this reason we must contest at every opportunity pedagogies that deny the very real ways that we all both consume and *produce* culture" (Trend 1992, p. 5). Artistic production as a cultural process that depends on context is educative, and so, following the

premises of critical pedagogy, inextricable from questions of ethics and politics.

Every cultural decision is "an educational enterprise" (Williams 1967, p. 15). Raymond Williams's insight is central to understanding that culture comprises the most important educational body, influencing how people learn to negotiate their world and make sense of information to construct meaning. Williams calls this enterprise "permanent education," referring to the educative power "of our whole social and cultural experience. [Permanent education] is therefore concerned, not only with continuing education, of a formal or informal kind, but with what the whole environment, its institutions and relationships actively and profoundly teaches" (1967, p. 15). Cultural communication and consumption are pedagogical; teaching is "financed and distributed in a much larger way than is formal education" (1967, p. 15). Sites of extra-institutional education are where power is negotiated and contested, which Giroux refers to as "public pedagogy" (2011, p. 7). The educative force of culture challenges the assumption that traditional schools are the only locations where education takes place.

Both Williams and Giroux consider the ways in which the pedagogical dimension of cultural practices integrate with social and political forces, how they function as components of sociopolitical hegemony, and how consent is solicited and subjectivities formed. Williams warns that we are seeing "an integration of this teaching with the priorities and interests of a capitalist society... which necessarily retains as its central principle... the idea of a few governing, communicating with and teaching the many" (Williams 1967, p. 15). This integration expands and complicates the field of culture (thought to be inert in traditional Marxist models) and illustrates how cultural practices, institutions, and individuals influence one another. Public pedagogy – and education generally – is never neutral as it is socially located and produced from within systems of power and ethics. Therefore, it must also be understood as political, shaping practices, desires, identities, and struggles.

“Socially engaged” or “resistant” art is generally framed as art as symptomatic of larger cultural concerns, rather than as a central component in the production of our subjectivities and frameworks. Art making functions in a number of mutually reinforcing ways to inform social participation as a pedagogical and political practice. For example, highlighting the pedagogical and political in the production and staging of visual art raises questions as to why some representations have more power than others, how some modes of artistic practice are legitimized and others not, and how some sites of cultural display are valued and others not. By establishing the pedagogical and directive power of visual culture, we can begin to articulate how art is a socially pedagogical process. Art is central to public critique and can illuminate inequalities and oppressive political, social, and economic issues that critical pedagogy is poised to address. Art, however, is not a simply a vehicle for critique; rather, it may be that the current crisis necessitates creative approaches.

Art as Intervention

Jacques Rancière’s *Distribution of the Sensible* helps us understand how engagement with visual art is political. He examines what is included or excluded and heard or unheard, how the visible or invisible is formed through common modes of perception or the sensible, and how they are hierarchically prioritized. What we perceive informs how we structure political relationships, and they change as our perceptions change. How we perceive, order, and use images, for example, changes what we privilege or allow to emerge from the unseen. Aesthetic intervention becomes a political act because it reorders these hierarchies. Rancière’s caution, however, is to abandon any attempt to outline a causal relationship between aesthetics and politics: “We no longer think of art as one independent sphere and politics as another, necessitating a privileged mediation between the two – a ‘critical awakening’ or ‘raised consciousness.’ Instead, an artistic intervention can be political by modifying the visible, the ways of perceiving it and

expressing it, of experiencing it as tolerable or intolerable. . . . Now we must examine the very terrain of the sensible on which artistic gestures shake up our modes of perception and on which political gestures redefine our capacities for action” (Rancière 2007, p. 260). Art as political intervention must be understood as such because it is a cultural practice, determined by social location, history, and participants.

Such rupture provides a space in which alternative social and political configurations become possible. Expanding upon critique, which is only the first half of the equation, art as intervention has the ability to extend the parameters of social organization within which a literate and engaged citizenry can evolve. For example, New York-based artist and activist Caroline Woolard has not only dedicated scholarship to the project of a more equitable socioeconomic structure of exchange but positions artists as central to that project. Founder of Trade School and a creative community barter network OurGoods, Woolard reimagines what kind of exchange might function to rehabilitate public and social networks within an age of privatized services, the commodification of public goods, and ever-increasing socioeconomic precarity. Both OurGoods and Trade School bring together artists and community members to participate in alternative economies that champion civic exchange and mutual responsibility rendered from an ethic of social care. They resist neoliberal configurations that individualize social ills and prioritize market profits. Such artistic interventions can eventually shape the fabric of public values: in 2012, Argentina instated a writers’ pension program, providing support to authors and, more significantly, asserting the importance of creative labor to the civic, political, psychic, and ethical well-being of the country. While other countries champion austerity measures and the evisceration of public infrastructure that includes funding for the arts, programs such as this resist profit-based logics that prioritize quantifiable financial returns, insisting instead on the role of artists as public intellectuals. The writers’ pension is a system for acknowledging the role that artists as intellectuals play in shaping a society and forming its culture,

a way to recognize the public and civic contribution their work makes.

Artists as Public Intellectuals

The public intellectual's work is to provide new skills, expand the ethical imagination, broaden the possibilities of civic life, and engage people in ways that confront them with difficult questions, inviting them to consider new perspectives. Artists' critical interpretations can help us with reflexive analysis – to view the social condition and broaden perspectives. They help us to re-envision what is and what is possible by being “the sensitive point of [their] community,” (Achebe 1988, p. 30). Carol Becker asserts that “[I]n denying artists their rightful place in the public consciousness, we are in fact negating the most creative part of ourselves individually and collectively and in so doing are also damning our future to one without experimentation and the vision needed to give it meaning” (Becker 2001, p. 20). This experimentation and vision are precisely what a democratic citizenry demands: it supports the commitment and the responsibility to question and ultimately to hope.

A central role of the artist is to make the connection between private troubles and larger social concerns, resisting the neoliberal ethic of placing the responsibility for social ills squarely on the shoulders of the individual. It is this act of connecting private and public – this movement between individual perceptions and desires and the world of ideas, events, and everyday life – that begins to reconstitute the public sphere through visual work.

The struggle to do this requires an awareness of artists as public intellectuals who contribute critiques and alternative approaches to political and social issues. Their work factors into public pedagogy in a way that stresses the educative nature of representations, power, and politics. Such work has the potential to politicize public discourses. The sensibilities of artists are “distinctive and important to the well-being of society” (Becker 2001, p. 13), so their artistic interventions and

pedagogical work become a question of social and public good, as recognized, for example, through the Argentinean writers' pension. Critical art that addresses political and ethical concerns has the potential to function pedagogically in service of critical and civic literacy and not merely a source of news or entertainment.

Cuban artist Carlos Martiel engages questions of race as embodied and inscribed by using his own body as the site of art. His performances locate sites of racial violence and struggle on his own body, connecting this intimacy to its structural and ideological basis. His performances are sensitive to the sociopolitical and geopolitical contexts in which they take place. In his work *Ruins* (2015), in Dallas, Texas, he lies naked in a fetal position, while two white men cover him with stones until his body is rendered invisible. In *Ciudad* (2015), performed in Los Angeles, he lies under stones and sediment gathered from different L.A. neighborhoods where people have been killed by police (Fig. 1). At a time in the USA where racialized violence is legitimized by a neoliberal police State and politic of disposability in which people of color are targeted, work such as Martiel's reconfigures the channels through which the public is confronted by and is compelled to confront difficult knowledge. As an artist, he assumes a particular responsibility to take seriously the ethical implications of his own production. Though critical work need not be overtly political, it functions within a didactic relationship that is inherently political (Fig. 1).

This didactic potential of visual art is central to critical pedagogy, which in no way suggests that teachers renounce their authority. In fact, the disavowal of power only serves to obscure it, not change, challenge, or shift it. While critical pedagogy is dialogical, it is also directive, meaning that the exchange between students and teachers (or the public and public intellectuals) is one of guidance: soliciting responses and making the material meaningful by being attentive to the lived realities of the students.

Authority is identified and examined rather than renounced: authority presents itself as the

Critical Pedagogy and Art, Fig. 1 Carlos Martiel. *Ciudad*, 2015. Steve Turner, Los Angeles, USA. © Carlos Martiel, courtesy Steve Turner

possibility to intervene, to teach skills, and to encourage development of agency. The authority of artists is one of intervention as well – to publicly present alternative perspectives that encourage critical engagement and agency. Authority also implies responsibility: the commitment to speak as a public intellectual is to be responsible for one's opinions and actions as an educator. That responsibility is political because it necessitates naming and intervening in power structures that shape the social condition.

The critique of authority in art discourse raises questions of subjectivity, of audience reception, and of participation. While it is important to recognize what the audience brings to a work of art, the danger of an orthodox attachment to reception – the insistence that meaning and significance are open and dependent solely on viewer perspective and taste – is that it degenerates into relativism. Suggesting that people can interpret things any possible way ignores the structuring of options that are available to them; viewer response is not infinite nor is it arbitrary – it depends on the structural conditions and ideological forces that determine those perspectives. A relativist view is abstracted from power; it

ignores why some meanings are more dominant than others. The most potent forms of domination are not only structural and economic but also ideological and pedagogical and rely on elements of belief, affect, modes of identification, and the symbolic dimensions of struggle. Public intellectuals are responsible for contesting this particular form of domination, and artists are particularly poised to address the myriad ways that ideology shapes our social condition.

Conclusion: Critical Visual Literacy

Art as a pedagogical practice establishes connections between discourses previously held separate from traditional pedagogical concerns such as race, gender, and sexuality. Art-making is an intersectional endeavor, with artists connecting and translating between not just public and private issues but ones that span diverse yet entrenchedly connected discourses and subjectivities. Visual culture – and by extension the use, mediation, distribution, and social effects of art – forms an important component of the pedagogical dimension. How we understand our visual world as well

as our role within it must be informed by critical visual literacy. Literacy in this sense is not just about competency but also about interpretation as intervention in the world. It comprehends the pedagogical practice of engagement in a culture of challenging common sense assumptions that are reinforced by apparatuses of power and representation. This means the struggle over agency, not just over images or objects. If art is understood as intervention, then it addresses the educative nature of politics.

The pedagogical work that art does is present in what it communicates through its content and in how it communicates narratives or concerns about the nature of art itself. Visual art inserts itself in the public as a mode of production that is directive; it seeks to mobilize and alter forms of perception and one's relationship to the object, the self, and to others. At best, it connects the issue of visual literacy not only to the possibility of interpretation as an intervention in the world but also to matters of political agency, democracy, and public life.

Critical Pedagogy and Digital Technology: Postmodernist and Marxist Perspectives

Katarina Vuković Peović¹ and Petar Jandrić²

¹University of Rijeka, Rijeka, Croatia

²Department of Informatics and Computing, University of Applied Sciences, Zagreb, Croatia

Introduction

Human learning cannot be thought of without technologies. Yet, while the movement of critical pedagogy has always been interested in educational usage of mass media, in the second part of the twentieth century “there has arguably been less interest in the fourth major platform of the Freirean program – economic development through technological modernization processes” (Kahn and Kellner 2007: 434). At the brink of the new millennium, human society has rapidly become saturated with information and communication technologies. In order to make sense of education in the age of emerging digital cultures, mainstream critical pedagogy has employed two major philosophical traditions: postmodernism and Marxism. Marxism is a social theory that emerges from the late nineteenth century and the works of Karl Marx. (There is also a term “Marxian theory” which stresses the fact that emerged studies follow the work of Karl Marx but not necessarily follow Marx’s teachings in full.) Postmodernism is a late twentieth-century philosophical tradition and broader social movement that criticizes universalism and emphasizes social constructivist understanding of reality. Postmodernism and Marxism are centered around the importance of power relationships; they believe in fundamental importance of progress in scientific and technological achievements; and they share a common goal of overcoming social and epistemic dualisms.

Critical pedagogy is firmly based in the Marxist tradition of the Frankfurt School of Social Science. During 1980s and 1990s, however, postmodernism has attracted significant attention from

critical theorists such as Peter McLaren, Henry Giroux, Michael Peters, Douglas Kellner, and others. With time, their theories developed in various directions. For instance, Peter McLaren leads the way in abandoning postmodern approaches by returning to “the Marxist-humanist trajectory” and the original works of Marx, while Michael Peters’s work is usually associated to postmodernism and poststructuralism (Lăzăroiu 2014: 3916). While Marxism and postmodernism can in many ways be seen as complementary, differences between the two traditions are particularly prominent in relation to the nature of modernity and the relationships between digital technologies and human learning. On that basis, this entry locates the main issues pertaining to the relationships between critical pedagogy and digital technologies in the traditions of Marxism and postmodernism.

Postmodernism, Technology, and Critical Pedagogy

Postmodern societies are typically defined in relation to new ways of production that emerge from technological inventions. Sometimes, “postmodernism” refers to broader cultural and political contexts, while “postindustrial society” (Bell 1973/1999; Touraine 1971) defines more specific political and economic contexts of production in late capitalism. The term “postindustrial” stresses the three phases and the three ways of production. For many centuries, the humankind lived in the preindustrial society dominated by manufacturing. In late nineteenth century, the preindustrial society was superseded by industrial societies based on steam engine. Finally, after World War II, postindustrial societies emerged and brought about new ways of production interrelated with progress in communication technologies and computerization. By and large, postmodernists list information technology as a crucial element of the historical shift towards the postindustrial, network society.

Yet, this period is also defined by other important features. Bell outlines three crucial components of the period: a shift from manufacturing to

services, the centrality of the new science-based industries with the rise of new technical elites, and the advent of a new principle of stratification (Bell 1973/1999). In this new technologically oriented society, claims Bell, technology and science helped in installing instrumental rationality not only as way of production but also as a political form and a ruling model. Such interpretation of history, known as the “endism,” was taken to its extreme by Francis Fukuyama. As opposed to Bell and Fukuyama, Touraine agrees on the importance of the new spheres of life where knowledge, consummation, and culture play a major role in the society. Yet, he sees no agreement between opposed forces in the society and describes new forms of dominance carried by technocratic elites. Clash between workers and capitalists have only become institutionalized and de-politicized, while alienated work remains the foundation of social stability (Touraine 1971). Jameson opposes the very notion of disappearing industrial production and claims that theories of postindustrial society have the ideological mission – to denounce the primacy of industrial production and the omnipresence of class struggle (Jameson 1991, p. 2). He suggests that the postindustrial society is not a new, but a purer stage of capitalism and that the disappearing of traditional social classes is an illusion. This conviction has an immediate effects on political praxis, while reassuring emergence of postpolitical practices (1991, p. 53).

On the fringes of the two mainstream ideological camps, there is a prominent group of theorists and practitioners who claim that digital technology opens new possibilities for implementation of revolutionary ideas. Brought by nonhierarchical distribution of information, the scope of distribution of information is greater than ever. It has become technically possible to open archives, libraries, and repositories of books, audio, and video materials. Such development is related to ubiquitous digitalization of analog information and its decentralized distribution, which reflects to all social strata – including human learning and institutionalized education. Yet, critics point that digital technologies are far from neutral and, moreover, that digital technologies are

dialectically intertwined with the so-called Californian ideology – which essentially reflects, and perpetuates, core values of capitalism (Barbrook 1999).

In regard to the above discussions, critical pedagogy movement is far from coherent. However, based on the rich legacy of its most prominent members such as Paulo Freire and Ivan Illich, critical pedagogy movement approaches digital technologies and the postindustrial society both with positive curiosity and caution. In late twentieth century, an important aspect of accounting for this complexity was through the postmodernist route. At a time, McLaren claims “that the current revolution in social theory demands a new set of critical paradigms within educational theory that can account for the heterogeneity of pedagogical and curricular discourses and complexity of meaning production in postmodern cultures” (1995, p. 188). Similarly, Giroux and Aaronowitz argue that “postmodernism provides educators with a more complex and insightful view of the relationships of culture, power, and knowledge” (1991, p. 133). While recent works by McLaren and other critical educators have significantly developed from hard postmodernism characteristic for late twentieth century, postmodern approaches have significantly informed contemporary critical pedagogy and its relationships to digital technology.

Marxism, Technology, and Critical Pedagogy

Marx’s standpoint on technology is elaborated in his well-known concept of base and superstructure. Marx stresses the central role of technology in the progress of history and describes economic base as the material foundation of the society that includes forces of production and relations in production. Forces of production are technologies, machines, and raw materials; relations in production are class relations between the ruling class and the powerless class (i.e., between slave-owner and slave, feudal lord and peasant, factory owner, and wage-worker). Superstructure, which includes legal, political, religious, artistic, and

philosophic ideological forms of social consciousness, is determined by the base (Marx). This topological concept of the society is linked to historical materialism, which postulates technology as one of the most important elements in society. In the Marxian perspective, material base of the society must be accounted as the starting point of social analyses.

For Marx, the main problem with the capitalist society remains in the base, since the machinery and large-scale industry are in the hands of the powerful elite. “In no way does the machine appear as the individual worker’s means of labour” (Marx 1993, p. 692). Forces of production are therefore closely linked to class struggle. “It would be possible,” he observes, “to write a whole history of the inventions made since 1830 for the sole purpose of providing capital with weapons against working class revolt” (Marx 1976, p. 563). This is simultaneously a limitation, and a progressive force. “At a certain stage of their development, the material forces of production in society come in conflict with the existing relations of production” (Marx 1904, p. 12) – and this conflict causes social revolutions. As a corollary, the social base is the powerful force of social change.

Marx notices an important contradiction within the capitalist mode of production. As capital continuously aims at maximization of productivity, it invests in general intellect, which is responsible for progress in scientific knowledge. Capital allows for an increase in the free time necessary for the growth of the general intellect. But capital allows such growth only in order to maximize profit. Capital is the moving contradiction, since it presses to “reduce labour time for the whole society to a diminishing minimum, and thus to free everyone’s time for their own development” (Marx 1993, p. 708). In the crucial moment, capital is forced to create disposable time: nonlabor time, free time for all. On the one hand, the tendency is always to create disposable time; on the other hand, this time needs to be converted into surplus labor. Capital depends on appropriation of surplus labor. Yet, it must reduce labor time for personal development, which creates opportunities for new inventions. The more this contradiction develops, the more it becomes evident that

the growth of the forces of production can no longer be bound up with the appropriation of alien labor. Instead, workers must themselves appropriate their own surplus labor (Marx 1993, p. 708).

Critical pedagogy has always been based on class analysis. In his later works, McLaren analyses the postmodern turn characteristic for late twentieth-century critical pedagogy, takes a firm stand against “the ironic distantiation and self-indulgent detachment of the vulgar divas of the academy who clearly chose identity politics over class politics (and in so doing became complicitous in the very relations of inequality they officially rejected),” and seeks solution in “a close reading of Marx and Marxist theorists” (McLaren and Jandrić 2014, pp. 806–807). During the first decades of the twenty-first century, many critical educators have embraced similar views. Based on contemporary Marxian thinkers such as Antonio Negri, Michael Hardt, Raniero Panzieri, Mario Tronti, Sergio Bologna, Miorosia Dalla Costa, and Francois Beradi, and classical Marxist critiques of Mas’ud Zavarzadeh, Teresa Ebert, the Marxist humanism of Peter Hudis, Kevin Anderson, and Raya Dunayevskaya, Marxism has entered the works of British educators such as Paula Allman, Mike Cole, Dave Hill, and Glenn Rikowski and then, once again, spread throughout the critical pedagogy movement (McLaren and Jandrić 2014, p. 807). In regard to technology, Marxist thought in contemporary critical pedagogy is still fairly underdeveloped. However, as critical pedagogy has started to blend with more technology-oriented fields such as media studies, Marxist views are slowly but surely shaping the relationships between critical pedagogy and digital technology.

Digital Technologies, Postmodernism, and Marxism

The self-contradictions of capitalism that inevitably bring social and economic revolutions result in Marx’s famous anticipation of a transition from capitalism to communism. While this unfulfilled prophecy has always been under heavy attack,

many believe that Marx merely mispredicted the duration of the transitional historical period – and that digital technologies are an important step towards communism (Barbrook 1999). This creates new utopian visions of digital technologies, which are seen as a melting pot of postmodernism, technologies, and Marxism. Postmodern era is understood as a period of historical transition, where forces of production come into a conflict with relations in production – and this conflict may lead to social revolution. As the only media that allows direct connection of two users without hierarchical mediator, the Internet has radically decentralized production and distribution of information. Based on decentralized media structure, new digital tools have created an initial gap in the capitalist production, especially within extrapolating the surplus value.

Distributive horizontal technologies are extensively discussed within the Marxian notion of general intellect. In order to appropriate Marx’s elaboration of general intellect within the contemporary context, and the concept of public good in particular, Virno, Hardt, Negri, and others have introduced the concept of the “multitude.” Hardt and Negri describe creative forces of the multitude as capable of autonomously constructing “an alternative political organization of global flows” (Hardt and Negri 2000, p. xv). Nick Dyer-Witheford, Johan Söderberg, Christian Fuchs, and others start from similar presumptions and relate digital technologies with long-standing social struggles.

Barbrook directly relates postmodern technologies, and peer-to-peer networks in particular, to the development of “cyber-communism” (Barbrook 1999). Drawing from Marx, he describes the era of *digerati* – the new innovative generation of technology-worshippers. Paradoxically, the advent of the Internet – caused by the Cold War – introduced a form of Stalinism on the West, as Californian ideologists were obsessed with the progress of technologies. The standard teaching of *digerati* – “the ruling of the few will free us all” – heavily resembles the Stalinist ideology and Soviet leadership. Yet, Barbrook also identifies counter-forces in the mechanisms similar to Marx’s general intellect.

He describes the initial conflict within digital technology as the opposition between various gift economies and “market competition at the cutting-edge of modernity” (Barbrook 1999).

The practice of gift economy, sometimes also called “the potlatch,” can be traced from Polynesian tribes. In these societies, instead of accumulating surpluses, individuals gain prestige by giving away their wealth at public celebrations. The main force working against the gift economy in digital media is in defining digital products outside of surplus value. However, that is exactly what happened within the academic community, where – in spite of increasing commercialization and commodification – scientists freely share their findings, as such practices happen to be the most efficient method of progress. Paradoxically, it is the very practice of academic open sharing that created digital technologies as we know them. Upon entering the marketplace, however, these practices have created the conflict within capitalist mode of production – and this conflict is one of the main defining features of the contemporary Internet.

This conflict can be illustrated using three examples. The first example is peer-to-peer networks. Radical democratization of distribution of information, presents on these platforms, initiates one of the greatest conflicts within capitalist mode of production. Development of bourgeois society is accompanied with the logic of industrial production and the logic of production of standardized, unified copies, protected by copyright. Peer-to-peer networks clearly endanger copyright and create the initial contradiction in the capitalist mode of production and extrapolation of surplus value within the postindustrial society. The second example of the digital technologies as novel forms of Marx’s general intellect is within the commons. In a broad sense, “commons” are all goods that (should) belong to everyone – however, capitalist mode of production tends to privatize all commons. Taking information as commons, therefore, another contradiction of late capitalism is that “information wants to be free but is everywhere in chains” (Wark 2004, p. 126). The third example is the free/libre/open source software. Usually distributed under so-called copyleft licenses, such

software promotes free usage and modification for as long as it is distributed under the same conditions.

The identified conflict is highly relevant for critical pedagogy. In order to capture its full complexity, postmodern understandings of digital technologies are dialectically intertwined with Marxist concepts. Radical democratization of distribution of information is directly linked to critical emancipation; understanding of information as a commons is prerequisite for equal opportunity; the free/libre/open source software is a convivial tool which removes the differences between producers and consumers of technology (McLaren and Jandrić 2014, pp. 814, 815) – and these examples are just the tip of the iceberg. The self-contradictions of capitalism continue to transform various social practices such as the traditional industrial notion of copyright. However, at present, they still seem to avoid direct large-scale conflict with the capitalist mode of production.

Conclusion

Postmodernism and Marxism arrive in diverse forms and traditions that have continually informed each other in the context of contemporary critical pedagogy and its relationships to digital technology. Therefore, postmodernist and Marxist insights cannot be viewed separately from each other. In words of Michael Peters,

These labels ‘revolutionary Marxism’, ‘postmodernism’ and ‘poststructuralism’ should be not taken too literally in my view. The process of identification by association can be scary but like any stereotyping mechanism we can and should reject these broad descriptions as being definitive of philosophical identity and work instead with what scholars say — we should follow the arguments. (In Lăzăroiu 2014)

Certainly, there are many tensions between (various forms of) postmodernism and Marxism. Postmodernists may look down to Marxist belief into the inevitable arrival of communism; Marxists may struggle against postmodern primacy of identity politics over class politics. However, problems of contemporary capitalism require theoretical

engagement with alternative futures, while class politics cannot be thought of without identity politics – and vice versa. In the age of digital cultures, postmodernism and Marxism should be understood as inherent parts of critical pedagogy and its relations to digital technology – and the ones that might be instrumental in the never-ending process of its reinvention.

Introduction

Not all of the core ideas of critical pedagogy are brand new. Like any other new perspective, critical pedagogy is built on previous theories and ideas. For example, the idea of constructing knowledge *with* students was already present more than 100 years ago in John Dewey's idea of "experience" (1902) and more recently in constructivism (Vygotsky 1978). The idea of schools-as-change agents is not new either. In the early twentieth century, social reconstructionism was based precisely on the idea that schools can and should effect social change (Counts 1932). More recently, we can find the same idea in the civil rights movement and multicultural education. True, one may say that critical pedagogy is more overtly political than the progressive education movement, constructivism, or multicultural education. Yet it is undeniable that there are some similarities among these educational theories. Besides, there were individual teachers who were actually practicing critical pedagogy in their classrooms well before the term critical pedagogy was invented! Why then was this new name critical pedagogy coined? What were the historical contexts that gave birth to critical pedagogy? If many of its ideas are not new, where can we draw the boundaries for critical pedagogy? This entry explores the historical context for the origin of critical pedagogy. The origin is important to understand, because it has shaped what critical pedagogy is and has become – its identities, its foci, its agendas, its politics, and its projects.

The Foe: Mainstream Education Paradigm

One good way to understand what critical pedagogy is *for* is to figure out what it is *against*. It is apparent that critical pedagogy is against the mainstream education paradigm. By and large, critical pedagogy rejects two major premises of the mainstream education paradigm. The first premise is the idea of schools as the “great equalizer.” In the mainstream education paradigm, schools have largely been considered meritocratic institutions, which provide equal and fair opportunities to all students. Critical education theories point out that schools have never provided equal opportunities to all, and although educational opportunities have expanded over time, there are various mechanisms in schools which discriminate against some students who are considered to be the “others.” Furthermore, they argue, schools play the function of reproducing the existing inequalities and of legitimizing this reproduction. That said, there are different positions among critical pedagogues. Some critical pedagogues agree with the liberal’s position, which sees the outcome of inequalities in school as the exception (due to an imperfection of the school system). However, there are other critical pedagogues who see that schools are set up to re/produce unequal outcomes, and therefore, inequalities are not “unintended” outcomes. To put in another way, there is a more liberal version of critical pedagogy and a more radical version of critical pedagogy.

The second idea to which critical pedagogy objects is instrumental reasoning. One essential perspective in the mainstream education paradigm is seeing schooling as a means to an end, both for individuals (such as, for getting a better job) and for the society (such as, for economic development or nation building). Critical pedagogy criticizes this instrumental rationality and reification, which leads to dehumanization and oppression. Instead, the critical education paradigm tries to transform schools for humanization and for social change. While the mainstream perspective views schools basically as institutions to maintain the existing social system (via improvements and reforms), critical pedagogy views schools as

social institutions that should seek to change the society. This difference on the role of schools is ultimately due to how each paradigm views the society at large. If one views the society as equal and just, the role of schools would be to socialize its members in order to maintain and reproduce the society. But if one sees the society as unequal and unjust, then the role of schools would not be to reproduce the existing unstable social system, but to change it for the better. Because of its opposition to a technocratic framework of the mainstream paradigm (focusing on the how’s), critical education/pedagogy is fundamentally and inevitably a “political” paradigm which focuses on power and its relations to education.

The Counterpart: Neo-Marxist Education Theories

As Wallerstein (2004) points out, new perspectives are better understood if we think of them as “a protest against older perspectives” (p. 1). The counterpart for critical pedagogy is the earlier critical theories, especially neo-Marxist education theories. So, what is it about neo-Marxist education theories that critical pedagogy is protesting against? During the post-civil rights era, a renewed interest in critically examining the larger roles of schools in the capitalist society emerged. Contrary to the liberal belief that schools reduce inequalities, Bowles and Gintis (1976) maintain that education in a capitalist society (in the USA in this case) reproduces fundamental economic inequalities. Subsequent critical education theories have tried to elaborate Bowles and Gintis’ work, by venturing to explain how the reproduction process occurs through schools. They have employed the works of Gramsci, Althusser, and Stuart Hall and have introduced new concepts, such as cultural capital, hidden curriculum, and ideology/hegemony (Bourdieu and Passeron 1977; Apple 1979; Carnoy and Levin 1985). The main claim of these works is that the school, as a part of the culture/superstructure, plays a significant role in re/producing and legitimizing the hegemony of a capitalist society.

Neo-Marxist theories have been very successful in providing powerful critiques of schooling. However, what they have not been very successful at, and thus have been frequently criticized for, is presenting feasible alternatives of schools-for-social change. If education and politics are primarily determined by the economy as argued by Bowles and Gintis (1976), many educators lament that there would be little that could be done in schools to change society in any fundamental way (except, of course, an economic revolution of sorts). It is this lack of alternatives that prompted the emergence of critical pedagogy in the 1980s. Critical pedagogy attempts to correct the deterministic and pessimistic conclusions of neo-Marxist theories and to transform a “language of critique” into a “language of possibility” (Giroux 1997, p. 108).

The very identity of critical pedagogy was formulated as reactions to neo-Marxist theories. However, the reactions vary from critiques, to further elaborations, to rejections. In some respects, critical pedagogy has been about the elaboration and extension (thus, continuation) of earlier critical education theories, and in other ways, it has been about differentiating itself from neo-Marxist theories. As critical pedagogy emerged in order to counteract the structural and economic determinism of earlier critical educational theories, it is only logical that critical pedagogy has turned to *agency* (against structural determinism) and to *culture* (against economic determinism). These redirections have led critical pedagogy more toward microlevel politics (individuals, classrooms, and teachings), where educators supposedly have direct impact. This is not to say that critical pedagogy theorists have promoted only microcentered pedagogy and politics. However, as it stands today, much of the critical pedagogy literature and praxis tends to focus on classroom pedagogy and agency.

The Savior: Paulo Freire

From where, then, did critical pedagogy find the “language of possibility”? Critical pedagogues turned to various theories; however, many would

agree that it was from Paulo Freire that critical pedagogues ultimately found the language of hope. Why did critical pedagogy turn to Freire? The obvious reason is because he offered the elements of hope and possibility. Rather than viewing schools as a mechanism of social control and reproduction, Freire argued that education could be liberatory even within the most limiting circumstances. He saw education as the practice of developing a critical perception of reality among learners/participants, which could effectively lead to what he called “conscientization.” Freire appealed to critical pedagogy because he offered “not just a narrative but also a methodology of liberation” (Lissovoy 2008, p. 11), with steps to follow, which he called “a methodology of conscientização” (Freire 1997, p. 85).

While Freire offered a pedagogy of hope and transformation, there are some challenges and problems in adopting Freire in critical pedagogy. One challenge is that Freire’s key concepts – history, humanization, critical (dialectical) perception of reality, and the relationship between the object and the subject – cannot be correctly comprehended without background knowledge and understanding of Marxism. However, the Marxist basis in Freire’s thinking often eludes readers, and this is why, as Allman (1999) argues, Freire has been so often misunderstood and misapplied as just a teaching method. Unfortunately, this misunderstanding and misuse of Freire still can be seen in some critical pedagogy literature.

There are other issues with how the utilization of Freire directed critical pedagogy into certain directions. Since Freire’s main focus was on transforming the consciousness of individuals, critical pedagogy tends to focus on individualized projects. Also, his emphasis on cultural action and cultural revolution influenced and directed critical pedagogy towards cultural politics. That said, it should be noted that the dominance of cultural politics in critical pedagogy is not exclusively due to the influence of Freire (more on this below). Rather, this “cultural turn” was a general trend which influenced both Left politics and academics since the 1970s. In addition, there is an issue regarding the relationship between pedagogical projects and political projects. Freire sees pedagogical projects

as an essential part of political projects, yet he also makes clear that pedagogical projects (critical perception of reality) do not necessarily lead to political transformation. However, because Freire's works largely focus on pedagogical projects, it is easy to neglect other conditions for liberation in critical pedagogy, which in turn can thwart the discussion of how pedagogical projects could actually lead to political projects.

The Contour: Postmodernism

At the time when critical pedagogy theorists were trying to find an alternative education (language of possibility) apart from and beyond neo-Marxist education theories, a sea of change was surging. Since the late 1970s, critical theories have been moving away from Marxism (or a version of Marxism, called by various names such as, structural Marxism, material Marxism, orthodox Marxism, or vulgar Marxism), and a new kind of critical theories began to get more circulation. This was the rise of posttheories: poststructuralism, postmodernism, and postcolonialism. Critical pedagogy was heavily influenced and shaped by this wave of change.

One key influence of postmodernism is to position culture at the center of critical pedagogy. For instance, McLaren (1995) defines critical pedagogy "as a form of cultural politics" (p. 42). While the approach to culture in critical pedagogy is diverse, from as a medium of discipline and social control to as a site of resistance and possibility, the current use of culture in critical pedagogy sways more towards the resistance/contradiction/rupture approach (Cho 2013). This is partly due to their attempt to overcome the seemingly pessimistic position of earlier Marxist theories of education. In a way, culture has rescued the critical theories of education from a no-solution alternative. However, the problem is that these studies tend to glorify the power of culture in transforming society. Overresistance and overcontradiction are not the same as the crumbling of social system.

The other contribution of postmodernism is a new understanding of subject formation. Contrary to

Marxist theories, poststructuralists see subject formation as much more complex, indeterminate, and loose. According to poststructuralism, subject formation involves more than and beyond ideology and consciousness (ideas and beliefs), which includes feelings and desires. Therefore, subjects are not only more complex, but also more fragmented, floating, and indeterminate. Poststructuralist's keen attention to subject formation – infusing concepts from psychoanalysis – provided a sensibility to other forces (more than class) that shape our subjects. This was a much welcomed idea particularly for feminists and antiracism scholars.

As critical pedagogy is deeply couched in postmodernism, there exists an irony. At its core, postmodernism is a discourse of incredulity or impossibility (Lyotard 1984). Postmodernism rejects the Enlightenment projects of modernism, and at the same time it is a skeptic and critique of the revolutionary projects of Marxism (they call Marxism a "high" modernism). So, it is an interesting twist that the quest of critical pedagogy (language of possibility) ended up with and at postmodernism (discourse of suspicion). There are two positions on how to combine these two seemingly contradictory discourses. On one side, the so-called critical/resistant postmodernists incorporate postmodernism without giving up "possibility" as its ultimate objective. On the other side, other poststructuralists and postmodernists in critical pedagogy object to the very idea of possibility as "totalizing" and "moralizing" (Sidorkin 1997; Gur-Ze'ev 1998; Biesta 1998).

The Challengers: Feminism and Postcolonialism

Almost immediately after critical pedagogy emerged and its ideas were circulated, feminists (that is, white feminists) began to challenge critical pedagogy as being based on liberalism/modernism, which is a male-oriented theoretical construct (Ellsworth 1989; Luke 1992). Based on this critique, they have presented "feminist poststructuralist theories" as a better direction for critical pedagogy. The emphasis on multiplicity and the subject formation in the poststructuralism/

postmodernism is a right fit for feminists who have been looking to carve out space for their assertion. Thus, Michel Foucault has become their favorite, competing against or dethroning the old symbol, Karl Marx. While feminists have been successful in pioneering the introduction of poststructuralism and postmodernism into critical pedagogy, they have not been as successful in presenting alternatives. It is not clear where critical pedagogy would go in the end, if it rejects, as these feminists have promoted to do, basic conceptions that underlie critical theories, such as social justice, equality, and democracy. For instance, if we acknowledge that social justice is a modernist/liberal concept and thus to be abandoned, then what would and should be the guiding concepts for critical pedagogy? Or ought we not to search for guiding principles?

Along with feminists, there is another challenger of critical pedagogy, and they are antirace theorists. Many have already pointed out that critical education and critical pedagogy do not adequately address the issue of race (Hooks 1994; Leonardo 2002; Allen 2004). However, they argue that the class-based political foundations of critical pedagogy have remained intact, and thus the question of race has played a secondary role in the development of critical pedagogy. Similar to feminism's entry into critical pedagogy with poststructuralism, race has also entered critical pedagogy with postcolonial theories. To simplify to the core, poststructuralism is a study of the relationship between power and knowledge. Recent race studies took poststructuralism in their theoretical frames and inserted race and colonialism into the equation. Thus, postcolonialism is, in essence, a study of the relationship between *colonial* power and *colonial* knowledge (Loomba 1998). Because of its focus on knowledge, postcolonial studies gear heavily towards discourse, culture, and superstructure (as with postmodernism in general). We can see this in the fact that the three masters of postcoloniality (Said, Bhabha, and Spivak) are all literary theorists, which is by no means a coincidence. While postcolonial theories have introduced and guided critical studies to a much needed deeper understanding of race, the lop-sided focus of the culturalist approach has

been criticized for neglecting the structural and materialist understanding of race.

Countering the class-centered approach of Marxist theories, feminists and postcolonialists argue that there is no one center, but multiple marginalities, and the significance of any marginality is contextual, not predetermined. Acknowledgment of heterogeneity can be a sensible antidote against sexism, racism, and Eurocentrism. However, cultural/identity politics of postmodern feminism and postcolonialism tends to lead to fragmented and single issue-based praxis, and they generally takes the form of anti-State strategies (as has happened in the New Social Movements). And these politics, as some critics warn, may not be a proper position to fight against powerful global capitalism.

Concluding Remarks: The Boundary Issue

What was described above is historical origins of critical pedagogy as a *field of study*, not of critical pedagogy as an *idea*. As stated earlier, the idea of critical pedagogy existed long before the emergence of critical pedagogy as a field of study in the 1980s. This leads us to the questions of critical pedagogy's boundaries. How do we decide which are critical pedagogy and which are not? Who are critical pedagogues and who are not? Some people see critical pedagogy as mainly about teaching (pedagogy in the narrow sense) and thus focus on the microlevel. On the other hand, there are those who see critical pedagogy more on a macrolevel, focusing on the broader power relationships between schooling and society. To put it differently, the microposition gives its credence to critical *pedagogy*, while the macroposition emphasizes *critical* pedagogy.

Regardless of where one sees the boundaries of critical pedagogy to be, there have been some crucial changes in critical education, with the emergence of critical pedagogy. The search for alternatives/possibility and the influence of postmodernism have directed critical pedagogy into more on the microlevel (individuals, classrooms, and teaching). This is not to say that critical

pedagogues have only promoted microcentered pedagogy and politics. Many critical pedagogues are aware of the extant systematic problems and desire more fundamental changes to the system. However, critical educators are overwhelmed by the amount of work required for such systematic change. How do we change the system? Is it feasible to abolish capitalism? This all seems simply too much to even begin to imagine. Thus, critical pedagogy has ended up concentrating on schools and classrooms and emphasizing the “process” (how to do critical pedagogy). In its emphasis on the process, the process itself becomes the goal of critical pedagogy. In other words, a microlevel focus tends to lose track of the prize, which is social change; however, one defines it.

Critical pedagogy has thrown the necessary question to critically minded educators: What are our alternatives? Isn't it time for critical educators to present alternative/counter-hegemonic visions of education? Of course, this is not a new question. For a long time, critically minded educators have been working on this very question. Yet critical pedagogy has pushed us more forcefully to rethink and refocus our energy for “alternatives.” Due to the discourse field and theoretical trends at the time of its birth, critical pedagogy has ended up with a lop-sided focus. However, despite its flows, the question that critical pedagogy has thrown to us remains the right one: “What is our alternative education?”

Critical Perspectives on Postfeminist Discourses

Introduction

Postfeminist discourses emerging in the political economic sphere in the early twenty-first century frame gender equality as nonthreatening to the status quo. Such discourses appeal to the next generation of young people by making requirements for enhancing gender equality seem simple, practical, and typically noncombative. In the political domain, the United Nations He-For-She initiative (UN Women 2016) asks people to take basic individual actions to promote and express personal commitment to gender equality around the world, for the benefit of both men and women. Sheryl Sandberg's *Lean In: Women, Work, and the Will to Lead* (2013) encourages women to succeed more equally with men in workplaces, by literally and figuratively leaning forward, at the meeting table and within the larger workplace community. Such perspectives have provided fertile ground in the new feminist or postfeminist landscape, gaining much international attention and reverberating in discourses of the nonprofit sector and other spheres, particularly education. However critical perspectives have accompanied this rise in new or post-feminism. Critics contend such discourses offer a deficiency model of gender equality that partly blames women by focusing on their internal change. They also observe in the new landscape tendencies of gender binary essentialism and universalization of women's experiences. Such critical views promote attention to structural and postcolonial contributions to discussions of equity and gender in diverse educational contexts.

Leaning in Versus Structural Gender Inequity

Lean In represents a key text (or texts, as it is expanding in scope and volumes) that exemplifies the emerging postfeminist discourse, becoming a main reference point for addressing gender equity particularly (but not exclusively) in Western societies. *Lean In* has as its main focus the inner world and habits of women and girls. Leaning in as energetic, assertive action is symbolically and

literally recommended by Sandberg. While women can tend to be shy and hesitant while at work, Sandberg argues women must be more proactive in demonstrating commitment and teamwork in order to not be seen as unresponsive, less committed, or less valuable than more vocal and assertive male counterparts. Though Sandberg concedes that external factors also play a role in gender inequity at work, such as sexism or other bias or prejudice, changing larger structures is not emphasized in the text.

In not challenging the status quo or environment, responsibility thus lies with individuals. Women are encouraged to think and be more like men to get ahead. However, critics note that this is at best a partial solution. Successful and assertive men are better liked in workplaces than woman counterparts, as Sandberg acknowledges. Meanwhile women are observed widely to walk a tightrope line to be ambitious without being perceived as pushy, selfish, or bossy, as they are still judged against gendered expectations of nurturance, softness, and sensitivity in work environments. Similar findings have emerged in education, where women continue to be seen as "other" as academics and intellectuals, by both students in teaching evaluations and by colleagues, and face competing pressures to be likable and engage extensively in service and teaching work, while also being assertive and authoritative in order to succeed (Aiston 2011). Such pressures impact employment and promotion in education, reflecting institutional bias rather than personal deficiency of women as individuals. From this perspective, women cannot win simply by acting like men, and women should not be held responsible for gender inequality challenges they cannot resolve single-handedly.

In contrast, He-For-She emphasizes men's roles in gender equity, in higher education, and other spheres, recognizing that women cannot resolve inequality alone. It suggests that it is in everyone's interest to reject a gender binary, in personal interactions and public and professional engagements: through personal pledges and condemnations of gender-based bullying, for example. This reflects an emerging view that the individualistic, masculine-associated traits

associated with Western workplaces and Western education, such as competitiveness, assertiveness, argumentativeness, independence, and rationality, have often been promoted to the neglect of what are seen as feminine traits that should also be seen as valuable in men and throughout diverse organizations. *Quiet* (Cain 2013) acknowledges how the neglect and underestimation of reflective, subtle, introverted, caring, and/or communitarian traits in Western societies (particularly the United States) can harm communities, including professional organizations. Relational approaches to education and policy emphasize how caring for others is essential to well-being despite its irrelevancy to capitalist production or raising scores on standardized tests. Such caring approaches to ethics, often cast as “feminine,” emphasize being attentive, responsive, and respectful to others, interpersonally and globally, as vital practices for aiding others to flourish and for relieving suffering (Noddings 1984). Such views raise awareness that gender equity is not simply a matter of changing women to be like men, as the social conditions of society should be problematized, which enable the unequal status quo.

What Kind of Woman?

In asking women to be confident like men to get ahead, *Lean In* and related discourses also promote gender essentialism, which treats women as naturally more nurturing, generous, and sensitive, and men as more strong, brave, powerful, and shrewd. Yet as Judith Butler (1990) elaborated, we *perform* gender rather than being born with it. Individuals with gender dysmorphia, or who undergo sex or gender changes, vividly demonstrate how gendered traits exist on a spectrum rather than as a binary set of “male” and “female” traits (Feinberg 1993). Their experiences also reflect how men and women face very distinct expectations in the contemporary period, with women experiencing in particular resistance to their expertise and authority based on gender (Feinberg 1993).

Furthermore, postfeminist discourses like *Lean In* reflect white, Western, elite cultural

expectations. Sandberg does not discuss race or class substantively (though she acknowledges that women of color face worse conditions than white women in her home country, the United States), but her knowledge clearly stems from contexts dominated by wealthy white men. Postcolonial thinkers likewise critique feminism, past and present, as primarily a field of white women who conflate their experiences with those of all women globally. Such gender essentialization produces a status of victimhood upon women, without considering the experiences of non-Western women. At the same time, historical relations have framed “Western” as powerful over the colonial subject. Women of color thus face forms of racial and ethnic oppression that distance them from Western women and unite them more with men in their communities. Though girls and women doubtlessly face challenges across societies and communities, their struggles are not homogeneous worldwide.

Within societies, gender expectations are different across races and ethnicities. Racism and ethnocentrism can play a role in the structure of gender norms and expectations. This gives pause to women of color in joining a universalist, essentializing white feminism, like *Lean In* (hooks 1990). Such assimilatory discourses neglect how women of color are impacted and harmed by expectations based on race and racialized notions of gender. Presumptions of sameness across race and neglect of racialized gender identities are critiqued in postcolonial discussions of voice, wherein women academics of color report pressures to share themselves with white women, educating white women about themselves, instead of engaging in more vital work (Lugones and Spelman 1983). In educational contexts, women of color may also experience a double bind of guilt and pressure from their home communities or families, for changing their culture, if they assimilate to be accepted according to white (or white woman) norms. For instance in higher education, they may face pressure to not appear “too” emotional, passionate, or angry, while acting appropriately assertive and authoritative. Distinctly from white women, women of color are caught between appearing overly passionate or

incompetent. In this context, “leaning in” is less helpful advice and reflects not just expectations to support a male-dominated workplace but also a white-dominated one.

Social class is another factor related to inequity in society and education that intersects with gender (and race). The significance of class is often overlooked in liberal democratic societies and contexts that idealize meritocracy as having eliminated oppressive material inequality. Additionally, class is less visible and more fluid, as education can move one from working class to middle class (Jackson 2014). However, family socioeconomic background correlates with educational attainment, employment in education and other fields, and with the prestige of one’s institutional affiliation and position. First-generation and working-class academics, including white women and women of color, also must adapt to cultural expectations in ways that can stifle their sense of personal identity. One may have to decrease passionate, emotional communication and change their sense of humor. Vocabulary, accent, and dialect become markers of deficiency to hide. As working-class students and academics acquire cultural capital, they can face inferiority complexes or imposter syndrome, recognizing the wealth of knowledge on how to succeed differentially provided to better-off peers and colleagues. As with racialized identity, women academics from disadvantaged economic backgrounds can feel a sense of loss and pressure from family who do not understand the norms and realities of higher education.

Many other factors beyond gender, race, and class impact success in society and education, including sexual orientation, size, age, ability, language, and religion, and so on. Though space does not allow for a comprehensive analysis of such factors, each makes a difference for one’s overall identity and gendered identity, including the way one is expected to communicate verbally and nonverbally and interact with diverse others. However, *Lean In* and related discourses which promote personal responsibility-taking inequality and assimilation to the status quo emphasize traits desired or most effective for white, able, heteronormative, culturally (linguistically and religiously) mainstream, thin, middle-class and

elite-class women, in Western, white, male dominated professional settings. Instead of encouraging women to assimilate within such contexts to get ahead, critics charge that educational and organizational leaders should understand intersectionality of identity (intersecting and inter-related norms and expectations related to social markers like race, class, and gender) and recognize the challenges minorities face.

International Perspectives

Postfeminist discourses such as *Lean In* are also difficult to meaningfully translate across national contexts, despite their increasing global influence and appeal. In the first place, *Lean In* reflects an optimistic, positive psychology-influenced view that is particularly embraced and promoted in the United States. The values associated with this view are not unproblematic, as they can be seen to exaggerate individual responsibility over more balanced views of one’s potential and the possibilities at hand. Realism can be eschewed in favor of idealism despite structural obstacles to enhanced equity for all (Ehrenreich 2010). Such positive thinking can thus lead to neglect of complexity and structural challenges, particularly in aspects of social life such as the economy. Evidence about the power of positive thinking in areas of life like medicine and employment (i.e., staying optimistic in order to enhance health or get a job) remains inadequate, while motivational speakers and coaches sell guidebooks and seminars to capitalize on positive psychology’s claims (Ehrenreich 2010).

Furthermore, regardless of the merits and demerits of American values and virtues, smiling, projecting confidence in times of uncertainty, and boasting of oneself are less vital to individual success in international contexts (Gudykunst 2003). First, while a deficiency mentality regarding gender equality reigns in the United States, expectations about gender at work differ across countries. Women in different countries in Africa or Asia may be rewarded less for acting like male counterparts and more for having “feminine” characteristics while at work. Additionally, hierarchy can matter more in non-American contexts

to perceptions of competence and excellence. In many Asian and African contexts, the need for senior colleagues to “save face,” for instance, can limit the value of a junior colleague, regardless of gender, providing feedback casually, with optimism or direct ambition. Such expressions may be a liability in various high-context cultures. Thus, as social relations and identities vary across cultural contexts, leaning in could be a liability in some international environments.

Finally, norms around smiling, emotional expressions, and behaviors representing confidence, such as making eye contact and physically leaning in, also vary internationally (Gudykunst 2003). Productive communication and professional development across cultures should not be reduced to that of the American corporate world, as there are contrasting legitimate and culturally appropriate ways of expressing authority, commitment, responsibility, and other workplace virtues worldwide. Thus, *Lean In* cannot be used prescriptively to enhance gender equity across international contexts. Rather, it should be viewed as an artifact of the white, middle-class and elite corporate United States in the early-twentieth century. Given internationalization of education, it may be useful and productive across educational contexts to examine and explore *Lean In* discursively. Yet, as educational practice must reflect local needs rather than global values to benefit communities, leaning in and embracing American culture should not be endorsed wholesale, to the exclusion of more potentially effective and appropriate programs for enhancing gender equality in specific contexts.

Conclusion

This essay has used the *Lean In* gender equality discourse or movement as an example of the new nonthreatening feminism of the early twenty-first century. It has critically scrutinized its utility in education from an international and postcolonial perspective, considering women across identities and experiences worldwide. Three critiques were explored. The first was that *Lean In* relies on a deficiency model to be unthreatening to the status

quo, wherein women must assimilate to contemporary norms. I argued against such an orientation that women cannot merely assimilate to public norms effectively to achieve equity, because women still face different expectations than men. Furthermore, the value of so-called masculine traits is questionable. A more balanced prioritization of communal values and virtues should be supported, while gender expectations based on a binary view should be problematized. Leaning in is therefore problematic advice, even for white, wealthy women in Western societies, whose challenges to success go beyond their personal attitudes, by a structuralist analysis of the situation.

The second and third critiques focused on the perspectives of women of color and other women facing forms of social stigma and marginalization, as well as women in international environments. For women of color and from disadvantaged family backgrounds (among others), adapting to cultural norms of white middle-class and elite society may carry risks to personal and professional well-being beyond those faced by their white, wealthy counterparts. These include alienation from one's communities and families and the neglect of a more holistic view of their distinctive struggles for equity in society. Women of color are often expected to act differently from white women in the United States, while an intersectional understanding of identity implies we must see all identities as nuanced and dialogically constructed across categories of race, class, gender, language, religion, age, ability, and so on. From an international perspective, norms are also different across countries, with regard to cross-gender professional relations and more broadly understood communication values. This implies that leaning in is in some important ways a cultural and American phenomenon, and should not be held as a universalistic requirement for enhancing gender equity across diverse societies, despite its contemporary resonance in education environments around the world. Instead, educators and women in different societies will profit from considering their own communities and contexts' values and norms in a balanced, more holistic and structural way, in order to develop woman professionals and enhance gender equality and equity in the future.

In sum, leaning in may sound easy – but whether it is worth doing for many women in the world is questionable.

Educational actors, including both men and women, thus might consider *leaning out* away from discourses of individualization, assimilationism, and acceptance of structurally inequitable status quos. Instead of framing difference as deficiency in historically (and contemporarily) male-dominated and white-dominated spaces, diverse professional skills and characteristics should be explored as possible assets that different individuals, groups, and communities may bring to educational and other social environments, in a variety of ways. Rather than expect those victimized by external inequities and biased social norms to adapt, “leaning out” can enable actors and communities to further develop to enhance conditions for greater inclusivity. By leaning out educational and other public leaders can raise awareness of pitfalls of individualization and recognize the potential of alternative models for development not marked primarily by aggression, competition, and individualism but by other important social values, of diversity, pluralism, toleration, and open-mindedness. Thus *Lean In* can be instructive not just as a how-to guide but as a how-not-to guide, as education leaders can explore ways to change conditions to enable equity, rather than blame disadvantaged players for unequal outcomes.

Critical Race Theory: A Marxist Critique

Mike Cole
University of East London, London, UK

Synonyms

Critical race theory; (Neo-) marxism; “Race” over class; Racialization; White supremacy

Two central tenets of Critical Race Theory (CRT) are its advocacy of “white supremacy” as an accurate description of everyday racism and its primacy of “race” over class¹.

“White Supremacy”

Rather than its limited usage to describe only extremist groups today, such as the Ku Klux Klan or hate groups, or realities of antebellum USA, or apartheid South Africa, Critical Race Theory (CRT) employs the concept of “white supremacy” as a descriptor of reality for everyday experiences of racism now. “White supremacy” is seen as a more useful term than racism alone in certain contexts, for example, in the United States and in other specified countries, including the United Kingdom and Australia². This is problematic, both through history and in the present. There are at least seven reasons for this. “White supremacy”:

- Directs attention away from capitalist economics and politics
- Homogenizes all white people
- Inadequately explains non-color-coded racism
- Does not explain newer hybridist racism
- Does not explain racism that is “not white” against “not white”
- Is historically and contemporaneously associated with beliefs and values which are not necessarily associated with “everyday racism,” and historically and contemporaneously connects to fascism, whereas racism and fascism need to be differentiated
- Is counterproductive in rallying against racism

Directing Attention Away from Capitalist Economics and Politics

While, for Marxists, it is certainly the case that there has been a continuity of racism for hundreds of years, the concept of “white supremacy” does

not in itself explain this continuity, since it does not need to connect to modes of production and developments in capitalism. It is true that Critical Race Theorist Charles Mills (1997), for example, provides a wide-ranging discussion of the history of economic exploitation, and that John Preston (e.g., Preston 2007, 2010), writing from within a CRT framework, argues that CRT needs to be considered alongside Marxism. However, unlike Marxism, there is no inherent need to connect with capitalist modes of production or to make links to patterns of migration that are themselves strongly influenced by economic and political dynamics. Thus Gillborn (2008, pp. 34–36) is able to make the case for CRT and “white supremacy” without providing a discussion of the relationship of racism to capitalism. For a full understanding of racism at any given geographical location and/or historical conjuncture, the neo-Marxist concept of racialization is a useful tool.

The Neo-Marxist Concept of Racialization and Institutional Racism

Racialization refers to the categorization of people (falsely) into distinct “races.” The neo-Marxist concept of racialization is distinct from other interpretations of racialization in that it purports that in order to understand and combat racism, we must relate racism and racialization to historical, economic, and political factors.

Specifically, the neo-Marxist concept of racialization makes the connection between racism and capitalist modes of production, as well as making links to patterns of migration that are in themselves determined by economic and political dynamics. Thus the concept is able to relate to these factors, which are the real material contexts of struggle.

Robert Miles, a leading theorist of the neo-Marxist concept of racialization, has defined it as an ideological process, where people are categorized falsely into the scientifically defunct notion of distinct “races” (Miles 1993). Racialization, like “race,” is socially constructed. In Miles’s words racialization refers to “those instances where social relations between people have been structured by the signification of human biological characteristics [elsewhere in the

¹For a more general critique and an appraisal of some aspects of CRT, see Cole 2016a, b, c.

²This entry draws heavily on the Introduction to Cole 2016a, pp. 13–22.

same book, Miles (1989) added cultural characteristics] in such a way as to define and *construct* [my emphasis] differentiated social collectivities” (Miles 1989, p. 75). “[T]he process of racialization,” Miles states, “cannot be adequately understood without a conception of, and explanation for the complex interplay of different modes of production and, in particular, of the social relations necessarily established in the course of material production.” (Miles 1989, p. 7). It is this articulation with modes of production and with the ideological and the cultural that makes Miles’s concept of racialization inherently (neo-) Marxist.

Maria Papapolydorou (2010) has reminded us that for Miles (1989), racism is associated with modes of production but not limited to capitalist modes of production, and that, according to Miles, racialization and racism predate capitalist societies. As Miles puts it, neither are “exclusive ‘products’ of capitalism but have origins in European societies prior to the development of the capitalist mode of production” (1989, p. 99). While this is true, and the Crusades are but one obvious example, the focus here is specifically on the way in which racialization connects to capitalist modes of production (and to patterns of migration). This is not to say, of course, that all instances of racism in capitalist societies are directly or even indirectly linked to capitalism, economics, and politics. In racialized societies, racism is experienced with massive and constant frequency in countless situations, an insistence for which CRT can be credited. The point is that without the neo-Marxist concept of racialization, it is impossible to have a full understanding of racism under capitalism, both historically and contemporaneously. For a discussion of different uses of the concept of racialization, both (neo-)Marxist and non-Marxist, see Murji and Solomos (2005).

Miles insists that we employ the concept of “racialization” rather than “race” to analyze and understand why different groups are racialized in different locations in different historical and contemporary periods and how this all relates to capitalist economic and political processes (Miles 1982, 1989, 1993; Ashe and McGeever 2011).

The UK and the USA are institutionally racist societies. This was recognized officially in the United Kingdom as long ago as 1999 by the Stephen Lawrence Inquiry Report (Macpherson 1999) which followed a lengthy public campaign initiated by the parents of black teenager Stephen Lawrence, after his racist murder in 1993. It needs to be stressed, however, that the resonances in institutional practices of this recognition have now in the United Kingdom virtually disappeared. Institutional racism is defined in the report as:

The collective failure of an organisation to provide an appropriate and professional service to people because of their colour, culture, or ethnic origin. It can be seen or detected in processes, attitudes and behaviour which amount to discrimination through unwitting prejudice, ignorance, thoughtlessness and racist stereotyping which disadvantage minority ethnic people (Macpherson 1999, 6.34).

From a Marxist viewpoint, the nebulous and ahistorical definition of institutional racism provided by Macpherson needs to have historical, economic, and political foci. The definition also requires enhancement by the neo-Marxist concept of racialization. Last but not least, it needs to incorporate intentional as well as unintentional or unwitting racism. Institutional racism can thus be reformulated as follows:

Collective acts and/or procedures in an institution or institutions (locally, nationwide, continent-wide or globally) that intentionally or unintentionally have the effect of racializing, via “common sense,” certain populations or groups of people, through a process of interpellation³. This racialization process cannot be understood without reference to economic and political factors related to developments and changes, historically and contemporaneously, in national, continent-wide and global capitalism. Hegemony describes the ongoing attempts by the ruling class to consolidate a racist consensus. Counter-hegemony refers to continuing resistance to these endeavours.

It should be stressed that the interests of pro-capitalist politicians and capitalists do not always correspond or coalesce around racialization. For

³(Althusser, 1971, pp. 174-175) makes us think that ruling class capitalist values are actually congruent with our values as *individuals* as we are interpellated or “hailed” to think that capitalist values are natural.

example, it is often in the interests of establishment politicians to racialize certain groups of workers, for electoral gain, for example, while capitalists may prefer not to, in their pursuit of cheap labor power and greater surplus value and hence profits. Marxist political economist Gareth Dale maintains that migrant workers are a perfect solution in times of intensified labor market flexibility, but also stresses the contradiction between capital's need for (cheap) flexible labor and the need for hegemonic control of the workforce by racializing potential foreign workers:

On the one hand, intensified competition spurs employers' requirements for enhanced labour market flexibility—for which immigrant labour is ideal. On the other, in such periods questions of social control tend to become more pressing. Governments strive to uphold the ideology of "social contract" even as its content is eroded through unemployment and austerity. The logic, commonly, is for less political capital to be derived from the [social contract's] content, while greater emphasis is placed upon its exclusivity, on demarcation from those who enter from or lie outside—immigrants and foreigners (Dale 1999, p. 308)

The Homogenization of All White People

Mills acknowledges that not "all whites are better off than all nonwhites, but ... as a statistical generalization, the objective life chances of whites are significantly better" (Mills 1997, p. 37). To take poverty as one example, poverty for white people is consistently less than that of racialized peoples. Nevertheless, we should not lose sight of the life chances of millions of working-class white people who, along with racialized groups, are part of the 99%, not the 1%.⁴

Moreover, the term "white supremacy" at least *implicates* all white people as part of some hegemonic bloc of "whiteness." For Mills (1997, p. 1), "white supremacy" is "the basic political system that has shaped the world for the past several hundred years" and "the most important political system of recent global history," while the racial

contract⁵ "designates Europeans as the privileged race" (p. 33). To underline the point that he sees "white supremacy" as a political system in its own right, and that the racial contract is both "real" and "global" (p. 20), Mills asserts:

Global white supremacy ... is *itself* a political system, a particular power structure of formal or informal rule, socioeconomic privilege, and norms for the differential distribution of material wealth and opportunities, benefits and burdens, rights and duties (p. 3).

Some critical race theorists argue that "white supremacy" does not necessarily refer to skin color, "rather to structures of subordination and domination." However, "white supremacy" is generally perceived as referring to skin color.

Inadequate Explanation of Non-Color-Coded Racism

Mills acknowledges that there were/are what he refers to as "'borderline' Europeans" – "the Irish, Slavs, Mediterraneans, and above all, of course, Jews," and that there also existed "intra-European varieties of 'racism'" (Mills 1997, pp. 78–79). However, he argues that, while there remain "some recognition of such distinctions in popular culture" – he gives examples of an "Italian" waitress in the television series *Cheers* calling a WASP character "Whitey" and a discussion in a 1992 movie about whether Italians are really white (p. 79) – he relegates such distinctions primarily to history. While Mills is prepared to "fuzzify" racial categories (p. 79) with respect to "shifting criteria prescribed by the evolving Racial Contract" (p. 81) and to acknowledge the existence of "off-White" people at certain historical periods (p. 80), he maintains that his categorization – "white/nonwhite, person/subperson" – "seems to me to map the essential

⁴"We are the 99%" is a widely used political slogan, first coined by the Occupy movement (www.occupytogether.org/aboutoccupy/).

⁵Mills's "racial contract" refers to his belief that racism is at the core of the "social contract," rather than being an unintended result, because of human failing. Social contract theory, which is nearly as old as philosophy itself, is the view that people's moral and/or political obligations are dependent on a contract or agreement among them to form the society in which they live (Internet Encyclopedia of Philosophy (IEP), www.iep.utm.edu/soc-cont/).

features of the racial polity accurately, to carve the social reality at its ontological joints” (p. 78).

Mills is, of course, writing about the United States, and his analysis does not provide an explanation for non-color-coded racism in the United Kingdom, where there are well-documented analyses of such racism both historically and contemporaneously (see Cole 2016a, chapter 1).

Robert Miles *is* aware of non-color-coded racism. He stresses that racialization is a process and recognition that “opens the door to history” which subsequently “opens the door to understanding the complexities of who gets racialized when and for what purpose, and how that changes through time” (in Ashe and McGeever 2011, p. 2019). Miles warns against avoiding the “fundamental mistake” of drawing clear lines between what happens to white immigrants and black immigrants, adding that the “black–white” dichotomy leads you into a “huge cul-de-sac” (in Ashe and McGeever 2011, p. 2019). “White supremacy” provides no basis for an understanding of racism in the UK directed at the Irish people, at Jewish people, at Gypsy, Roma, and Traveller communities, or of the widespread xeno-racism directed at Eastern European migrant workers since Poland joined the European Union (see Cole 2016a, chapter 1). This racism has all the hallmarks of traditional racism, such as that directed at Asian, black, and other minority ethnic workers following mass immigration after the Second World War, but impacts on recently arrived groups of people.

No Explanation of Newer Hybridist Racism

Under this heading, anti-asylum-seeker racism and Islamophobia are included. “Newer hybridist racism” is used because, unlike the forms of racism that are either essentially color-coded or essentially non-color-coded, anti-asylum-seeker racism and Islamophobia can be either color-coded or non-color-coded. These forms of racism can also encompass a combination of color-coded and non-color-coded racism. For example, racism directed at asylum seekers from “sub-Saharan Africa” (itself a term with color-coded racist implications) will be color-coded but may also be Islamophobic, which is not necessarily color-

coded, or it may be a combination of color-coded (anti-black) racism and non-color-coded racism (Islamophobia). That form of racism, experienced by Afghan and Iraqi asylum seekers, for example, is also ambiguous and may or may not be more Islamophobic than color-coded.

Lack of Explanation of Racism That Is “Not White” Against “Non-White”

Charles Mills acknowledges that “white supremacy” does not explain “varieties of racial domination . . . that are not white-over-non-white,” and “that is a weakness of the term that should be conceded” (Mills 2009, p. 275). He gives the example of “certain Asian nations.” In late 2015, Islamophobia in Myanmar (Burma) is an obvious example, and anti-Vietnamese racism is rife in Cambodia. Not-white over non-white racism is also a reality in South Africa. However, it has to be said that interethnic racism is also a reality in the “developed world.” For example, in the overtly xeno-racist UK Independence Party (UKIP) there are black and Asian members and supporters.

Historical Context, Historical and Contemporary Association with Other Beliefs and Values, and Connections with Fascism

First of all, it needs to be pointed out that in certain periods of history “white supremacy”, conventionally defined, was the norm. Second, white supremacist groups, conventionally defined, have tended to embrace a number of other beliefs and values which are not necessarily associated with everyday racism. These can include homophobia, Holocaust denial or claims that the Holocaust was exaggerated, antisemitic conspiracy theories (that Jewish people conspire to control the world), and engagement in military-type activity.

Some of these associated beliefs and values were epitomized by the now almost defunct white supremacist and fascist British National Party (BNP). When its then leader Nick Griffin appeared on the popular BBC discussion program, *Question Time* in October 2009, he stated that Islam was incompatible with life in Britain, admitted sharing a platform with the Ku Klux

Klan, and described gay men kissing in public as “really creepy.” He said that “legal reasons” prevented him from explaining why he had previously sought to play down the Holocaust, and that he had now changed his mind. He was challenged by fellow panelist Jack Straw, the then Justice Secretary, who said there was no law preventing him from giving an explanation.

It is important to distinguish between racism on the one hand and “white supremacy” and fascism on the other. Aninda Bhattacharyya (2009) succinctly explains the relationship between capitalism and fascism. As he puts it, “fascist organisations offer themselves to the ruling class as a deadly weapon to use against the left. But the use of this weapon comes at a price – stripping away any pretence that capitalism is a fair or progressive system.” This is because fascism means that the ruling class has to use the full force of the repressive apparatuses of the State (RSAs) rather than just rely on the ideological State apparatuses (ISAs) (Althusser 1971). Thus fascism is “a weapon of last resort for our rulers, one that they turn to in periods of acute crisis but keep their distance from at other times” (Bhattacharyya 2009). In other words, while the ruling class is quite happy to up the barometer of racism, it tries hard not to admit to doing that:

The contradictory political relationship between the ruling class and fascism manifests itself as a contradictory ideological attitude and contradictory action. So the *Daily Mail* [a right-wing tabloid, aimed at the UK middle class] attacks Muslims, but also attacks the BNP for attacking Muslims. The mainstream parties denounce the BNP, but play to its agenda on issues like immigration (Bhattacharyya 2009)⁶.

Fascism tends to have both a parliamentary and a street presence. This is typical of fascist complementarity and dates back to Benito Mussolini, fascist dictator in Italy in the 1920s, 1930s, and 1940s (he had the *squadre d'azione*), and Adolf Hitler, who had the “Brownshirts” who played a major role in his rise to power in the 1920s and

1930s (Smith 2010, p. 13). Antiracists, including Marxists, need of course to “oppose both fascism and the racism that feeds it, both politically and on the streets, while understanding the distinctions and relationships between them” (Bhattacharyya 2009). Bhattacharyya concludes:

That means understanding that the “right wing anti-fascism” of [sections of the media] isn’t simply a matter of hypocrisy. There are material political motives for why the ruling class is ordinarily opposed to fascism ... [but we] cannot ever rely on this right wing anti-fascism that can rapidly reverse into support for the Nazis (Bhattacharyya 2009).

CRT obfuscation of “white supremacy” and its collapse into the realm of “everyday racism” critically undermines a serious analysis of “white supremacy” in the conventional use of the term, and its connections to other obnoxious beliefs, values, and actions, and to fascism.

“White Supremacy” as Counterproductive in Rallying Against Racism

As the crisis in capitalism deepens, it is absolutely essential for unity among the working class as a whole. Advocating “white supremacy” as a descriptor of “everyday racism” is useless as a unifier and counterproductive as a political rallying point. While the prospect of social revolution and socialism in the UK and the USA is off the agenda for the foreseeable future, it is inconceivable, in my view, that workers, racialized or not, could productively unite around anti-“white supremacy.” More constructive, from a Marxist perspective, is to demand an end to racialized capitalism.

Critical Race Theory and the Primacy of “Race” Over Class

Mills rejects both what he refers to as the “original white radical orthodoxy (Marxist)” for arguing that social class is the primary contradiction in capitalist society and the “present white radical orthodoxy (post-Marxist/postmodernist)” for its rejection of any primary contradiction. Instead, for Mills, “there is a primary contradiction, and ... it’s race”

⁶This was also the case with the xeno-racist political party UKIP in the run-up to the 2015 UK general election (see Cole 2016a, pp. 67–83 for a discussion).

(Mills 2003, p. 156). For Kimberlé Crenshaw and colleagues (1995, p. xxvi), “subsuming race under class” is “the typical Marxist error.”

Mills states that “[r]ace [is] the central identity around which people close ranks” and that there is “no transracial class bloc” (Mills 2003, p. 157). Given the way in which neoliberal global capitalism unites capitalists throughout the world on lines that are not necessarily color-coded, this statement seems quite extraordinary.

“Race,” Mills goes on, is “the stable reference point for identifying the ‘them’ and ‘us’ which override all other ‘them’ and ‘us’ (identities are multiple, but some are more central than others)” (p. 157), while for Crenshaw and colleagues (1995, p. xxvi), although they acknowledge that “race” is socially constructed (an issue addressed earlier in this entry), with which Marxists would fully concur, “race” is “real” since “there is a material dimension and weight to being ‘raced’ in American society.” It is the case, of course, that racism has real material effects on racialized peoples. “Race,” Mills (2003, p. 157) concludes, is “what ties the system together, and blocks progressive change.” For Marxists, it is capitalism that does this.

Mills invites readers to:

Imagine you’re a white male Marxist in the happy prefeminist, pre-postmodernist world of a quarter-century ago. You read Marcuse, Miliband, Poulantzas, Althusser. You believe in a theory of group domination involving something like the following: The United States is a *class* society in which class, defined by *relationship to the means of production*, is the *fundamental* division, the bourgeoisie being the *ruling* class, the workers being *exploited* and *alienated*, with the state and the juridical system *not* being neutral but part of a superstructure to maintain the existing order, while the *dominant ideology* naturalizes, and renders invisible and unobjectionable, class domination (Mills 2003, p. 158).

This all seems a pretty accurate description of the United States in the twenty-first century, but for Mills it is “a set of highly controversial propositions” (p. 158). He justifies this assertion by stating that all of the above “would be disputed by mainstream political philosophy (liberalism), political science (pluralism), economics (neoclassical marginal utility theory), and sociology (Parsonian structural-functionalism and its

heirs)” (p. 158). While this is true, my response to this would be, well, of course it would be disputed by mainstream philosophers, pluralist political scientists, neoclassical economists, and functionalist sociologists, all of whom are, unlike Marxists, at one level or another apologists for capitalism.

Social class, albeit massively racialized⁷, is the system upon which the maintenance of capitalism depends. It is possible, though extremely difficult, because of the multiple benefits accruing to capital of racializing workers (not least forcing down labor costs) and the unpaid and underpaid labor of women as a whole, to imagine a capitalist world of “racial” (and gender) equality. It is not logically possible for capitalism to exhibit social class equality. Without the extraction of surplus value from the labor of workers, capitalism cannot exist.

Capitalism is dependent on racism both as a source of profiteering (in general appropriating more surplus value from racialized workers) and as a means of “divide and rule,” driving a wedge between nonracialized and racialized workers. These processes of “divide and rule” were recognized by Marx, some 145 years ago:

In all the big industrial centres in England there is profound antagonism between the Irish proletariat and the English proletariat. The average English worker hates the Irish worker as a competitor who lowers wages and the standard of life. He feels national and religious antipathies for him. He regards him somewhat like the poor whites of the Southern states regard their black slaves. *This antagonism among the proletarians of England is artificially nourished and supported by the bourgeoisie. It knows that this scission is the true secret of maintaining its power* (my emphasis) (Marx 1870 [1978], p. 254).

That is one of the reasons why combating racism is so crucial for Marxists. As Keenga-Yamahtta Taylor puts it, without “a commitment by revolutionary organizations in the here and now to the fight against racism, working-class

⁷Social class is of course also gendered, and there is a substantial and substantive literature on Marxism and feminism, the latest of which is Mojab (2015). Many feminists have rejected Marxist feminism in favor of intersectionality (see Cole 2016a, pp. 22–23).

unity will never be achieved and the revolutionary potential of the working class will never be realized.”

Critical Self-Learning and Organizational Learning: A Popperian Perspective

Stephanie Chitpin

University of Ottawa, Ottawa, ON, Canada

Introduction

People who are interested in teaching and learning are also interested in professional growth and development (Swann 2012). These people, often referred to as “educators,” frequently assume that learning occurs when information is received by the learner (Popper 1994; Swann 2012). Debates about learning center mostly on how information received by the learner is processed. Even constructivists are of the view that learning takes place when the learner is actively constructing meaning from the information received, based on his or her previous experience (Dewey 1938; Vygotsky 1978). If educators assume that learning is a process that begins with the

internalization of information received, they are more inclined, then, to discuss learning from a psychological perspective rather than from a philosophical one (Vygotsky 1962).

The intention, here, is not to underplay the importance of psychology when it comes to the factors that affect individual or group learning but, rather, to emphasize the danger of overlooking important philosophical assumptions about learning. Expectations of learners are linked to assumptions about learning, that is, to philosophical assumptions about the nature of learning. For example, what factors contribute to learning when learning takes place (Swann 2012)?

The purpose of this entry is to discuss the term “learning” from a philosophical perspective. Learning, in this sense, refers to a subjective process where individuals learn in a social context rather than through the accrual of knowledge and information in its broader sense. The argument presented in this entry is based on Sir Karl Popper’s evolutionary analysis of learning (Popper 1974, 1979, 1994, 1999 and also Popper and Eccles 1977).

This entry begins with a discussion on competing theories of learning. It features Popper’s evolutionary analysis of learning and the nature of learning. The paper ends with an illustration of how learning through trial and error provides teachers with opportunities to challenge, discuss, and question their assumptions or theories, as well as to experiment with solutions to problems they encounters in their teaching practices.

Two Competing Learning Theories

There are two major competing learning theories. One states that “learning never involves the absorption of informational elements from outside the learner,” while the other states that “some learning involves the absorption of informational elements from outside the learner.” Popperian selectionism is closely aligned with the first statement and is also consistent with the work of psychobiologist Friemuth Petersen (1988, 1992, 2000) and neuroscientists such as Edelman (1992) in regard to brain functioning. However, the work of Petersen and Edelman does not refute the notion that “some

learning involves the absorption of informational elements from outside the learner.” This is due to the fact that – as with the statement, “Learning never involves the absorption of informational elements from outside the learner” – neither the theory nor the statement can be refuted or falsified. This is because, even though there is potential for some observable outcomes – which is learning – one cannot observe the core process to which these statements refer (Swann 2012). However, this does not mean that the unfalsifiable theory is either accepted as fact or is considered to be weak. Some theories are intrinsically unfalsifiable, but they can still be discussed and defended (Popper 1979).

Popper’s Evolutionary Analysis of Learning

Popper’s evolutionary analysis of learning states that not all informational elements are transferable from the environment to the learner. He further states that, “We do not discover new facts or new effects by instruction or by the environment” (Popper 1994, p. 47). In other words, Popper claims that there is no transfer of information from one individual to the next or from the physical environment. However, this does not mean that learning does *not* take place in response to instruction. Learning can take place when learners are instructed, as can be observed in schools where teachers give instruction and student are expected to learn. Learning in response to instruction and learning by instruction are not synonymous (Swann 2012). Learning, in response to instruction, does not create knowledge; rather, learning takes place by means of the activity of the learner. That is, *we learn by instruction only insofar as we instruct ourselves – we learn by instruction from within*. In fact, numerous empirical studies support this view (Gray 2004; Norretranders 1998).

To facilitate a common understanding of the meaning of the evolutionary analytical sense, the term “learning” denotes “expectation, problem, knowledge, and criticism” (Swann 2012). The use of the term “expectation” is not restricted to situations where a person is expecting or anticipating something. Expectation can have the

negative connotation of disappointment in one's expectation of something or someone. When one is disappointed, only then can the expectation come to one's attention. As Popper (1979) puts it:

We become conscious of many of our expectations only when they are disappointed, owing to their being unfulfilled. An example would be the encountering of an unexpected step in one's path: it is the unexpectedness of the step which may make us conscious of the fact that we expected to encounter an even surface. (p. 344)

Also, for the purpose of this paper, the term learning is used to mean "corrections or elimination of certain expectations" or errors (Popper 1979).

The Nature of Learning

According to Popper's evolution of learning, the difference between an organism that learns and one that does not is that the former develops within his or her context of experience or dispositions. Dispositions are not to be taken to mean an outcome of genetic inheritance or haphazard organic change (Popper 1979). Rather, in this paper, dispositions refer to teachers' dispositions to react to their unfulfilled expectations of some sort, such as the expectation that, by grouping students homogenously, stronger students would be able to take a leadership role in helping weaker students. When teachers adopt this strategy, they may find that not all students work cooperatively and effectively, which may result in some disappointment or errors in their expectation. Thus, one may note a change in learning by way of teachers' expectations. It is the disappointment of expectations, in this case, the results from homogenous grouping that drives teachers' learning.

A teacher's ability to learn is a specific form of adaptability. This ability to adapt has a potential evolutionary advantage. One may argue that the more experience one has, the fewer errors or mistakes one makes. However, based on Popper's evolutionary analysis of learning, learning does not depend totally on maturation; a learning organism will continue to develop new expectations, preferences, and capabilities that enables her to function more effectively in whatever situation she finds

herself (Swann 2012). For example, a teacher who achieved mastery of how to use assessment of learning to inform parents and administrators as to whether her students have learned, and whether the standards have been met, may find that she needs to focus her attention on selecting, identifying, or grouping students for certain educational paths or evaluating the effectiveness of her instructional methods (O'Connor 2009).

From an evolutionary learning perspective, this does not mean that what the teacher is learning is a desirable goal for the system. It is useful to distinguish between progress and progression (Munz 2001). Progression involves moving from one state of affairs to another, whereas progress involves moving from one state of affairs to a better one (Swann 2012). Learning involves progression in that the learner moves from one expectation to another, as in the case of the teacher who decides to focus on evaluating the effectiveness of her instructional skills once she has a good understanding of the curriculum content. However, not all learning is desirable or "good" in the sense that the more one learns, the better it is. For example, a new teacher learns from a veteran teacher that using grades as a weapon to make students comply with her requests to either behave appropriately in class or to turn in their assignments on time, or suffer the consequences of receiving a failing grade, is detrimental to the student-teacher relationship (Guskey 1996). This case further illustrates that the students in question may start out in school believing that they are capable of learning. However, as a result of how the teacher has used a punitive measure (grading) to enforce compliance in submitting assignments on time, students may learn to see themselves as not being able to learn. Although the students may still have the potential to learn, their belief in that potential is diminished as a result. While there may be development in expectations, there is no progress. In fact, what is observed is an impediment to future learning (Chitpin 2013; Swann 2012).

Social constructivists strongly believe that learning is inherently social, as learners engage in dialogue with others (Bruner 1994). There is little argument that individuals learn in a social context and engage with linguistically formulated

problems, theories, hypotheses, arguments, etc. (Swann 2012). However, one cannot deny that learning is an activity that takes place at the individual rather than at the group level.

Learning takes place “when our knowledge bumps up against our ignorance” (Burgess 2000, p. 54). When an expectation, as in the case of the teacher who expects her students to post online the analysis on their weekly readings, is faced with the challenge that not all of her students are following the assessment criteria she has set, the teacher may realize that something is not working well. Learning takes place when she decides to either modify her expectations or replace them with new ones. She is entirely responsible for modifying and replacing the expectations.

One can also say that the medium or the context (online) has acted as an eliminatory control and a resource for the teacher. Although the context cannot transfer data to the teacher, the “quality” of the context is very important, as it provides scope by which the teacher can learn. Regardless of what the teacher does to promote learning – that is, by having her students post their critical analysis on Blackboard Learn – it does not mean that any informational elements of the readings (theories, concepts, preferences) have been transmitted to all students. Instead, the teacher must do something to engage her students in trial and error elimination to provoke change. For example, the teacher may say that her colleague told her that asking students to do a weekly critical analysis is an effective way to ensure that all students are doing their readings and that, consequently, they understand the materials. But, when the teacher implements the strategy, she finds out that not only are some students not posting their critical analyses but that they are not, in fact, understanding the material. Much of what is happening with the students will remain unexplained, as one does not know why they are not posting their critical analysis – is it because of lack of time or lack of interests? By means of instruction, some of the students may learn what the teacher has intended, but it is a very hit-and-miss affair, and, thus, it is important that educators explore the method of learning through error elimination.

Learning Through Error Elimination

According to Popper’s evolutionary analysis of learning, all learning embodies the same process of error elimination. The process of error elimination is summed up in the following schema: $P1 \rightarrow TS \rightarrow EE \rightarrow P2$.

P1 represents an initial problem and TS is a tentative solution that is applied to solve the problem. EE stands for error elimination, the means by which some tentative solutions are eliminated through criticism, which, in turn, gives rise to a new problem, P2. Popper’s schema is useful in providing an explanation of what happens whenever learning takes place.

To illustrate how this schema works, a problem needs to be created; for example, a teacher teaching an online course may wish to work on increasing her students’ online participation. Her initial problem (P1) may be formulated as: How does one increase student participation online? Her tentative solution (TS): students are required to post their analysis of the course weekly reading as part of the participation mark (Chitpin 2015). The students may not have behaved the way she expected; that is, instead of posting their analysis, some of them provided short comments on the analysis of others. This behavior can be formulated as a problem of “how to get all students to post their weekly analysis.” The above example illustrates the mismatch between expectation and experience, and, granted that not all mismatches are equals, some turn into problems and others do not. For a teacher to have a problem, she needs to be dissatisfied implicitly or explicitly with a state of affairs in which she finds herself, as in the above example. If she is sufficiently dissatisfied with this state of affairs – how does she grade those students who did not post a critical analysis? Her problem of overcoming this dilemma does not come automatically from her observation that not all students are posting a critical analysis. She might make a note and do nothing about it or she might choose to focus on the problem.

There are many possible solutions or ways she could respond to her problem, even though she can only adopt one tentative solution at a time. For example, she might solve this problem by

changing the criteria of her participation mark to allow students to either post their analysis or comment on the analysis or analyses of others or by assigning a zero for those not meeting the criteria of the assessment procedure stated in the course syllabus. She could choose the former or the latter, and one of these solutions may be more successful than the other one, depending on the context.

Each of her tentative solutions is also laden with expectations about what it can do to solve the problem. These expectations may be false or inadequate in solving the problem. One of the tentative solutions may be better or more progressive than the others. Better or progressive is judged according to whether or to what extent the problem is solved and what additional consequences ensue. For example, the teacher may change the criteria of the participation mark to responding to comments *or* posting critical analysis only to find that the comments posted are short and imprecise. A solution is always a trial, and there is no way for the teacher to know in advance whether changing the criteria to accommodate the students is the best solution to her problem.

Popper (1992) says that all trials “are blind to the solution to the problem” (p. 46). There is no secure way of knowing what the consequences of choosing one action over the others will be (Miller 2006), but a disposition to react in one way may be the best survival strategy for that situation or circumstance. Error elimination (EE) is the elimination or the modification of an expectation, theory, solution, behavior, or hypothesis, as in the case of the teacher who needs to change her participation mark criteria to deal with her problem, that of “how to get students to post their critical analysis.” Popper (1979) defines error elimination as:

New reactions, new forms, new organs, new modes of behavior, new hypotheses, are tentatively put forward and controlled by error-elimination... Error-elimination may proceed either by the complete elimination of unsuccessful forms (the killing-off of unsuccessful forms by natural selection) or by the (tentative) evolution of controls which modify or suppress unsuccessful organs, or forms of behavior, or hypotheses. (p. 242)

The process of error elimination functions as a feedback loop and also acts as problem-solving tool. It is continuous and often unconscious (Swann 2012). Problem (P2) emerges from a process of trial and error elimination, which is different from the initial problem (P1). Once the teacher attempts to solve her problem of “how to get her students to post their critical analysis,” the tentative solution exists in the history of the situation, and whether or not the teacher has learned, a new state of affairs has been brought about. This new state of affairs will present further challenges for the teacher, which may lead to a series of new problem and new tentative solutions. The process continues until a reasonably satisfactory resolution is achieved.

Conclusion

Throughout this entry, Popper’s evolutionary analysis of learning has been described, and examples that “learning never involves the absorption of informational elements from outside the learner” have been evidenced. If one is committed to advancing learning, one must search for errors and limitations in one’s solutions to practical problems. Efforts need to be made to develop practices and ideas that are new and, as Popper (1979) says:

The process of learning, of growth of subjective knowledge, is always fundamentally the same. It is imaginative criticism. This is how we transcend our local and temporal environment by trying to think of circumstances beyond our experience: by criticizing the universality, or the structural necessity, of what may, to us, appear (or what philosophers may describe) as the ‘given’ or as ‘habit’; by trying to find, construct, invent, new situations – that is, test situations, critical situations, and by trying to locate, detect, and challenge our prejudices and habitual assumptions. (p. 148)

Society views criticisms or mistakes as being wrong, and these often come with explicit statements of disapproval or rejection. However, this is a narrow and inappropriate view, as each offers an opportunity for improvement. If one begins viewing criticisms as something that lead an individual to improve the situation, then there are benefits. No matter how

valid a criticism is, it should not stifle individual creativity nor inhibit subsequent error elimination.

Critical Theory as Metatheory of Education

Introduction

Critical theory of education can be understood as essentially a specific kind of philosophical project, in which the question of the conditions of the possibility of knowledge is taken as at once conceptual and social. Whereas pedagogy or educational theory focuses on the actual acquisition of knowledge and inculcation of certain desired or desirable dispositions (i.e., the conditions for teaching and learning), a philosophical or “critical” project is to examine the conditions of possibility for such a systematic knowledge as that which educational theories claim for themselves. In other words, the aim is to examine the very premises upon which educational theory and practice are based. While educational theories, however abstract, belong broadly to the empirical sciences and, more specifically, the social sciences, the critical project is “metatheoretical,” to the extent that it addresses the very principles that constitute any theory of education as a science or program of systematic study. Critical theory of education goes beyond the practical disciplines concerned with methods for achieving particular aims (such as psychological theories, for instance) and seeks theoretical grounding in a thorough critique of the tacit assumptions, aims, and methods of all educational ideals and practices. This tradition of ideology critique, stemming from the critical theory of the Frankfurt School, addresses the function of teaching and learning as consequent upon the social nature of the ostensible knowledge, understanding, and/or dispositions that are to be attained. All the data assembled and interpreted in empirical social science must be critically theorized. The strict methodologies and regulated experiments of empirical study of social phenomena can never replace critical reflection, for the simple reason that all observation already assumes a theoretical framework, itself the result of certain historical conditions, which can and ought to be made explicit, critiqued, and normatively assessed, that is, evaluated from the perspective of human agency and emancipation. In this respect, “critical theory” is always already “metatheoretical” in the sense that it is theorizing about theory as much as of practice. Behaviorist

theoretical frameworks for the study of education, for instance, and the models issuing from them, which have long exercised a powerful influence on the curriculum field, were in part adapted from Taylorism (the scientific management movement of the 1920s). The task of critical theory here then would be to subject behaviorism as both theory and a practice to critical reflective analysis.

Education, Ideology and Autonomy

One of the characteristic features of critical theory is its recognition of the emancipatory potential of Enlightenment ideas and ideals, even as it analyzes the destructive force of its militant objectivity. From this perspective, in the guise of liberal notions of economic growth and scientific progress, the memory of the subjective experience of intrinsic value as distinct from exchange values is obliterated, and noninstrumental relations between people as well as between human beings and nature (the subjective, the transcendent) are eradicated (“For enlightenment, anything which does not conform to the standard of calculability and utility must be viewed with suspicion” Adorno and Horkheimer, 2002). The Frankfurt School, following Marx, stressed culture as a tool of class and social reproduction and therewith also tended to focus on the power of capital over and above human agency. Adorno and Marcuse saw the advent of mass culture as a function of the accumulation and expansion of capital into the minutiae of everyday life, that is, of the colonization of the private sphere by the marketplace. For Marcuse, modern liberal society is characterized by “democratic unfreedom,” an historical situation in which the forces of domination go unrecognized and therefore uncriticized (Marcuse 1964). In that respect, capitalism is totalitarian in much the same way as communism and fascism. In the case of late capitalism, the tendency is to “industrialize the mind,” just as the production of goods was industrialized during the heyday of capitalism. In Adorno’s view, following Weber, rationalization has led to human thinking becoming increasingly automated (Weber 1946): a mechanized, segmented, and debased instrument that has lost its capacity for critical thought, that is, to confront

and evaluate its immediate circumstance (to recognize the contradictions in its way of life). In this respect, the all-encompassing ideology of the market constitutes a “prohibition on thinking itself” (Adorno, as cited in Giroux 2001).

In educational theory, thinkers taking their bearings at least in part from the Frankfurt School (Freire, Giroux, *inter alia*) try to negotiate between the recognition of the Marxist distinction between the economic base and the superstructure, where the latter is often the umbrella term for all cultural expressions and artifacts (law, religion, art), and the desire for the realization of the possibility of genuine autonomy as something more than liberal romanticism or utopianism. While they will grant that material social practices sustain capitalist relations, those who work within the tradition of critical educational theory want to retain what is instructive and constructive in the Kantian ideal of Enlightenment and the centrality of the spontaneous activity of the thinking and perceiving subject (Kant 1965), that is, the thought that education, by cultivating genuine autonomy in the individual, develops his capacity to see beyond the socially given and beyond his own immediate situation, and thus to contribute to a happier future for humanity. For Kant, education is simply sowing the seeds of Enlightenment: an ongoing and unending projection into the future. But while Kant sees the possibility for a common future in the activity of the autonomous subject, critical theorists tend to side with Marx in viewing subjectivity as first and foremost a product of social relations. Education, in the sense of formal schooling, on this view, needs to be analyzed in terms of the assumptions built into mainstream curricula, where the latter are often taken as ideologically neutral attempts at social engineering to produce desired discrete behaviors. From the point of view of critical theory, however, school curricula ought to be studied as agencies of socialization (Giroux 2001). Along with providing pupils with definite goals and teachers with explicit objectives for instruction, the curriculum transmits and generates beliefs and values tacitly through the routines and language of everyday experience in school. Thus, on the one hand, there is the structural question concerning the material and organizational conditions for education, and, on the other,

the concrete, subjective experience of those conditions in actual cases of teaching and learning. A critical analysis has therefore to distinguish between educational ideologies and institutional reality, that is, how those ideologies come to expression and use in actual practice.

Education is part and parcel of existing social, economic, and political regimes, and its institutions are involved in the production and reproduction of determinate forms of subjective experience (through covert as well as overt socialization with regard to values and beliefs). The commonsense assumption that there is some sort of neutral position from which various technologies of education can and ought to be derived is itself thus based on certain ideological assumptions that can be subjected to critique, since what is at stake are not merely different responses to the demands placed on educational institutions and practices, but the value-laden language governing what questions are possible to ask and what sorts of answers are conceivable in that language, *i.e.* ideology. A conservative position on education embraces the fundamental role of schooling in the acquisition and appropriation of societal norms and values as a positive function (by engendering and maintaining consensus, cohesion, and stability). A liberal view focuses on the importance of the role of intentionality and interpersonal relations and stresses reform of individual practices, without regard for the material base of education, that is, it ignores the way in which structural constraints in society are reproduced in the activities of educational institutions, students, and teachers. The responsibility for deficiencies is placed on the individuals acting in the concrete situation, rather than on the conditions that create the situation in the first place. Critical theories of education tend to focus on the manner in which social and class divisions necessary for the production and legitimation of capital and its institutions are reproduced in the educational institutions and practices in which students are prepared for different positions in a stratified labor force. At the same time, certain versions of critical theory question the monolithic picture of totalitarian structures in which agency, both individual and collective, is portrayed as impossible, not merely in fact, but almost in principle (Giroux 2001).

A philosophical theory, a philosophical theory of dialectical critique in this context would begin with a thorough interrogation of unquestioned received truths and social practices that masquerade as the discourse of objectivity and neutrality: the recognition of the non-identity of one's reason and existent social reality. Critique would then uncover the incongruence in certain forms of discourse, action, and experience and reveal their social function (e.g., how they can both be forms of resistance to hegemonic modes of behavior, and as such expressions of freedom, while at the same time work to further limit one's own agency or the self-activity of others). Education can be ideological indoctrination in the sense of the production and effectuation of distorted meaning, but it can also, in a Kantian vein, promote critical thought and action. According to Adorno, the truth in the concept of subjective experience is the acknowledgement of the subject as an inalienable moment in cognition. Ideology critique is concerned with more than showing how certain ideologies function; it is about discerning the contents of those ideologies and making judgments. Marcuse points to how human relations are subjected to forms of calculability and control and made to appear as objectified relations between objects instead of as social relations between subjects. The historical connections and contingencies leading up to the status quo are forgotten, and surface phenomena (habits, routines) are perceived and treated as immutable social or even natural facts. This is related to what Adorno refers to as the "mythical" quality of Enlightenment. In Marcuse's view, since even individual needs are historically conditioned, they are alterable. In fact, certain kinds of needs (such as meaningful social relations) are even liberating, insofar as they contradict the conditions that inhibit their fulfillment.

The concept of ideology critique at work in the thought of the Frankfurt School thus provides a general framework for educational theory insofar as it promotes an agenda of demystification by uncovering the genealogy of certain patterns of speaking and thinking with regard to the form and content of instruction, the interests motivating them, and the logic of the practices informed by them, as well as tracing these patterns in the

processes of subjectification involved in any program of education (Giroux 2001). (While the issue cannot be adequately addressed here, it may be noted that certain formulations of this agenda raise a philosophical problem as to the rationale for treating all thought and action as results of sedimented history amenable to the methods of ideology critique except the method of tracing itself, which is treated as historically self-conscious and unassailable). Ideology critique monitors the relationship between hegemonic ideologies and unreflective human language and behavior and thus has implications for educational theory to the extent that it brings to light the emancipatory or repressive interests served by the sedimented routines and protocols, as well as the automated language, involved in institutionalized teaching and learning.

An important component in the dismantling of the ostensible neutrality and necessity of the given, as something fundamentally separate from the processes and conditions of its production, is to notice that this notion of neutrality shares the form of the logic of commodification. What are in fact practices developed under specific conditions to serve certain interests appear objectified in the immediacy of everyday discourse and "common sense." For the Frankfurt School, it will be recalled, the task of theory is to identify the socio-historical interests involved in common sense, or unreflective awareness and automated speech, and identify the functions served by the obvious "truths" emanating therefrom. Such a move highlights the intimate relationship between language and knowledge, fact and value. The presumption that such distinctions are themselves universally valid is, on this view, itself a piece of distorting ideology or mystification, since it conceals the human agency involved in the production of knowledge or facticity (which is not to say that the distinction is universally false or always and everywhere a distortion). Rather, for the Frankfurt School, the task is to puncture reification, to unmask mystifying forms of ideology and the interests that they serve (which, again, is not to say that all ideology is necessarily a distortion. Were that the case, it would not be possible even in principle to assess the true function of

mystifications. There would be nothing to reveal behind the mask. But to the extent that the idea of truth is preserved in ideology critique, the hidden elements in any object of analysis – such as a curriculum, for instance – can be revealed for what they are). Following Marx' thesis 11 in his "Theses on Feuerbach" – "Philosophers have hitherto only interpreted the world in various ways; the point is to change it" (Marx 1975) – Max Horkheimer and the Frankfurt School understood the task of critical theory as at once explanatory, practical, and normative. This means that an adequate analysis must reveal the contradictions inherent in present social reality in such a way as to see what real possibility different actors have to change it, while at the same time providing an account of the criteria for distinguishing truth from falsity and practical possibility from idealistic utopianism (Benhabib 1992). Habermas, for instance, thinks that we can salvage the unfinished project of modernity or Enlightenment from the domination of instrumental-rationality by providing criteria for identifying and assessing claims within a conception of broader human interests: an emancipatory reason (Habermas 1971). Similarly, Giroux argues that a critical theory of pedagogy should not only analyze how educational institutions promote and sustain ideologies but also how these ideologies are in practice resisted, accepted, and negotiated by the actors involved (students and teachers, especially) in concrete situations; that is, in critical pedagogical theory, the analysis aims not only at explanation, but in identifying practicable goals and means for transformative action (Giroux 2001).

According to a more orthodox Marxist analysis of culture, capital always works to reproduce the ideological conditions necessary to reproduce itself and the social conditions that serve the interests of the elites. Among the essential features of this ideology is the general capitalization of modern social life. It achieves this through the illusion of transaction, of a neutral, transparent, equal, and free exchange, where in fact there abides a subterranean but specifiable relationship of dependency perpetuated by the constant renewal of the institutions and forms of the market (i.e., exchange value

is regarded as a neutral fact and not itself as "value laden"). In this respect, while education in reading and writing is surely emancipatory, the capacity for imagining another value system and the ability to see beyond one's own immediate situation are all the more so. Thus, consciousness raising is, for a critical theorist of education such as Paolo Freire, fundamental to the project of education. For Freire, theory cannot be separated from praxis and action, for which reason education must take the concrete lived situation of the learner as its starting point. To reproduce the hierarchical structure of society in which the teacher is the mouthpiece of established truth of which the student is passive recipient is to inculcate the values of unequal value in the youth (Freire 1973). In what Freire criticizes as the "banking" paradigm, to learn is to be managed, that is, to be trained to store a deposit of "learning" the value of which is decided once and for all as given without regard to its use for the learner or the conditions of his learning. In contrast, he proposes a method of teaching in which alphabetization, and language acquisition and development more generally, goes hand in hand with critical thinking, through active generation rather than passive consumption, where the concrete lived situation (say, the political and economic conditions that give rise to the slum) becomes the starting point for a discussion of the word and its constituent parts, which generate new words and thus the mastery of reading and writing. The decision to learn to read and write is born together with the decision to change one's life situation.

Inspired by the Frankfurt School, advocates of critical pedagogy are deeply influenced by the early Marx' analyses of alienated labor in which the laborer in modern capitalist society is not only alienated from the product of his work, but ultimately from himself. In critical theory of education, the analyses are broadened to include the labor of learning in the modern educational system of first-world capitalist society. Just as the means of production and the social relations in which they are embedded must be changed for the laborer to become free, the very character of educational institutions and their instruments are antithetical to genuine autonomy, on this analysis. Instead of reproducing the stratified social relations of

production and the values they embody, they ought to strive toward emancipatory or “empowerment” education. In this sense, they not only retain but also emphasize the Kantian element in critical theory, that is, the idea that the aim of critique is to examine the limits of the validity of a body of knowledge if it is to be established as genuine knowledge (which, in the case of critical theory, means knowledge that is of use to the knower). For critical theory, this involves the disestablishment of false, mystifying or repressive philosophical, social, and political assumptions. Kant’s critique of dogmatic metaphysics was connected to the enhancement of ethical autonomy as a cornerstone of pedagogics in the respect that he saw the cultivating of the capacity for self-liberation from arbitrary authority as one of the most important aims of education (Kant 2003). The connection between self-reflection and emancipation (from one’s own irrational self-limitation as well as that of external domination) as the central goals of education is also emphasized in critical theory, with the Marxian twist that the self to be reflected on and liberated is essentially social. Consciousness raising, as a desedimentation of layers of socialization, becomes nearly synonymous with education, since all empowerment (such as acquiring or enhancing literacy) is potentially a form of resistance.

Introduction

If there is one issue that has seen general consensus in the United States over the years, it is the idea that education is the path to ensuring individual advancement and overall human progress. How to ensure that education stays abreast of the passing times is, however, a much-debated, hard-fought ground. This entry approaches the central topic – cultural studies and education in the era of digital communication – in the hope of capturing the excitement of groundbreaking developments in educative practices, student engagement, educational policy, research, and practice in educational trends. In doing so, it focuses not merely on major shifts but also the nuances of a deeply contested ground.

Educational theorists have rightly pointed out: “We live in an extraordinary moment of socio-technical change. . . . The shifts we are experiencing today implicate our most fundamental relationships of representation and communication. . . .” (Cope et al. 2011, p. 91). In these dynamic times, what must be highlighted are moments and intersections that define the current conjuncture as communication and information technologies (C&ITs) transform the world and are well-poised to revolutionize educational theory, communication, and practice. Drawing upon Walter Benjamin’s proposal that “the way human perception is organized – the medium in which it occurs – is conditioned not only by nature but by history” (Benjamin 2008, p. 23), this entry focuses on contemporary educational practices as they evolve from an inexorable blending of digital communication in all areas of human life on one hand and developments in educational policy and burgeoning educational technology on the other. Specifically, the spotlight is on key stakeholders within the field of *education in the digital era*: students, educators, practitioners, policymakers, and parents. Taking from Bourdieu’s (1993, pp. 162–164) description of the “field” as a separate social universe having its own laws of functioning, independent of those of politics and the economy, here the reading of “field” is not as an area entirely independent of the historical conditions of its production but rather that which refracts every external determination and retranslates it according to its own specific

logic. The field particularly referred to here involves the culture of digital educational practices in the twenty-first century. While everything from educational technologies and instructional methods to assessment software or curriculum innovations are in the process of profound revision, the focus here is on emerging intersections between educational policymaking, practices, and innovations in educational technology.

In the United States, the national push for Common Core State Standards emphasizes the mastery of certain proficiencies “essential for college and career readiness in a twenty-first century, globally competitive society.” This means that the digital age and attendant global connectivities have driven educational agenda with an accelerated speed. Such push is manifested in the consideration of media technologies within the Common Core in which they reason, “students need the ability to gather, comprehend, evaluate, synthesize, and report on information and ideas, to conduct original research in order to answer questions or solve problems, and to analyze and create a high volume and extensive range of print and nonprint texts in media forms old and new” (English Language Arts Standards, Common Core State Standards Initiative, 2010). While media and technology have never been out of the spotlight of education and cultural studies, being written in a nation’s educational standards calls for a rethinking of the nexus between educational policymaking, a technology-enabled competitive marketplace, and “market-style institutional arrangements” (Lubienski 2005, p. 467).

It is undeniable that rapid changes in the field of higher education crucially affect K-12 education and what it is expected to yield toward college populations. Therefore, irrespective of the levels, for cultural studies, it is increasingly relevant to review how paradigmatic revisions in overall educational systems come to bear upon the most important stakeholder – the student, by nature a digital native and an expert in computer-mediated communication (CMC). The synergy between the student and the environment, even as he/she is placed within an increasingly demanding, unconventional, yet promising educational milieu, gains centrality. The critical question on what is the status of the digital in educational reform discourse

potentially sharpens attention on the conjunctural moment in which young people seem to have seized hold of the affordances of digital technologies and the establishment curriculum actors are somehow traveling behind.

Policy, Educators, and the Student

What is the role of policymaking and how does it address the needs of the hour especially from the perspective of the student? How does it reconfigure attendant power relationships? These pressing questions have been at the forefront of debates in curriculum studies and in the broader field of education. Notably, the power constructs that regulate social and cultural contexts make their way into student lives in the form of curriculum, classrooms, and school practices (Giroux and Aronowitz 1993). While the issue of K-12 curriculum, education standards, and measures to strengthen primary and secondary education in the United States has been in wide discussion, proliferating the media over several years, the common thread in these debates has often placed the matter within the domain of politicians and K-12 educators and also been affected by a disconnect between higher education researchers and school teachers (Hess 2015). However, the situation is not only “ripe for change,” but “in tandem with the rapid evolution of higher education, primary and secondary education are undergoing a transformation of their own” (Hess et al. 2015, p. 241). Drawing on Foucault, Popkewitz and Brennan argued that it is essential to consider how power/knowledge dynamics inform educational spaces because “knowledge (defined by power relationships) has a material element in social life” (1997, p. 288). This is no different in the digital educational spaces.

Casting a quick glance at the historical context, the Common Core, finalized and released in June 2010 and subsequently adopted by 43 States in the United States, had the objective of enabling “students to be ready to succeed in credit bearing, college entry courses and in workforce training programs” (Common Core State Standards Initiative, 2006, as cited in Taft, in Hess et al. 2015, p. 245). Building upon recommendations from education policies

such as No Child Left Behind and Race to the Top, the Common Core's mandate was reinforced by an educational environment where testing and standardization have been encouraged and rewarded (Bills 2004). The introduction of the Common Core is by no means an uncontested or insignificant development for the US educational system. Public opinion has been divided, with strong criticism coming from researchers, teachers, and school districts, particularly about the amount of time spent in testing, the need for instructors to teach to the test as opposed to enhancing learning, as well as the lack of evidence to show connections between testing and learning. Educators are pointing to the fact that it seems to be built around the idea of uniformity, whereas to be effective, the future of education should be in promoting diversity in learning environments. More to the point, the speaking and listening components introduced in the English Language Arts Standards in response to "greater demands for knowledge workers with highly-developed communication skills" (Bodary, in Hess et al. 2015, p. 246) need to be problematized. While policymakers acknowledge that this does not imply simple public-speaking skills but must aim to incorporate strategic use of digital media technologies, researchers emphasize on the need for "application of technology and new media informed by communication research" (Beebe, in Hess et al. 2015, p. 254) in effecting outcome-based educational standards.

For cultural studies, this is an active intersection of policy and student experience. For the new-generation student, mobile phones, tablets, and handheld computing devices are household terms. Handhelds are seen not so much as technology but as extensions of their own faculties. They have developed innate abilities to live their lives at their fingertips and on the screens of their computers, laptops, and, even more often, their mobile handhelds and tablets, such as iPads. Entire conversations are held through various forms of text messaging, communities and friendships are built and maintained over Facebook, and their life possessions – now more often digital than material – are archived on media spaces like YouTube and Facebook. How will this recent emphasis on speaking and listening reconfigure the power dynamics within the learning

environment, especially for the student already possessing a high degree of digital literacy and more geared to computer-mediated communication, is a question that must be engaged in the near future. The student's agency and also their increasingly proactive engagement with digital learning environment form a substantial part of such consideration. After all, Paul Willis has brilliantly argued in his essay "Foot Soldiers of Modernity" (in McCarthy et al. 2005, p. 468) that as policy planners become fixated on the internal logics of their "top-down" initiatives, they fail to dwell on the unintended consequences of their policies. Thus, the school often becomes the principal site for playing out various social contradictions and tensions and students find themselves at the frontline of these conflicts, often called upon to challenge not only its "underlying individualistic and meritocratic ideologies" but also the practical inability of the school to connect the young to meaningful prospects in the job world. Policies are meaningful when they incorporate provisions not only for incorporating proficiencies already maturing in its stakeholders but also in being open to innovations arriving from an increasingly diverse field of technology-mediated learning (TML). The next section attends to several such innovative strides that are revolutionizing online learning.

Theory, Technology, and Practice

Earlier research on educational technologies had suggested that they were deployed in "support of" face-to-face teaching, distance learning, and self-learning (Chaves 1999). Contemporary flows indicate that TML has undergone a sea change with digital technologies and platforms often operating "in the place of" conventional classroom teaching and learning. We see this in experimental environments of massive open online courses (MOOCs) offered by big universities, social networking sites for education, online lectures and video learning (TED, YT EDU, @GoogleTalks, Reddit lectures), open education resources (Open Textbooks, Scribd, Creative Commons Education), and innumerable other online learning options. Scholars rightly

noted that educational technologies had earlier implied more focus on stand-alone techniques, systems, and devices (Cope et al. 2011; Bruce 1999). Current implications of the term have shifted considerably to accommodate new communication and information technologies (C&ITs) being deployed to optimize strategies of outcome-based education. Research that predicted the “*mediational* function” of new media where new technologies provide “affordances of learning” and “*mediate* between students, between student and teacher, and among task, resources, situation, and students” (Bruce 1999) has found its mark when one considers that conventional models of education and tutoring are not merely being challenged but also replaced by online learning practices. According to educational policy theorists, “evolving technologies, applied to the discursive and social relations of new writing spaces on the Internet, provide us for the first time with a paradigm-changing opportunity” (Cope et al. 2011, p. 81) in providing tools to transform assessment and thereon to transform learning itself.

On the other hand, educational technology practitioners from ventures like EdSurge and Project Tomorrow are insistent that innovative educational technologies and business models from the Silicon Valley are the trajectories to the future of the US educational system. That innovation and entrepreneurship is steadily and not so slowly taking the field by storm is not to be debated. The Speak Up Survey (2013) of 400,000 respondents from 9000 schools in 2700 districts across the country showed the magnitude of this approaching transformation (Riedel, 2015). A staggering 89% of high school students and 50% of 3rd to 5th grade students were shown to have access to Internet-connected smartphones, with comparable degrees of access to tablets and laptops. Sixty-four percent of the respondents identified 3-G- or 4-G-enabled devices as their primary means of connecting to the Internet. Not all of them are playing games online, when we note that one third of the students are accessing online videos to get help with their homework. It is not surprising, since 46% of the teachers use videos in their classroom teaching and 23% of the students access videos uploaded by their teachers.

The versatility of such technology usage in education is in the fact that majority of the students surveyed leveraged mobile devices to not merely transform their learning processes but integrate anytime research work, peer collaboration, and educational games into leisure activities, efficiency measures, and daily tasks – establishing C&ITs as integral parts of their lives and culture. Such rising trends as use of videos and online learning networks are being called the “Khan Academy effect,” after a controversial digital learning organization called Khan Academy which hosts a series of videos offering step-by-step instructions on how to solve Math problems. While Khan Academy’s popularity is hard to understand considering charges of low-resolution videos, erroneous presentations, and lack of pedagogical intentionality, it still remains important and impactful because its informal online learning platforms represent a shift in the culture of the educational environment with a DIY attitude becoming the norm. Khan Academy’s webpage proudly displays the message: “Watch. Practice. Learn almost anything – for free” (Bingham 2011). Research shows that the Khan Academy had 10 million unique users in 2014, of which 65% were from the United States alone (Research on use of Khan Academy in Schools, 2014).

From the C&IT practitioner’s perspective, the most interesting problem to solve in strengthening education is not actually in using technology per se to improve teaching. Instead, it is in finding a way to create better incentives and competition so that better ideas and approaches win out over time. This is how technology improves – there is constant competition with strong incentives for individuals or companies to come up with new ideas to improve on the status quo (and typically to make a profit if successful). Extensive research on market-style mechanisms and competition-based educational reforms, however, points to different dynamics in the field of education. Scholars argue that educational organizations, in order to succeed in the marketplace, often respond to competitive pressures by developing marketing and promotional strategies “having to do with symbolic management of a school’s image rather than substantive changes in its educational processes” (Lubienski 2005, p. 465).

How the digital era will reconfigure educational practices, considering the fact that TML services like *Instapundit* or *Mathalicious* have become remarkably prolific within education sector, still remains to be seen. However, in noting the advances by MOOC networks like *Coursera*, *MIT OpenCourseWare*, and *Udacity*, many of them geared as substitutes to classroom learning, major upcoming shifts in educational culture are inevitable. While there is not much doubt about the fact that this already marks a historical juncture “with momentous changes in the availability of what can be easily accessed and learned online,” scholars also point to the debates on the evolving role of teachers (Bingham 2011). The next section looks at the changing roles of educators and also how teachers and parents are assuming positions within the drastically changing educational environment.

Parental Academic Support and the Teacher

When knowledge is easily and quickly accessible by all people, what, then, is the role of the educator? With the easy accessibility of information on the Internet, discussions have emerged on the need for teachers’ “intensified progressivism.” The trend is toward a demand for the teacher to be more knowledgeable than ever before by staying abreast with advances through intense engagement with technology. In this regard, educational theorists have argued that “relationality” is at the core of the educational endeavor and “education is primarily about human beings who need to meet together as a group of people if learning is to take place” (Bingham 2011).

Hence, social relations between parents and teachers evolve as another significant area. Education is considered a “public good” in the United States, as in most developed countries, and this sector is heavily regulated. It is also extremely fragmented. Schools operate under strict oversight by local communities and various levels of government. An important component within this oversight is the parent’s involvement in academic support and parent-teacher communication. Digital communication and C&ITs like smartphones and social networking systems are shaping these social relations.

While extensive scholarship is emerging using the media richness theory (MRT) to test patterns in this respect, here, of interest is a 2015 study that reports that in contrary to the basic thesis of MRT, parents increasingly prefer lean media communication like e-mails and texting over richer media modes like FTF and phone or more advanced digital platforms like Skype or FaceTime. However, it identifies the smartphone as a key component of higher level of parental academic support (PAS) and connection between these two stakeholders (Thompson et al. 2015). With two thirds of consumers using smartphones within the United States, this mobile device has taken PAS to a new level as parents rely heavily on e-mails and text messages to keep abreast. This is of great value, considering that the ease of usage also boosts frequency of communication. Even though teacher’s involvement, self-disclosure, and engagement in Facebook have showed positive influence in student motivation and learning, as well as teacher-student relations, it is the handheld mobile that creates a surge in PAS, a longtime constant in student welfare. Parents’ increased entry into the social networking system also bodes well for parent-teacher communication and, consequently, parental academic support.

Conclusion

One of the celebrated notions of technology in cultural studies from Raymond Williams (2003) is that new technology is not merely an outgrowth of social needs but it was also foreseen by people through lived experiences. If this is true, then certain important consequences follow from this view. It follows, for instance, that cultural studies of education in the digital age should not only focus on new technologies themselves (e.g., C&ITs, MOOCs) but also pay close attention to “players” from where the clues about the future development in educative practices can be furnished. For this reason, this entry looked into the lived experiences of key stakeholders. Rejecting technological determinism that C&ITs alone have made a new generation of students, we highlighted the power relations embedded in the processes of policymaking, proliferation of new

educational platforms, marketing promotion, and parental academic support among different actors. We demonstrated that the reconstruction of the power relations is the product of the educational space in the digital age on the one hand and producing new meanings for the reconfiguration of education on the other.

Cultural Studies and New Student Resistance

Cristian Cabalin

Institute of Communication and Image/Center for Advanced Research in Education, University of Chile, Santiago, Chile

Synonyms

Cultural politics of education; Higher student movements; Subcultures; Youth movements; Education and youth protests; Media and youth movements

Introduction

Youth and resistance are two concepts closely linked to the development of Cultural Studies. Both contain the elements of topics of interest for Cultural Studies: power, historicity, categorization, and social structure. Youth and resistance seem to refer directly to the claims of social change, to those practices that subvert the inherited order and challenge the traditional patterns of the order of society. To amalgamate these concepts, the notion of subcultures has been widely employed. In fact, one of the primary texts on the subject and one of the most important works about youth in the tradition of Cultural Studies associated youth and resistance with a configuration of differentiated structures within broader cultural networks. This is how “subculture” was defined in *Resistance Through Rituals: Youth Subcultures in Post-war Britain* (Hall and Jefferson 1993), which was the study done by the first generation of graduates from the Centre for Contemporary Cultural Studies of Birmingham, originally published in 1975 with the goal to explain the phenomenon of “youth culture” in Britain after the war. Dick Hebdige followed this line of research with *Subculture: The Meaning of Style* (1979), a key text in the study of youth and subculture. From these works, youth have been of particular interest to those who use Cultural Studies as the main

reference in the fields of communication, education, sociology, anthropology, history, and literature.

Youth is a conceptual category that allows for the organization of a social group within a given set of features. Thus, youths, when using a more conservative lens, would primarily be seen as incomplete adults, prone to disorder and to disrupting the harmony of society. Therefore, the early works that considered this subject of study were especially dedicated to juvenile delinquency (Baker 2012). In a more romantic vision of youth, on the other hand, youth would be the only possibility of overcoming the mistakes of the present and leading society towards a more prosperous and just horizon. Cultural Studies subverts both viewpoints and stresses the analysis of the categories of youth, which cannot be conceived as a homogeneous group or even as a single age group. Youth as a social category is influenced by race, class, and power, as well as in other ways, as we have been taught in Cultural Studies.

Today in education, this complex framework of analysis proposed by Cultural Studies might be usefully applied in examining the current younger generation that is attending higher education in such large numbers in many countries. To reflect on this point, this entry will explore the case of the Chilean student movement of 2011, which has been one of the most important expressions of youth resistance in the recent history of Chile and that inspired other social movements in different countries. As such an educational-cultural approach will be used to analyze the Chilean student movement.

Youth and Educational Credentials

Chile has a massive higher education system where more than 30% of the population who are of age attend a college or career school. In 1986, the higher education system had 240,000 students, where now 1,200,000 students are enrolled. It is also important to note that 7 out of 10 youths are the first generation of his/her family to attend university. These two facts are key to understanding the student movement: never before in the history of Chile have youth been so educated with higher academic credentials. However, this

massive result, among others, of the neoliberal reforms of the Pinochet dictatorship in the 1980s does not necessarily imply that the higher education system is working effectively in terms of social equality. The fact that 70% of youths are the first generation to go to college does not mean that there has been a rearrangement in the social structure in Chile; on the contrary, scarce upward social mobility and the educational system reproduce inherited privileges.

Chilean students took to the streets en masse for 7 months in 2011, because the neoliberal promise of social mobility has been a failure in the country. Here, Cultural Studies, as an area of research, is relevant because if we apply the historical thinking that its exponents proposed in *Resistance through Rituals*, it is possible to note that these changes to the massiveness of the educational system have produced social breakdowns in all countries with the same uneasiness. In the 1950s and 1960s, in Great Britain, the meritocratic ideology, as it is illustrated in *Resistance through Rituals*, led us to believe that education would be the springboard for an extended number of children of the working class to jump into the ruling classes. The result, rather, was a devaluation of academic credentials and the generation of a uniform middle class with limited mobility.

This meritocratic ideology has also been a dominant discourse in countries such as Chile, which is considered, from a colonial perspective, as “developing.” Education has been the bet for many youth and their families. Students take out expensive loans to pay for college and have hope for a better future than their parents had; but for a third of them, this step up to education is not profitable and students end up unemployed, or working on something that they did not study, and completely indebted.

This debt and frustration is accompanied by underemployment or subpar work opportunities. Underemployment is another consequence of the higher education system, which has promoted a direct relationship between jobs and academic credentials (Cunningham 2015) and has simply turned many students into the “enlightened unemployed.” Faced with this reality, Chilean students rebelled in 2011, demonstrating that youth resistance is

possible if innovative strategies are combined with a wide range of political and educational resources.

Youth as Media Savvy Political Actors: A Case of Resistance

One of the characteristics of students mobilized in 2011 was its close relationship with the new communication platforms. Facebook, Twitter, and YouTube were the main tools for dissemination and massification of messages to students. Social movements require strong communication tools because the traditional media tend to focus on the status quo and generally criminalize resistance movements. In Chile, during the transition from dictatorship to democracy in the 1990s, the student movements failed to break through the information barrier. However, in 2011 and after a long process of accumulation of political experiences that began with the demonstrations of high school students in 2001 and 2006, students became protagonists in the debate about education in Chile.

Cultural Studies has rightly sought to understand the relationship that people establish with the media from a sociocultural point of view and not merely a cognitive one (effects of the media on the mind of the subject). If we use this sociocultural point of view to look at the 2011 Chilean student movement, it is possible to notice the importance of the media in its success. According to various surveys, the students got 80% support of the population who agreed with their principle demands (free education and an end to profit in education) (Bellei et al. 2014). Moreover, they changed the agenda of educational policies, and their leaders were widely known public figures that succeeded in attracting the attention of thousands of citizens in each march or street demonstration. This was possible, among other reasons, due to the systematic presence in traditional media (radio, newspapers, and television) and the intensive use of online social networks.

The first march of students in April of 2011 brought together more than 10,000 people, but the following street demonstrations between May and November always exceeded 80,000 people, with maximum number of 200,000 people in some

marches in Santiago during the Chilean winter (June-July-August, 2011). These adherents were told of the movement's activities mainly through television and Facebook. On both platforms, students displayed their communicative actions. Their leaders attended all news and political programs on Chilean television; on morning and entertainment programs, these leaders spoke of the students' demands and video digital social networks called for protests and student proposals were broadcast.

The students considered communication as an essential dimension of their movement and the media as platforms for common sense debates. The greatest triumph of the students is seen in the changes in the subjectivity of Chileans. In a recent report of the United Nations Program for Development (UNDP), it is concluded that since 2011, Chile is undergoing a process of politicization (PNUD 2015). The report indicated that a constant tension exists between the real, the possible and the legitimate in Chilean society, where people are much more critical of the institutions and traditional forms of political representation. In addition, during this process of politicization, youth resistance movements have played a key role, because they challenge the elite and, in turn, help the creation of new frameworks for interpreting the reality of people.

The Chilean student movement of 2011 conjugated massive criticism of the neoliberal education system and against the technocratic design of education policies. Education became a field of ideological dispute, as never known before in the country.

To produce this result, students used different communication platforms with discourses focused on social justice, equality, and education as a social right. They developed strong political content and effectively communicated a message containing the main discomforts of students: high debt, low quality of education, precarious jobs after graduation, and irregular business aspects in education. This message was sophisticatedly prepared and disseminated in all possible news programs and in the street.

For the success of the movement, the students applied the knowledge acquired in their own way through the higher education system: economics students filled the documents of the student organization with facts and figures to argue with

evidence against the government's proposals, medical students and nursing tended to the wounded during street protests, engineering students developed smartphone applications in order to inform the participants of the march as well as the itinerary, and communication students produced television programs transmitted by the Internet to disseminate the students' message.

The latter two cases are the most relevant for Cultural Studies in education, because both combine a reflection on technology and society, as described in the classic *Television: Technology and Cultural Form* (1974) by Raymond Williams, one of the great intellectuals of British Cultural Studies. Engineering students developed apps to inform other students about marches, and communication students conducted programs via streaming to spread the message of the movement, combining the high knowledge in both disciplines, but emphasizing, above all, the political use of knowledge and technology. Students used their cognitive skills formed in internships in college to support the movement, thus subverting the traditional notion of higher education as a simple step into the labor market. Students realized that their skills were not functional to the labor market but were essential to establish themselves as political actors in society.

This notion of the political actor alters the conventional way of conceiving a student in a neoliberal education system, which considers him/her as a simple consumer of an educational service. The student as a political actor demands a higher requirement: his/her understanding as a subject of rights. This is a radical change in the governance of institutions. In Chile, governance in the public sphere has been given to a group of professionals who were deemed "ideologically neutral" and "politically disinterested" for several decades, who were "serving their country" with the expertise they acquired in the best universities around the world. In a neoliberal context, the State does not disappear, but loses ground in this area to a new community of "intellectuals" who acquire sufficient power to determine educational policies. The 2011, student movement seriously challenged this hegemonic technique.

Student marches demonstrated the strength of student demands and their ability to articulate a

discourse on education that has permeated the cultural and political structures. This is a new generation of youth with an enormous capacity to convert their justified complaints against the educational system in a political way of transformation. The movement shook the prevailing order and system of governance within these educational institutions. The demand for more democracy was not only within the political system but also for discussions within communities. Verticality in decision-making is no longer possible in the current political climate. In Chile, universities are exposed to more critical and demanding students, who want to participate and who do not accept a secondary role so easily.

Thus it is possible to argue that since 2011, the Chilean educational field has been repoliticized by political actors and not by policy specialists. This is not just a semantic change; it is also a new approach to educational problems. For a long time, experts, who were deemed as such by the elite and by the media, were the protagonists of educational policies. Students have recovered this place for the educational community, expanding the areas of action in education. Thus, they materialize their resistance to neoliberal policies implemented in Chilean education since the market reforms of the dictatorship of Augusto Pinochet (1973–1990). In fact, one of the leaders of the Chilean movement points out: "Our action was intended to realize that the collusion between politics and money was the structural axis and stabilizer of neoliberal education, not an accident" (Figueroa 2013, p. 69).

The Chilean student movement of 2011, in this way, constituted a paradigmatic case study of youth resistance against neoliberal hegemony. To understand resistance, from a Cultural Studies point of view, Barker's (2012) definition of resistance states that resistance is a "category of normative judgment acts. Resistance issues from relationship of power and subordination in the forms of challenges to and negotiations of the ascendant order. Resistance is relational and conjunctural" (p. 509). To reach this definition of resistance, Barker based this idea on the reading of Stuart Hall and Tony Jefferson's edited volume, *Resistance through Rituals*, which conceives of resistance "as challenges to and negotiations of dominant order which could not be assimilated to the traditional categories of

revolutionary class struggle” (Hall 1996, p. 294, cited in Baker 2012, p. 455).

If the youth resistance has its peculiarities and is temporary, how is it possible to understand the student movement? One possible answer lies in the work of Gill and DeFronzo (2009) who point out that a student movement can be considered as:

a relatively organized effort on the part of a large number of students to either bring about or prevent change in any one of the following: policies, institutional personnel, social structure (institutions), or cultural aspects of society involving either institutionalized or non-institutionalized collective actions or both simultaneously. (p. 208)

These authors establish four types of student movements, and the combination of political and sociocultural factors determine the type of movement: reformist, radical identity, structural revolutionary, and social revolutionary (Gill and DeFronzo 2009, pp. 209–214). It could be hypothesized that the 2011 Chilean student movement evolved from a reformist movement to a social revolutionary one, because in the end the students proposed to change the educational system, political representation, and culture.

Because resistance is relational, it is necessary to frame the Chilean student movement within the conditions that allowed for its development. At this point, four dimensions can be identified that explain the circumstances that made the resistance possible: (1) the students had cause for complaint (grievance) due to the advancement of educational coverage, but also in turn the extent of educational inequality, high indebtedness, and future unemployment. In this assumption, the movements would be an unintended consequence of neoliberalism applied in Chile; (2) they were able to successfully communicate and frame (cultural framing) their demands to connect with people, mobilize supporters, and intervene in the political system; (3) they took advantage of their political opportunities during the presidential periods of Michelle Bachelet (2006–2010) – for her promise of a citizen government – and of Sebastián Piñera (2010–2014) following his announcement of a higher education reform; and (4) the disposition and the intensive use of intellectual, human, technological, and political

resources in innovative ways (Bellei et al. 2014). This is, undoubtedly, the most educated and best prepared generation in the history of Chile.

Conclusion: “The Generation Without Fear”

This new and active Chilean generation is not marked by the trauma of the generation that suffered and fought the dictatorship of Augusto Pinochet. It is a “generation without fear” that has altered the educational field to a new level of relations. Another leader of the movement, Giorgio Jackson (2013) sums it up by saying: “We are a generation that was not born under the trauma of dictatorship, a generation with less fear, raised in the post-dictatorship” (p. 110). This new generation, as expressed in the student movement of 2011, has extended the limits of Chilean democracy and shaken the foundations of the Chilean education system. These students have also become actors who define educational policies. In addition, the students have allowed for the expansion of the understanding of social movements and the value of new technologies for citizen participation. For a long time, in Chile, youth were seen as apathetic and disinterested. But this point of view only replicated the classic framework of citizens, who were reduced to participating politically only through voting in the regular elections of the political system.

In 2011, university students took to the streets to counter the current dynamics and contradictions of the Chilean neoliberal system. Therefore, we cannot describe this movement as a “typical” expression of youthful rebellion. On the contrary, this new generation of mobilized students demonstrated a kind of political astuteness and level of investment in structural change that we have not seen in the depiction of youth resistance in the British Cultural Studies tradition, where youth were presented rejecting adult authority more than calling for fundamental social change. In so doing, the 2011 Chilean student movement has effectively contributed to an expanded conversation on the urgent topic of youth and resistance in the Cultural Studies in education.

Cultural Studies and Public Pedagogy

Henry A. Giroux

McMaster University, Hamilton, Ontario, Canada

Introduction

My own interest in cultural studies emerges out of an ongoing project that attempts to theorize the regulatory and emancipatory relationship among culture, power, and politics as expressed through the dynamics of what I call public pedagogy, particularly as the latter is played out around the construction of youth within the broader terrain of schooling and popular culture. I have also been particularly concerned with challenging conservative, liberal, and left approaches that both abstract culture from the dynamics of power and politics and dismiss educators who engage pedagogy as a moral and political practice rather than as a rigid methodology. In the latter case, the conservative

script is a familiar one, but it has taken on a new urgency given the current backlash against women, urban youth, minorities of color, progressive academics, and the underlying fabric of the welfare State itself. Within this discourse, cultural politics is dismissed as a corrupting influence on the universal claims of truth, beauty, and reason. Even more surprising is the rejection of cultural politics shared by a growing number of progressives who narrowly define politics and pedagogy within a dichotomy that pits the alleged “real” material issues of class and labor against a fragmenting and marginalizing concern with the politics of culture, textuality, and difference. Caught between the modalities of a timeless universal aesthetic or a narrowly defined politics, culture in both instances is removed from power and viewed as either untainted by politics or simply a weak or secondary version of politics. Lost here is the attempt to develop a notion of culture that explores how learning is linked to social change, how authority makes it difficult for subaltern groups to speak in an way that carries any legitimacy, or how the pedagogical struggle over identities, meaning, affect, values, and desires takes place across a spectrum of public spheres in society.

In opposition to these positions, I think it is imperative that critical educators both recover and rethink the ways in which culture is related to power and how and where it functions both symbolically and institutionally as an educational, political, and economic force. Culture is constitutive rather than reflexive. That is, it not only reflects larger forces, it also shapes them. It is the ground of both contestation and accommodation; moreover, it is the terrain where young people and others imagine their relationship to the world; As Stuart Hall points out, “culture is the terrain where representations organize regulate and give meaning to social practices through the distribution of symbolic and material resources between different groups.” Culture provides the conditions for putting subject positions and identities in place, and it has become a major force for global historical changes. Moreover, it is increasingly characterized by the rise of institutions and technologies which are transforming the traditional spheres of the economy, industry, society, and everyday life. Culture

now plays a central role in producing narratives, metaphors, and images that exercise a powerful pedagogical force over how people think of themselves and their relationship to others.

Cultural Studies and Public Pedagogy

I want to argue that central to any viable notion of cultural studies is the assumption that culture and power must be organized through an understanding of how the political becomes pedagogical; that is, how the very processes of learning constitute the political mechanisms through which identities are shaped, desires mobilized, and experiences take on form and meaning. Pedagogy in this instance is not only central to cultural studies and cultural politics, it also can no longer be confined to the site of schooling, which as Raymond Williams reminds us signals how youth are constructed as subjects and subject to relations of power within and across a variety of public spaces. With this said, I want to comment on some very schematic and incomplete elements of cultural studies that I think are useful for thinking about the interface of some of the most insightful work being done in cultural studies and critical pedagogy.

First, in the face of contemporary forms of political and epistemological relativism, cultural studies makes a claim through an appeal to highly disciplined, theoretical work to find better forms of knowledge and authority in order to engage the problem as Stuart Hall puts it of addressing and understanding “what keeps making the lives we live and the societies we live in profoundly and deeply antihumane.” In this instance, cultural studies links its different projects with ethical and political referents that offer the possibility for defining and providing the institutional space and practice for educating teachers, students, and others to play a vital role in renewing civic life, redefining their role as public intellectuals, and addressing through their work some of the most urgent and pressing social problems facing us at the present time. Former CUNY chancellor Joe Murphy has captured the spirit of what it means for educators to address such a project. He argues that educators should “give students [the critical]

sensibility to understand economic, political, and historical forces so they’re not just victims of these forces but can act on them with effect. Giving [students, especially the poor] this power is a threatening idea to many. But it is essential to the health of a democratic society.”

Second, cultural studies is radically contextual in that the very questions that it ask change in every context. Pedagogy in this instance is always a response to particular contexts, questions, and social relations and its practices are judged in part by their ability to provide a better understanding of how power works in and through such contexts while simultaneously opening up imagined possibilities for changing them. Larry Grossberg puts it well in arguing that cultural studies must be grounded in an act of doing, what critical theorist Doug Kellner has aptly called “Doing Cultural Studies” which in this case means intervening into contexts and power in order to enable people to act more strategically in ways that change their context for the better. For educators, this suggests that pedagogy is not a priori set of methods that simply needs to be uncovered and then applied regardless of the contexts in which one teaches but is the outcome of numerous struggles between different groups over how contexts are made and unmade, often within unequal relations of power. In short, the historical, cultural, social, and economic forces at work in defining particular contexts will offer the limits and possibilities for developing the pedagogical strategies we undertake in schools and other cultural sites.

The notion that pedagogy is always contextual also suggests linking the curriculums we teach to the experiences that students bring to their encounter with schools and their institutionally legitimated knowledge and social relations. One implication for such work is that future and existing teachers be educated about the viability of developing context-dependent learning that takes account of student experiences and their relationships to popular culture and the terrain of pleasure, including those cultural industries that are often dismissed as producing mere entertainment. Despite the growing diversity of students in both public schools and higher education, there are few examples of curriculum sensitivity to the multiplicity of economic,

social, and cultural factors bearing on students' educational lives. Even where there is a proliferation of programs such as ethnic and black studies in higher education, these are often marginalized in small programs far removed from the courses organized around history, science, and the humanities majors. Cultural studies at least provides the theoretical tools for allowing teachers and other cultural workers to recognize the cultural resources that students bring to school and other educational sites and the need to honor them by both affirming and engaging them critically as forms of knowledge crucial to the production of their sense of place, history, and how they envision their relationship to others. Equally important, the knowledge produced by students offers educators an opportunity to learn from young people and to incorporate such knowledge as an integral part of their own teaching.

Third, the cultural studies emphasis on interdisciplinarity is important because it provides a rationale for challenging and questioning not only how knowledge has been historically produced, hierarchized, and used to sanction particular form of authority and exclusions but also because it operates at the frontiers of knowledge and prompts teachers and students to raise new questions and models of analysis outside of the already officially sanctioned boundaries of knowledge, while at the same time activating student involvement in gaining ownership over different aspects of their learning. The point here is that educators question and work across academic disciplines but at the same time they value disciplinary work rather than simply dismiss it. In part, this suggests reformulating the value and implications of established disciplines and those areas of study that constitute mass culture, popular culture, youth culture, and other aspects of student knowledge and the contested terrain of common sense. This is not a matter of abandoning high culture or simply substituting it for popular culture. It is rather an attempt to refigure the boundaries of what constitutes culture and really useful knowledge in order to study it in new and critical ways.

Fourth, in a somewhat related way, the emphasis on the part of cultural studies theorists to study the full range of cultural practices as they circulate throughout society opens the possibility for

understanding the educational force of a whole range of new cultural forms within media culture that have become the primary educational forces in advanced industrial societies. Educators must become more reflective about engaging and studying the production, reception, and situated use of varied popular texts, and how they structure social relations, values, particular notions of community, the future, and diverse definitions of the self. Texts in this sense do not merely refer to the culture of print or the technology of the book but to all those audio, visual, and electronically mediated forms of knowledge that have prompted a radical shift in the construction of knowledge and the ways in which knowledge is produced, received, and consumed. Recently, my own work has focused on the ways in which the Disney's corporate culture, particularly through its animated films, radio programs, theme parks, and Hollywood blockbusters, functions as a expansive teaching machine in which it appropriates media and popular culture to rewrite public memory and offer students an almost entirely privatized and commercialized notion of citizenship. One could equally imagine using a popular magazine such as National Geographic to study the history of colonial representations in the popular imagination.

As Benjamin Barber noted in a recent issue of *The Nation*, "It is time to recognize that the true tutors of our children are not [only] the schoolteachers or university professors but [also] film makers, advertising executives and pop culture purveyors. Disney does more than Duke (University), Spielberg outweighs Stanford, (and) MTV trumps MIT." Barber is partly correct in noting that contemporary youth do not simply rely on the technology and culture of the book to construct and affirm their identities; instead, they are faced with the task of finding their way through a decentered cultural landscape no longer caught in the grip of a technology of print or closed narrative structures. I do not believe that educators and other cultural workers can critically understand and engage the shifting attitudes, representations, and desires of this new generation of youth within the dominant disciplinary configurations of knowledge and practice. A more critical and oppositional

pedagogical practice must be aimed at providing the conditions for young people and adults to engage in popular media and mass culture seriously as objects of social analysis and to learn how to read them critically through specific strategies of understanding, engagement, and transformation. At stake here is a view of literacy that is multiple and plural rather than singular and fixed. The modernist emphasis on literacy must be reconfigured in order for students to learn multiple literacies rooted in a mastery of diverse symbolic domains. At the same time, it is not enough to educate students to be simply critical readers across a variety of cultural domains, they must also become cultural producers. That is, they must learn how to utilize the new electronic technologies and how to think about the dynamics of cultural power and how it works on and through them so that they can learn how to build alternative cultural spheres in which such power is shared and is used to promote non-commodified values rather than simply mimic corporate culture and its underlying transactions.

Fifth, cultural studies also rightly argues for the importance of analyzing history not as a totalizing narrative unproblematically linked to progress but as a series of ruptures and displacements. History in this sense becomes decentered, more complex, and diffuse. Rather than taking up history within the confines of a rigid and narrowly defined Western tradition, teachers can name and address the multiple traditions and narratives that constitute the complex and multilayered constructions, deployments, and uses of national and global identities and public memories. The pedagogical benefit of such an approach is that it makes available to students those narratives, local histories, and subjugated memories that have been excluded and marginalized in dominant renditions of history. Through the lens of cultural studies, history can be read from a transnational and intercultural perspective. In part, history becomes a critical reading focused on the local and global relations that the United States has constructed over time with other countries. Historical learning in this sense is not about constructing a linear narrative but about blasting history open, rupturing its silences, highlighting its detours, and organizing

its limits within an open and honest concern with human suffering, values, and the legacy of the often unrepresentable or misrepresented.

History is not an artifact but a struggle over the relationship between representation and agency. James Clifford is insightful in arguing that history should “force a sense of location on those who engage with it.” In other words, history is not merely about looking at facts, dates, and events. It is also about critically examining one’s own historical location amid relations of power, privilege, or subordination. Similarly, cultural studies strongly supports the notion that the work of theory, research, and practice must, in part, be approached through historical undertakings and struggles around nationhood, ethnicity, race, gender, class, youth cultures, and other contestations over culture and politics.

Sixth, the issue of pedagogy is increasingly becoming one of the defining principles of cultural studies. Pedagogy represents forms of cultural production and struggle implicated in and critically attentive to how power and meaning are employed in the construction and organization of knowledge, desires, values, and identities. Pedagogy in this sense is not reduced to the mastering of skills or techniques. Rather, it is defined as a cultural practice that must be accountable ethically and politically for the stories it produces, the claims it makes on social memories, and the images of the future it deems legitimate. As both an object of critique and a method of cultural production, critical pedagogical practices should refuse to hide behind claims of objectivity and must work, in part, to link theory and practice in the service of expanding the possibilities for democratic life. In the broadest sense, critical pedagogy offers students and others – outside of an officially sanctioned script – the historically and contextually specific knowledge, skills, and tools they need to engage in what the philosopher and Czech president Vaclav Havel calls “the richest possible participation in public life.” Needless to say, such tools are not pre-given but are the outcome of struggles, debate, dialogue, and engagement across a variety of public spheres.

Havel’s comments suggest that progressive educators must address the task of defending schools

as essential to the life of the nation because they are one of the few public spaces left where students can both learn about and engage in the experience of democracy. In the face of ongoing corporate takeovers, the increasing commodification of the curriculum, and the growing interest in students as consumers rather than critical citizens, educators must consider mounting a collective struggle to reassert the crucial importance of public education as a public good as opposed to being merely a private good. At issue here is providing students with the educational opportunities to recognize the dream and promise of a substantive democracy, particularly the idea that as citizens they are entitled to decent public services, such as housing, health care, health insurance, security, financial support during hard times, and most importantly, some power over decision making.

While this list is both schematic and incomplete, it points to a core of theoretical considerations that offer a beginning for advancing a more public vision for schools and colleges of education. Hopefully, it suggests theoretical tools for constructing new forms of collaboration among faculty, a broadening of the terms of learning for teachers, and new approaches toward interdisciplinary research that address local, national, and international concerns. The potential that cultural studies has for developing forms of collaboration that cut across national boundaries is worth taking up.

But like any other field or area, cultural studies is marked by a number of weaknesses that need to be addressed by educators drawn to some of its more critical assumptions. There is a tendency in some cultural studies work to be simply deconstructive, that is, it refuses to ask questions about the insertion of symbolic processes into societal contexts and their imbrication with power. Any viable form of cultural studies cannot insist on the primacy of signification over power, and in doing so reduce its purview to questions of meaning and texts. Within this discourse, material organization and institutional power disappear into culture. In opposition to this position, cultural studies needs to foreground the ways in which culture and power are related through the study of symbolic forms and meanings with the study of institutional power.

Moreover, cultural studies is still largely an academic discourse and as such is too far removed from other cultural and political sites where the work of public pedagogy goes on. In order to become a public discourse of any importance, it will have to focus its work on problems that are more public and pressing in terms of their relevance to address important social issues, whether they be drug policy legislation, the widespread attack by corporate culture on public schools, the ongoing attack on the welfare system, or a host of other issues.

In addition, cultural studies theorists have to examine their own formative histories and political and cultural ideologies in order to determine how they might be locked into the very systems of power they are attempting to get out of given that they often exercise power in and through the very institutions, cultural relations, and practices of the systems of which they are critical. This suggests registering and making visible our own subjective involvement in what we teach, how we interact in the classroom and other cultural sites, and how we locate, mediate, and defend the nature of the authority we exercise as teachers and cultural workers. Authority in this instance should become not simply the subject of social critique but also part of an auto critique of our own location and pedagogical practices within institutions that make us both complicitous and at the same time offer opportunities to push against the grain, undue the authority of the academy and other dominant institutions, while simultaneously opening up spaces of resistance and possibility.

Finally, if cultural studies theorists are truly concerned about how culture operates as a crucial site of power in the modern world, they will have to take seriously how pedagogy functions to secure and challenge the ways in which such power is deployed and resisted both within and outside traditional discourses and machineries of power, and as such suggests taking seriously the role that educators and other cultural workers might play as public intellectuals. Unlike traditional vanguardist or elitist notions of the intellectual, cultural studies should embrace the notion that the vocation of intellectuals be rooted in pedagogical and political work tempered by humility, a moral focus on suffering, and the need to produce alternative visions

and policies that go beyond a language of critique. On one level this means that cultural studies is important because it takes on the task of establishing and struggling over institutional spaces and practices that might produce public intellectuals. What critical educators need to stress is the need for cultural workers to struggle not only for the institutional space necessary for public intellectuals to have a voice but also for a cautious pedagogical regard for striking a critical balance between producing rigorous intellectual work, on the one hand, and exercising authority that is firm rather than rigid, self-critical and concretely utopian rather than repressive and doctrinaire, on the other. Rather than denouncing authority, those who engage in cultural studies must use it to organize and defend their cultural work, but at the same time they must avoid committing forms of pedagogical terrorism by allowing the authority they use and legitimate to be held up to critical scrutiny.

If cultural studies is to address its role as a public pedagogy, it will have to provide a new language for educating teachers, students, administrators, and others around the issue of civic leadership and public service. In this perspective, making the pedagogical more political as a central dynamic of cultural studies is fashioned not around a particular dogma, but through pedagogical practices which promote the conditions for teachers, students, and others to be critically attentive to the historical and socially constructed nature of the locations they occupy within a shifting world of representations and values. At the same time, such a pedagogy is about more than cultivating the capacity for critical understanding and engagement; it should also be about encouraging students to undertake strategies of transformation, strategies that locate students as the subject rather than the object of history, strategies that affirm forms of education that provide the conditions for students to learn how to govern rather than be merely governed.

Cultural Studies in Science Education

Christine L. McCarthy

University of Iowa, Iowa City, IA, USA

Introduction

The fundamental nature of modern science and, consequently, the proper methods of teaching science, have been extensively critiqued by theorists in the field of Cultural Studies of Science Education (CSSE). The launch of the journal *Cultural Studies of Science Education* in 2006 marks a key point in the history of the CSSE field. This journal focuses on research that understands modern science and science education to be particular cultural forms of establishing belief, embedded in, responsive to, and determined by larger cultural contexts. Holding that modern “western” science is a but an outgrowth of a western and/or European culture, the privileging of the methods and the resultant knowledge of western science is to be challenged, critiqued, and ended. The cultural positions of non-western peoples, and in particular the endemic, local sciences of each such population, are to be recognized as worthy of the same intellectual respect accorded to western modern science. The CSSE body of literature includes: pedagogical research about ways to teach science that eliminate the domination of school science by the newly de-privileged western modern science; qualitative research into forms of cultural oppression considered pervasive in the teaching of western modern science; and theoretical/philosophical research that sets out the commitment of the field to the coequal valuing of distinctive locally dominant cultural ontologies, epistemologies, and inquiry methods. Conceptualizations of science, and of science education, its purposes, and practices, must change accordingly.

CSSE scholarship has been and currently is strongly influential in the field of science education. But, it is also true that the fundamental intellectual commitments of CSSE are controversial. It is necessary to examine both aspects of the field to provide a thorough account of the CSSE field. Representative examples of the work in the field of cultural studies of science can be found

in Roth, W. (Ed.) (2009) *Science Education from People for People: Taking a Stand(point)*, in Roth, W. (Ed) (2010) *Re/structuring science education: Reuniting sociological and psychological perspectives*, and in Roth, W., and Barton, A.C. (2004) *Rethinking Scientific Literacy*.

Cultural Studies: The Broad Field

The cultural studies of science and science education constitute a subdivision of the broader field of cultural studies and must be understood in that context. Gilbert Rodman (2015), in *Why Cultural Studies?*, examines the purposes, methods, and social necessity of cultural studies investigations. Rodman argues that the field of Cultural Studies provides a much needed critique of elements of currently dominant cultural beliefs, norms, and practices.

Rodman applies the methods of cultural studies to the cultural studies field itself. He identifies problems in the field, and considers that the field in need of critique (Rodman, p. 4). Rodman believes that a regimen of “self-reflexivity” is essential if the field of cultural studies is to remain intact and able to serve its social critical function.

Cultural Studies is a well-established research field which was developed in its early years at the Centre for Contemporary Cultural Studies (CCCS) at the University of Birmingham (Rodman, p. 12). But it is difficult to clearly delineate the field or to give a descriptive account of its characteristic research focus and of its methods of inquiries. This is because the field has grown so precipitously and has garnered so many adherents that an exceedingly broad range of research topics and methods have come to gather under the heading of “cultural studies.”

This leads Rodman to identify that one of the problems the field must face is the fact of its own excessively diffuse and porous conceptual borders. According to Rodman, “the range of projects that currently travel under the ‘cultural studies’ banner is too diffuse — and too mutually incompatible — for most of the people claiming the term for themselves to actually be speaking about the same [general] project” (p. 35). Rodman sets out to formulate a prescriptive definition of what sort

of activities should properly count as cultural studies work, “to build a definition around a vision of what cultural studies is supposed to be.” (p. 37).

The principal criterion Rodman arrives at is that genuine cultural studies work must actively engage with a social-political issue of pressing cultural concern. The work must have a political purpose and a distinctive political stance. While the political stance of cultural studies work varies, it never strays far from its original affiliation with the political left (p. 43). Problems should be related to “real-life” social injustice; particular problems must be understood in their broader context (the criterion of breadth); and inquiries must have the aim of resulting in genuine knowledge of the social and nonhuman dynamics of the situation that lead to the problem (the criterion of depth).

The analysis must itself be, at the same time, intellectually genuine, that is, its findings must be undetermined by the leftist political commitments of the cultural theorist. The object is to gain genuine knowledge of the dynamics of the situation being studied, so that actions may be undertaken, with some hope of success, in reforming the situation in accord with a positive, leftist ideal end State.

The cultural studies ideal, on this interpretation, would seem to require the investigation of the dynamics of a social situation which is considered to be problematic, by means of the best modern scientific methods available, so that the dynamics may be known, and the knowledge may be used in guiding action toward the achievement of a desirable, and leftist, future state of affairs. The value of the tentative new knowledge is tested in practical activity, and revised and refined to more accurately correspond to the cultural dynamics that caused the initial situation of social concern.

This, one should note, appears to be the very model of a western modern scientific inquiry. Rodman, however, does not see the matter in this way and speaks of cultural studies as differing from other academic disciplines in that it is “an agenda driven project” (p. 52).

Rodman ruefully acknowledges that the cultural studies field has largely failed to meet this practical criterion for success. Cultural studies “has ‘failed’ to bring about an end to racism, patriarchy, heterosexism, colonialism, or

capitalism. . . even on a local level, even for a short period of time” (p. 52).

Cultural Studies of Science Education

Given Rodman’s analysis, one is moved to ask, why cultural studies of science and science education? Does this subfield meet the criteria of cultural studies at large? In what respects does it, and does it not, count as cultural studies?

It seems clear in reviewing the work published in the flagship journal that cultural studies of science and science education does largely take up what are considered to be social problem situations of injustice and cultural domination related to science and science education. Work in the field is thus purpose-driven, and it draws on the moral force of leftist political commitments. Given the wide scope of the issues taken up, from the practical problems of pedagogy, to the nature of science, to the nature of knowledge, truth, and reality, the CSSE field meets the criterion Rodman sets out for breadth of inquiry. But, does it meet Rodman’s demand for depth?

This is the point at which critics of CSSE tend to find problems with the field. The problem alleged is that cultural studies of science and of science education fail to properly understand the nature of modern science, the cultural conditions required for its occurrence, the intellectual and social dynamics of its production of knowledge, and the relations of economic and political power that form its social context, in the relation of modern science to social injustice (see McCarthy 2014).

Cultural studies’ purpose, as explicated by Rodman (2014), is to serve the interests of social justice, as that is understood from a politically leftist perspective. To do that effectively, what is required is knowledge of the problem, i.e., knowledge of the social dynamics of inequitable power relations and the political and economic causal factors operative in the situation. Each particular case must be understood in the social and material contexts that condition the occurrence and persistence of the social problem.

When modern scientific knowledge itself is taken to be one of the chief causal factors leading to global social injustice, as it is in the CSSE literature,

paradoxes emerge. Knowledge (western modern, wm) is initially considered necessary to successfully address cultural problems of injustice, but knowledge (wm) is rejected on grounds of cultural injustice. A new conception of knowledge, knowledge (cultural studies, cs), is developed. But it is unknown whether knowledge (cs) will serve as well as knowledge (wm) in reforming cultural relations. Critics argue that knowledge (cs) is deeply flawed and cannot adequately serve the purposes of cultural reform. CSSE, through this reasoning, appears to be vulnerable to the charge that its substantive conclusions regarding the nature of scientific knowledge with respect to cultural origin are not only philosophically misguided but also such as to be inimical to actually achieving the fundamental social justice purposes of legitimate cultural studies work.

Cultural studies of science and science education sets out, not with a critique of the practices of modern science and the negative cultural effects of the current social context on the practice and use of modern science, but with a wholesale rejection of the value of modern science as a cultural phenomenon. The cultural problems related to modern science are addressed only dialectically, with a creative re-envisioning of the nature of science. This requires revision of the set of interrelated philosophical concepts that are fundamentally related to modern science. When modern science is reconceptualized, conceptions of scientific knowledge, criteria for the justification of scientific knowledge claims, the methods of acquiring scientific knowledge, and even the fundamental concepts of truth and reality must all change accordingly. But, though the dialectical erasure of modern science might succeed in the academy, in fact modern science remains, and so do the genuine cultural, social, political, and economic problems associated with it. The field of cultural studies of science, in tackling these questions, moves beyond the politically oriented study of cultural conditions, to support the social activism of Cultural Studies *simpliciter*, and into the domain of philosophical work. This is in keeping with the Cultural Studies commitment to interdisciplinarity and “border-crossing.” The correlative risk in multidisciplinary work is that the work will suffer, to varying degrees, from superficiality of treatment (see Rouse 1999).

The Multiscience Thesis in the CSSE literature

Multiscience goes by many names in the CSSE literature – one finds multicultural science, ethno-science, pluralistic science, indigenous knowledge (IK), and traditional ecological knowledge (TEK), among others. Indigenous peoples are generally considered to have been culturally isolated to a significant degree from western culture.

The multiscience thesis, in its various permutations, is endorsed without exception in the cultural studies of science and science education movement. Clearly, it involves the repudiation of the concepts that the early sociologist of science, Robert Merton, in 1938, found to be fundamentally characteristic of modern science (see McCarthy 2014).

What are the conceptual changes in the nature of science that are required? First, the conception of knowledge is revised. The conceptual distinction between knowledge, on the one hand, and long-standing belief systems of cultural groups, on the other, is collapsed. “Knowledge” loses its distinction as an especially useful subset of beliefs, beliefs that have been tested most rigorously for accurate statement of recurring dynamic interrelations in the world, via active practices specifically designed as tests of the putative knowledge. With this conceptual collapse, every long-standing belief system is counted as fully legitimate knowledge.

Constraints on the methods of production of the belief systems that currently distinguish modern science from mere belief are radically loosened, so that even belief systems originating in revelations, visions, and dreams can be counted as scientific knowledge. Persistence over time is taken as a legitimate test of the claims of belief systems to count as knowledge. Every long-sustained culture has cultural beliefs and practices which have persisted over time – and so every such culture has its own fully legitimate form of scientific knowledge. All cultures, thus, by (re)definition, have culturally based scientific methods and bodies of scientific knowledge, and all are held to be worthy of equal epistemic respect. Problems of social injustice arise when the indigenous science of a culture is disrespected or considered to be of inferior quality to that of the western modern science and scientific knowledge. That science, distinguished only by having originated in western cultures, becomes just one of any

number of local culturally based sciences. Dialectically, all cultures, even those whose belief sets conflict with the knowledge of western modern science, can be considered to be possessed equally of legitimate scientific knowledge.

A particularly well-developed example of the multiscience thesis can be found in Peat’s 2005 treatise, *Blackfoot Physics*. Peat, himself a theoretical physicist, describes indigenous science as “a science of harmony and compassion, of dream and vision, of earth and cosmos, of hunting and growing, of technology and spirit, of song and dance, of color and number, of cycle and balance, of death and renewal” (p.8) and presents an account of indigenous physics, its content, and methods that is in important respects different from western modern physics. Vine DeLoria, Jr.’s *Red Earth, White Lies: Native Americans and the Myth of Scientific Fact* (1997) provides another example, stating that “The non-Western, tribal equivalent of science is the oral tradition, the teachings that have been passed down from one generation to the next over uncounted centuries. . .[it] explains the nature of the physical world. . .” (p. 360). Deloria (1997) draws a sharp contrast between the traditional knowledge possessed by Native American peoples, developed over eons of successful living, and the knowledge developed via western modern science, and rejects the latter. “Validity and verification in science primarily consist of a willing conspiracy among scientists not to challenge the authorities in the field and to take the sincerity of colleagues as insight” (p. 35).

Cognitive/Affective Essentialism in the CSSE Literature

Another problematic thesis arises in feminist epistemology and theories of distinctive women’s ways of knowing. These ways of knowing are claimed to fit poorly with the “male ways of knowing” that have shaped the development and nature of western modern science. This mismatch is thought to account for the cultural phenomenon of low participation of women in the fields of western modern science, and in the difficulty and/or lack of interest of female students in the study of modern science. This is often presented as a thesis of biological essentialism, though it is also interpreted as in part a culturally generated and maintained phenomenon.

This situation is a cultural-political pedagogical problem worthy of investigation by cultural studies theorists. It is addressed in much of the feminist cultural studies work, first, by accepting the thesis of an essential female cognitive difference, and second, by attempting to develop a new conception of science that would be better suited to women. Brickhouse (2001) states that “Science cannot produce culture-free, gender-neutral knowledge because Enlightenment epistemology of science is imbued with cultural meanings of gender” (p.283). Further, “culturally defined values associated with masculinity (i.e., objectivity, reason, mind) are also those values most closely aligned with science. . .scientific was also defined in opposition to feminine.”(p. 283).

Having accepted the theory of essential gender-based differences in cognition, resolution of the cultural problem of equitable access to scientific knowledge and professional access to careers in science has been deflected from the path of political activism into the intellectual project of developing a new conception of science that would be more congenial to women’s ways of knowing. The acceptance of feminist epistemologies, ways of knowing, of learning, of teaching, and of doing science, has become a consistent, and perhaps required, theme in the cultural studies of science and science education literature.

A similar analysis is made with respect to nonwhite persons. The assumption is adopted that western modern science is, in a deep sense, foreign to those not of European ancestry. This is often understood as a phenomenon of cultural difference but at times verges toward a biological essentialism. A prominent theme in the literature is the ill-fit between the assumptions and norms of western modern science with indigenous persons.

Conclusion

The theses of the cultural studies of science have had a considerable effect on the theory and practice of contemporary science education. Work in this area of science education is serving to radically reform science education and thus affects the apprehension of the nature of science in the larger society. An implicit theoretical commitment of Cultural Studies at large is the radical reformation

of the cultural conditions that promote social injustice, as seen from a leftist perspective. But successful reform requires an accurate understanding of the extant operative cultural conditions. Whether the cultural studies of science’s philosophical analysis of science, and the revisions in the concept that are promoted, will be adequate to the task remains an open question.

Curriculum as a Governing Device

Introduction

Curriculum

The meaning of the concept of a curriculum is elusive. It is used to establish goals, often their content and, in some cases, methods for teaching. There are, therefore, three types of curricula: those that state goals, those that state goals and content, and those that state goals, content, and methods for teaching. Since the 1990s there has been a fourth type – measurable outcomes that function as curriculum stating what is measurable knowledge. The very meaning of a curriculum as a governing instrument has changed. Once a plan for the intended content, curricula are now more of assessment requirements. Hence, the concept of a curriculum once meant the intended outcomes

that are supposed to govern the teacher's work. The curriculum was “translated” by teachers into strategies for teaching. This was the professional core. The instruments for measuring outcomes have now been given the role of intended outcomes themselves, and the teachers have to administer tests created outside their control.

Background

The term *curriculum* was used already in early Anglo-Saxon times. The word stems from the Latin word “currere” (to drive, move on), and was related to the word “cursus,” meaning a “track.” Petrus Ramus (1515–1572) was probably the first to use the word curriculum to signify goals and content for teaching. If we consider the meaning of the word *curriculum*, what it includes and how it is used, we can see how the history of its meaning reflects fundamental lines of the history of public education and schooling. In medieval times, the terms “stadium” or “ordo” dominated, and later “ratio,” “formula,” and “institution” were used.

During the sixteenth and seventeenth centuries, the word curriculum was used more and more to indicate the sequential arrangement of material in time; this usage is returning into fashion. At the University of Glasgow, the term curriculum was used during the seventeenth century to designate a course. Within the Jesuit order, a special organization of studies was formed, for which Ignatius of Loyola (Íñigo López Oñaz y Loyola, 1491–1556) constructed a curriculum for the education of servants of the Jesuit order (*Ratio atque Institutio Studiorum*). This was composed as a plan/scheme (*ratio*) for selection (*institutio*) that had to be composed from a set, or canon, of knowledge (*studiorum*). During the nineteenth century, the word curriculum was used in many universities around Europe. During the Enlightenment, however, the word curriculum came, to be replaced in Germany by “Lehrplan” (Blankertz 1982). In the Nordic countries, the term shifted, partly depending on which juridical context the goals and content of public education were regulated. In Sweden, for example, during the Catholic era, there was a decree regulating what each

citizen was required to learn by heart – Ave Maria, Pater Noster, and Credo. With the Reformation, public education became important for nation building and the establishment of the Lutheran State church. Demands on reading ability were paramount. In Luther's words: "Reading is a way directly connect with the words of God." The curriculum was the textbook *Luther's Small Catechism*. The duty of controlling how well people could read and how well they had learned the catechism fell to the Church. It was not possible to marry in Sweden if the would-be parents did not pass an examination in reading. The regulation of public education was a chapter in the Church Act. In the Act of 1686, the work of the parish clerk as a teacher was regulated, and the parish priest duty monitored the level of literacy in the parish. With time, more and more control and supervision was taken over by the State. In 1723, a law was passed placing responsibility for the education of children on their parents. Compulsory schooling was introduced in Europe during the eighteenth and nineteenth century. In Portugal, the law came into force in 1759, in Prussia 1763, in Denmark 1814, and in Sweden 1842 – just to give a few examples.

In most European nations, the curriculum is a national document and has a legal status. In the United States, curricula vary between and even within States. In Europe – mainly in the Nordic countries and in Germany – the word "curriculum" refers to content, while the term didactics covers instruction, methods for teaching, and the scientific rationale behind choices of instructional methods. Here the concept of a curriculum will be used to cover goals and content. Curriculum theory is therefore an explanation of how goals and contents are selected, formed, and distributed.

The Development of Curricula

There are four instruments for political governing (Lundgren 1981). This is simply the juridical regulation. The other three instruments are curricula, economy, and evaluation/control.

The construction of curricula (selection of goals and content, and the ideas behind structuring the content) for a public school system mirrors

national history and what, in a national context, is considered to be knowledge. Ancient Greek education had an impact on the ultimate goal of education of free men (wisdom: Paideia) and the organization of subjects in the curriculum of the medieval university (trivium, grammar, logic, and rhetoric, and quadrivium, arithmetic, geometry, music, and astronomy). The later division of curricula into humanities and science is a classification that is still in use. With the development of printing techniques, textbooks were commonly used to teach the curriculum. During the seventeenth century, the textbook, as a pedagogical text, was developed. The work of Johan Amos Comenius (1592–1670) was influential in the formation of the school systems of Europe after the 30-year war. He used texts in combination with pictures. Important textbooks included the book *Orbis sensualium pictus* (*The Visible World in Pictures*). In *Didactica Magna*, he presented a plan for the organization of a school system.

A change in how education was perceived and the rationale behind the organization of content in curricula began in the nineteenth century. There was a change from seeing education as reproduction of classic canon in which the mastery of Latin and ancient Greek was both a prerequisite for access to classic texts and for the formation of the intellect. New subjects, such as modern languages and the empirical sciences, were introduced into curricula. The founder of Humboldt-Universität zu Berlin, Wilhelm von Humboldt (1767–1835), formulated a program for a free university based on research built on the principle of autonomy for teachers and students (*Lehrfreiheit und Lernfreiheit*). This program of education for *Bildung* was a type of curriculum. The idea also came to influence the content and direction of upper secondary education.

Since the nineteenth century, curriculum construction has been increasingly international. The progressivist movement in Europe and the United States at the beginning of the twentieth century is one example. Influential thinkers included John Dewey in the United States, Georg Kerschensteiner in Germany, Jan Ligthart in Holland, Elsa Köhler in Austria, and Ellen Key in Sweden.

Especially after the Second World War, the rationale behind curriculum construction became

more and more internationally oriented. Today, the outcomes of the national public schools are related to international results. In the 1950s, studies of economic growth and investments in education showed that investments in education were related to growth in GNP, which in turn strengthened efforts to find new ways to improve education and make it more effective. The Human Capital Theory was established, which resulted in two main outcomes. The first was the tendency to focus on cognitive processes to create curriculum guidelines and didactic principles. The second outcome was the formation of effective teaching technology. The Woods Hole conference at the end of the 1950s became the starting point for a period of curriculum development in which the work of Piaget had an important influence (Bruner 1960).

An International Curriculum?

An increased awareness and knowledge of the economics of education sharpened arguments about the importance of education as an economic investment both for the individual and for society. More global markets called for competitive national systems. The launching of Sputnik in 1957 had an impact not only on the American education system and curricula. It also changed the discourse about curriculum content and its efficiency and evaluation. It is interesting to note that similar discussions were held in the Soviet Union, where researchers such as Vygotskij had similar opinions, which were used as a basis for research that was of relevance for curriculum development.

The year after the first Sputnik was launched, the International Association for the Evaluation of Educational Achievement (IEA) was founded. The idea was to build a network of researchers that developed tests designed to be used in comparative studies. The IEA was, in the beginning, a research endeavor, but with time educational administrations became involved.

Hence, the Cold War produced an interest in comparative international testing. The international comparisons of results were easy to fit into the political agenda at a time where opinion in support of competitive educational systems was strong.

These curriculum reforms emanating from the United States had an impact in most industrialized

nations. The work of the IEA strengthened the internationalization of curriculum development. The results of international assessments influenced political ideas about how to govern goals and content in relation to measurable outcomes. Within education, the idea of governing by goals and results was central to reform long before the New Public Management was coined. Education and teaching is always a process formed by goals, content, and results. During periods of change, this is more evident than in periods of stability.

When governing of education relies on measured outcomes, the validity of the tests is crucial. The Dutch mathematician Hans Freudenthal pointed out in the mid-1970s that the content validity of the international tests in mathematics was problematic (Freudenthal 1975). The construction of the items was adjusted to the Bloom taxonomy (Bloom et al. 1956) and not the actual content. Later, this criticism had an impact on discussions of the construction of tests in the PISA program.

During the 1970s, the industrial world faced changing economic conditions. The oil crises in 1973 and again in 1979, together with the increased international competition that resulted from them, put further pressure on educational systems to become more efficient and productive. With diminishing economic growth, the space for reforms was limited and new reforms had to be financed by increased efficiency. International assessments became more important, and national policies were broadened in scope and in the number of countries participating in them.

The 1970s was also a period of criticism of quantitative methods. It was pointed out that too little research had been directed toward teaching processes and too much attention had been paid to student behaviors. New models and methods were the solution to this state of affairs. During the 1970s, the educational systems were also under attack for failing in terms of efficiency and productivity, and educational research was thought to focus too much on statistics and psychometric analysis.

International tests and comparative studies have provided reference points. There was a shift in production in many countries in the 1970s. These changes had a clear impact on curricula. Largely to due to the increasing globalization of the economy

and the labor market, there was a change in how curricula were formulated. Nongovernment organizations, especially the OECD, played an influential role. With publications such as "Education at a Glance," the OECD delivered basic statistical data for comparisons between the member countries. In the beginning, the method used to report the results from various countries built on the IEA test – PISA (Program for International Student Assessment). Combined with neoliberalism, particularly ideas associated with New Public Management, measurability and comparability gained, and continue to gain, traction. Even if curricula are still national steering documents, it is measurable and comparable competencies that will count. The circle is to some extent closed. The curriculum is once again the answer to the question: what content is monitored and controlled?

The Curriculum and the Knowledge Society

Changes in production, economic developments, globalization, and other factors changed the external conditions for public education. The power of capital shifted to control of knowledge resources.

The transformation from a labor market structured by industrial production to a labor market structured by service production, circulation of products, reproduction, and above all the new information technology created new demands on education. It can be argued that the traditional organizations constructed to handle the economy and the political economy of modern industrialized society were no longer suited to handle a late modern society. They could not mobilize support for action. Accordingly, State institutions such as schools could not attract and build upon the interests of the clients or users. Political governance had to take other paths. One way out of the dilemma is to focus on outcomes and accountability in order to make education more transparent.

The expectations of increased efficiency and productivity called for concrete well-articulated goals and a steady direction. But what could be discerned was that the government and administration became weaker and fragmented. One explanation for this was the division into smaller political party fractions,

thereby forcing fragile coalitions. This, in turn, created an increasing sensitivity to lobbying and power pressure, which led to an overload of demands on decision-makers. These forces were contradictory to what was necessary for reforms in a new political context: that is, well-articulated goals and a steady direction. And here we can see the context to the variations in direction of curriculum discussions and suggestions. Two solutions to the weakening of political ability to govern can be discerned. One was to decentralize and another was to create pseudo-markets. To reform by decentralization through markets created a paradox. Decentralization and privatization demand clear rules and control. Within the administration, there were conflicts and competition. A consequence of this competition was, in some places, that goals for education were broadened in order to make the educational sector look as important or even more important than other sectors. Goals became more abstract when more clearly stated goals were needed. The arena for policy formulation could not get support for clear goals; instead goals became abstract and hard to realize. Ultimately the control increased, reinforced by the idea of national competition.

To meet these challenges meant that new ways of political governing had to be found. The two earlier mentioned solutions were to decentralize and/or open up for private education. This entailed deregulation which, in turn, requires re-regulation. What remains for the political center to do, if the educational system is to serve the purpose of promoting equality and reproducing a common value base, is to strengthen the curriculum and the evaluation system, i.e., to govern by goals and results.

With the new and rapidly changing economy and production, as well as globalization, and the rather dramatic changes in the volume and structure of knowledge, it has become more and more difficult to plan the selection and organization of content centrally. Higher levels of decentralization and more private schools mean that the central authorities have to govern content in new ways. The move from centralized to more local governance raises the question of where to place responsibility. Thus, a movement toward decentralization and marketization impacts upon the professional identity and capacity of teachers.

Access to information is rapidly increasing. Schools as institutions were created in a society with poor access to information. The way curricula and syllabi had been constructed reflects that. In this information-dense society, the gravitation point in curricula can no longer focus on the organization and order of content. We are approaching a Copernican turning point, in which curricula must be based on how knowledge is structured and articulated in basic concepts, theories, models, and competencies, which in turn must be expressed in terms of goals. To realize such transformation, curriculum construction and processes for curriculum construction must also change. This means new forms of specialization within the administrative bodies that represent interests other than the ones linked to specific content and thus specific school subjects.

There is one fundamental argument for governing by other types of goals and outcomes than before. Resources and rules can govern areas or sectors within which we have a profound knowledge or belief about the relationship between goals and methods. If we know that there is a clear relationship between – to take a simple example from traffic policy – speed, road conditions, and car accidents, we can execute governance by resources and rules. On the other hand, the less general knowledge there is of the relationship between goals and methods, the more governing by goals is applicable. This is also true when the competencies for future working life are hard to predict. However, this, in turn, demands that qualified personnel have the skills and knowledge to apply methods to specific circumstances.

Up to this point, I have tried to highlight the main changes in education during the 1970s and the 1980s. These changes and this discourse about education is the background to the OECD project INES.

PISA: An International Curriculum

In 1968, OECD established a specific center for Educational Research and Innovation – CERI Papadopoulos (2006). CERI became an important policy institute. In the late 1980s, CERI initiated the *Indicators of Education System* (INES). It is

an ambitious program to establish a system for education statistics in order to enable comparisons between countries within the OECD. Such a statistical system has an impact on national policies. International indicators deliver support for arguments on competitive strength. The background was the emerging knowledge society and the renewal of human capital theory. The statistics delivered from INES were published annually in *Education at a Glance*.

One problem that followed the project from the beginning was how to compare learning outcomes. The available international data that existed were those collected by the IEA. These data were used and presented in *Education at a Glance*. When INES got the data, they had been published in other forms and had lost their novelty. It was not possible to use the IEA data over time as the test varied between collections. The number of participating countries varied also, which gave the comparative analysis various reference points depending on the various data collections. The decision was taken to run an OECD assessment program – Program for International Student Assessment (PISA).

The test was to be “curriculum independent,” which means they were to measure the mastery of general principles and concepts and not a specific content. The criticism of the test used within the IEA program was thus avoided. On the other hand, the validity of the PISA test is still unclear. The design is built on measuring mathematics, reading, and science every third year and having items that make the results comparable over time. The tests are either short or extended. Every third year, one of the areas is tested with the extended test and the other two areas are tested with the shorter version.

The PISA program has had a tremendous impact on the politics of education. Countries that have not performed well have had “PISA-checks” and more or less every minister of education has declared that their country will be the future winner concerning measurements. The tests have influenced the discourse about education in general and about the curriculum and evaluation in particular. Curricula are now a governing device for what is measurable in tests.

The circle is closed. This article has highlighted how the meaning of the word curriculum has

changed over time, from being the road to wisdom (Paideia) to being a system for control (catechism), to being of use for work and society, to being an international system for control.

Debt, Education, and Decolonization

Jason Thomas Wozniak

Introduction

Financial debt has had a major role in defining colonial and neocolonial world history. Likewise, it has historically influenced education and plays a central role in shaping education theory, policy, and practice in the contemporary global neoliberal economy. Linda Martín Alcoff (Alcoff 2014) has written that “Decolonizing education requires first and foremost a thorough and comprehensive critical analysis of colonialism itself, in all its subtle guises” (p. 92). With these words in mind, and with a focus on the Americas, the first section of this short piece selectively highlights debt’s role in colonial conquest. Combining historical evidence and contemporary critical theory, the second section of this article traces how debt

influences educational experience. Finally, building on the work of Walter D. Mignolo (2011) and other decolonial theorists, it is suggested that “decolonial thinking and doing” within education, and as educational praxis, emboldens resistance against the colonizing forces of debt.

It is important not to omit a significant detail about the debt-education matrix that will be discussed below. W.E.B. Du Bois (2008) famously remarked that “the problem of the Twentieth Century is the problem of the color-line” (p. 3). In the twenty-first century, there exists a debt color-line. Debt, in the realm of education, is incontrovertibly *not* colorblind. Traditionally and fervently, debt has been used worldwide by colonial powers, e.g., European and North American States, and financial capitalist institutions like vulture hedge funds to subjugate marginalized groups. Today, it most severely impacts the educational experiences of these same groups of people.

Colonial Dispossession by Debt and Debt’s Influence on the *Ego Conquiro*

The story of debt’s role in shaping the darker side of colonial modernity (Mignolo 2011) often remains in the shadows. To cite one example of debt’s highly influential but largely unknown part in affecting colonial modernity, consider the following. Some of modernity’s most famous

conquistadors like Balboa, Pizarro, Francisco de Montejo, Pedro de Alvarado, and Hernán Cortés share a crucial commonality: They were all heavily indebted. An examination of the indebted history of Cortés demonstrates just one of the ways in which debt was a key factor in provoking and enabling accumulation by dispossession in the Americas. Colonial historical evidence also licenses the claim that debt should be given deeper deliberation in the analysis of the constitution of what Enrique Dussel (2000) has termed the *ego conquiro*.

Cortés arrived on the American mainland in severe debt. As Bernal Díaz de Castillo, who accompanied him, wrote, “(Cortés) was very poor and much in debt, despite the fact that he had a good estate of Indians and was getting gold from the mines” (Díaz in Graeber 2012, p. 316). As the anthropologist David Graeber (2012) has shown, Cortés’ marauding and butchering of indigenous peoples was motivated not only by a hunger for fame, certain perceived obligations to the Spanish Crown and God, but also by a deep desire to be free of debt.

Of course no one person can instigate genocide alone. Cortés enlisted the help of 600 men to launch his expedition on the mainland. Much like their captain, these soldiers coveted fame, fortune, and the desire to liberate themselves from debt, debt they owed to Cortés himself. By the time the Aztec capital Tenochtitlan had fallen, Díaz could state, “We were all very deeply in debt” (Díaz in Graeber 2012, p. 317). To make matters worse, for the indigenous population that is, in order to free himself of the men that most complained of their indebted status, Cortés, according to Díaz, “determined at once to get rid of the most troublesome fellows, by forming settlements in those provinces which appeared most eligible for this purpose” (Díaz in Graeber 2012, p. 318). Lamentably, Graeber (2012) reminds his readers, “these were the men who ended up in control of the provinces and who established local administration, taxes, and labor regimes” (p. 318). What must be taken account of here, and what Graeber exposes so well, is that “the frantic urgency (to pay back) debts” (p. 318), which were interest bearing and thus compounding, played no small role in influencing

the unheard of amounts of dispossession and destruction of indigenous peoples by early conquistadors like Cortés.

Limited space does not allow for extensive rumination on the degree to which the subjectivity of *ego conquiro* (I conquer therefore I am), which Dussel (2007) has argued predates Descartes’ *Cogito ergo sum* (I think therefore I am), and is an ontological category fundamental for understanding colonial modernity, is influenced by debt. But Graeber’s recounting of Cortés’ conquest, coupled with his analysis of the effects of debt on subjectivity and human relations, should at least cause a speculative pause. It very well could be that the *ego conquiro*, which according to Dussel is a self-expanding subjectivity that imposes its will to power primarily on those of the so-called Global South, is at least in part constituted by the force of debt.

Education as a Process of Shaping Indebted Subjectivity

Traditionally marginalized groups are disproportionately familiar with the ways which both debt and education can be used to impose ways of being and acting in the world on people. The historical record of education efforts aimed at postbellum African Americans, mainly in the southern United States, exemplifies this point. In her analysis of the ways in which emancipated slaves were fashioned into indebted subjects, Saidiya Hartman (1997) masterfully demonstrates how the convergence of debt and education has been and remains a central means of fabricating indebted subjectivity. Hartman describes how emancipation for slaves did not mark the end of bondage; rather, it marked the beginning of an era of “indebted servitude” (pp. 125–126). Moreover, according to Hartman, former slave owners, northern industrialists, and liberal reformers in the postbellum United States worked to guarantee that ex-slaves be “transformed into a rational, docile, and productive working class – that is, fully normalized in accordance with standards of productivity, sobriety, rationality, prudence, cleanliness, (and) responsibility” (p. 127).

To accomplish this task, a debt-education matrix was utilized. Postbellum education initiatives aimed at freed slaves were a medium for constructing indebted subjects and contributed to what Du Bois (2008) described as the “pall of debt” (p. 87) that hung over the American south. After the American Civil War thousands of ex-slaves were forced into debt peonage. Additionally, through a variety of pedagogical techniques, chief of which involved conduct books like Jared Bell Waterbury’s *Friendly Counsels for Freedmen* (1864) or Reverend Issac W. Brinckerhoff’s *Advice to Freedmen* (1864), they were taught, according to Hartman (1997), to responsibly honor financial obligations meant to entrap them, and supposed debts of freedom towards benefactors and the nation, that at once freed, and indebted them (p. 130).

Debt as a Neoliberal Apparatus in Education

Debt’s influence on education is not merely a phenomenon of the past. Maurizio Lazzarato (2012) has decisively demonstrated that the neoliberal era in which we currently live “has been founded on the logic of debt” (p. 25). Debt, Lazzarato maintains, is at the “strategic heart” of neoliberalism and “represents the economic and subjective engine” of the modern-day political economy (Ibid). It is important to understand, therefore, that education projects organized in accordance with neoliberal ideology are projects substantially saturated with the logic and force of debt. Today, debt is used with efficient intensity to produce twenty-first century versions of accumulation by dispossession in education. Furthermore, education experiences cultivated within a debt paradigm contribute mightily to the fabrication of contemporary indebted subjectivity.

By now it is widely known that past and present university students in the United States and elsewhere face a serious debt dilemma. Andrew Ross (2013) has reported that US university students graduate with debt loads averaging \$27,000. The total student debt load in the USA has reached an astronomical \$1.2 trillion dollars.

In his provocative essay on the current US student debt crisis in higher education, “The Pedagogy of Debt,” critical theorist Jeffrey Williams (2006) argues that “debt is not just a mode of financing but a mode of pedagogy” (p. 162). Williams highlights six specific lessons that debt imposes. Taken together, they advance the argument that the contemporary debt-education matrix has the ability to fabricate indebted subjectivity.

Williams (2006) contends that first, “*debt teaches that higher education is a consumer service*,” (p. 163, all italics in original) and that second, “*debt teaches career choices*” (p.164). The three lessons, that “*debt teaches a world-view*,” that it “*teaches civic lessons*,” and that it “*teaches the worth of a person*” (pp. 164–165), are most directly related to the ways in which debt plays a pedagogical role in forming the neoliberal indebted subject. Finally, debt teaches not only cognitive lessons but also emotional ones. This fact is clarified in what Williams states is the final debt lesson: “*debt teaches a sensibility or feeling*” (p. 165).

Missing from Williams’ persuasive analysis of debt are two key features. The first is attention to the fact that students of color are disproportionately beleaguered within the US student debt crisis. Research conducted by the social justice advocacy group *Demos* (2015) has clearly demonstrated the existence (Huelsman 2015) of debt-color lines. According to *Demos*, black and low-income students borrow more, and more often, to receive a bachelor’s degree, Latino/a and black students are dropping out of university with debt at higher rates than white students, and Associate’s degree borrowing has spiked particularly among black students over the past decade. Debt burdens are compounded for these students. Not only must they struggle to overcome inequalities at least in part created by debt in the past, but also their efforts to overcome said inequalities are weighed down by the fact that they must go into further debt for an education in the present. This education may, or may not, grant them greater opportunities for social-economic equality in the future, a future, it bears mentioning, that is already colonized by accrued education debts.

Secondly, when seen through a decolonial lens, the “pedagogy of debt” takes on important added dimensions. Debt structures, in part because of its ability to colonize the future, epistemic frameworks and ways of being in the world. It demands the rationalization and instrumentalization of ways of thinking and being. As such, debt contributes to the production, distribution, and organization of knowledge, and in doing so, it suppresses alternative knowledge, as well as alternative ways of being in the world. In sum, debt plays a role in reproducing what Alejandro A. Vallega (2014) has called the “Western modern instrumental, rationalist, productive, and subjectivist thought” (p. 219).

A decolonial perspective on the bonds between debt and education also illuminates the large-scale social consequences produced by debt coloniality. Puerto Rico provides a classic example of how debt today functions as a tool of accumulation by dispossession practices in education. The island’s current debt crisis highlights some of the ways that debt works as an apparatus of neocolonial economic pressure to transfer education resources from the public to private sectors. The journal, “The Progressive” (2015), has reported that since 2014, the Puerto Rican government, under pressure from creditors, hedge funds, and the US government, has closed 135 schools – about 10% of the schools on the island. Additionally, “Project 1456,” a new law pushed by neoliberal “reformers” to ameliorate the debt crisis, requires the closure of 400 more public schools – 30% of the remaining public schools in Puerto Rico. “Project 1456” also stipulates that the Puerto Rican government turn at least 15% of the island’s schools into *Lider* charter schools every 3 years.

Towards Decolonial Debt Resistance in Education

María Lugones (2010) has emphasized that decolonial resistance is neither an end nor goal, but rather a beginning. Most immediately, it reminds us that “we are also other than what the hegemon makes us be” (p. 746). For the rest of

this article, I consider a variety of decolonial possibilities that disable the force of debt at work in education and that aim to inspire the conceptualization of education as a liberatory process capable of decolonizing indebted subjectivity.

Three brief comments on the options to be discussed are warranted. The first is that decolonial theory teaches that decolonial debt resistance must engage in a range of different but interrelated struggles simultaneously. A multiplicity of logics and strategies, rather than a totalizing theory or praxis, must be developed. For example, while it is of obvious importance to wage political and economic struggle against indebted life, it is of equal importance to concomitantly strive for epistemic debt decolonization.

The second point is that divesting education from the undue impacts of debt necessarily entails the coupling of decolonial theory and praxis. Eve Tuck and K. Wayne Yang (2012) have astutely critiqued discourse in which colonization and decolonization are treated metaphorically. Both decolonial thinking *and* doing need to be continuously experimented with in the realm of education, and it is only during and after such experimentation takes place that the efficacy of these theories and direct actions can be fully evaluated.

Finally, one does not resist indebted life alone. Individuals must realize, as the activist groups *Strike Debt* and *The Debt Collective* have proclaimed, that they are not only not *a-loan* but also not *alone*, in their efforts of opposing the logics of indebted life and in their practices of being someone other than indebted subjects. One decolonizes “with someone else, not in individualist isolation,” Lugones (2010) reminds us, and despite the greatest efforts to vanquish decolonial collective ways of being, “these ways of being, valuing, and believing have persisted in the resistant response to coloniality.” (p. 754).

With the above in mind, and in an attempt to circumvent what Tuck and Yang (2012) have critiqued as decolonial equivocation, several concrete decolonial demands in education warrant consideration. The demands below are

purposefully “utopian,” utopian understood here in accordance with the Martinican philosopher Edouard Glissant’s (2005) conceptualization of utopia: “Utopia is not a dream. It is what we are missing in the world” (p. 16).

Decolonial utopian demands to address education debt burdens include, but are not limited to:

- Immediate and indefinite moratoriums on all municipal, State, and national government debt payments to education debt bondholders. Moratoriums on debt payments would be coupled with moratoriums on school closings related to debt. During these moratoriums, bond agreements need to be renegotiated, and terms for eventual education debt jubilee must be established. George Caffentzis (2013) highlights the successes of related demands in his analysis of the debt resistance movement “El Barzón” of the 1990s in Mexico. El Barzón, Caffentzis recounts, “is a mass organization of debtors that, at its height, had half a million members and chapters all over Mexico. It provided to its members both legal aid and ‘muscle’ to resist foreclosures and repossessions due to debt default.”
- A critical engagement with the problematic of settler colonialism with respect to debt. Debt has historically had a fundamental role in settler colonialism. Throughout history, indigenous groups have had their lands taken from them because of contractual debt agreements. Furthermore, it is on these lands that many schools and universities were built. There exists a moral obligation for communities worldwide to engage in discussions with sovereign indigenous nations on reparations for territories, especially discussions that address the occupation of lands by schools and universities. Contesting debt coloniality in this context would require the adoption of indigenous concepts and terms related to debt and reparations.
- The abolition of debt in countries like the United States, Canada, and others where university student debt burdens many. The said debt must be immediately *abolished*, not

forgiven. As Andrew Ross (2013), activists groups like the *Debt Collective*, and others (See the excellent collection of essays edited by David Palumbo-Liu on debt activism in the journal “Occasion” Vol. 7, 2014) have argued, the majority of indebted university students had no other choice than to go into debt to receive a college education. In other words, they did absolutely nothing wrong by going into debt, therefore why beg for forgiveness. Instead, demand debt abolishment.

Drawing on Mignolo (2007, 2011), it could be said that the above demands would be a part of broader efforts at “delinking” education from the forces of financial debt. Mignolo has described delinking as the decolonial process of inventing “decolonial visions and horizons, concepts and discourses” (2011, p. 312). Delinking opens up the possibility for the creation of decolonial knowledge, institutions, and subjects (Mignolo 2011 p. 9). In this way, we might think delinking together with the invaluable decolonial dictum “*Inventamos o erramos*” or “We invent or we error” from nineteenth-century philosopher and educator Simón Rodríguez. Significantly, delinking education from debt depends heavily on the ability to delink education from debt’s temporalities and pedagogies. This piece concludes with summaries of decolonial theories that might stimulate this.

Mignolo (2011) has asserted that colonization of the concept of time enables the control of subjectivity. Debt’s ability to colonize our notions of time, and its capacity to shape the rhythms of our everyday lives, is central to its power to shape indebted subjectivity. Lazzarato’s (2012, pp. 44–49) analysis enables us to briefly highlight several key characteristics of the temporal dimensions of indebted life. The temporality of debt is nonlinear. Debt creates a memory in a person of a future-to-come. This indebted future-to-come constantly travels back in time to haunt the present of the indebted subject. With a memory of debt ever hovering (like a specter), the indebted person ends up shaping one’s self and daily activities so that she will be

able to service her debt. The pace of life is set to the rhythm of debts owed; rational and calculative thinking determined by debt becomes the reductive norm.

Contemporary considerations on the decolonization of time must therefore take into account ways in which debt's temporality can be countered. And it is here where there is cause for optimism in education. Education can serve as a type of counterconduct to the production of indebted subjectivity; it is a privileged realm in which to counter the rhythms of indebted life *if* (admittedly a big one) educators and students cultivate education experiences composed of rhythms counter to those that debt demands. It is true that today debt's force in education shapes education rhythms in such a way that education is increasingly reduced to a process of shaping indebted subjects. But in very concrete ways this force can be resisted; it can be removed from educational experiences. Just as importantly, educators can, and often do, rethink pedagogies so that education experiences which cultivate temporalities exterior to the temporality of debt are brought into being.

Decolonial debt resistance in and through education with an emphasis on time and rhythm is further warranted if one considers the following. Mignolo (2011) configures decolonial thinking and doing as a process that involves the decolonization of time, remarking that, "decolonial thinking shall build arguments for the revival of the 'the de-acceleration of time'" (p. 179). In a similar vein, Nassim Noroozi (2016) has recently developed a notion of the "pedagogy of time" that as an "ethico-decolonial undertaking is committed to a different pace," a pace which "provide(s) enough time to generate space for the 'whats' and 'whos' that were excluded or relegated (and thus have been subjected to epistemic violence)." There is decolonial precedence for the move that Noroozi suggests. Simón Rodríguez maintained that "studying needs tranquility," a belief that, Argentine philosopher of education, Walter Kohan (2015) argues, represents Rodríguez's lifework of democratizing free-time for study for the most marginalized populations of nineteenth-century newly liberated Latin America. Frantz Fanon

(1968) explicitly linked rhythm with decolonization and the cultivation of decolonial subjectivity:

Decolonization never takes place unnoticed, for it influences individuals and modifies them fundamentally. . . . It brings a natural rhythm into existence, introduced by new men, and with it a new language and a new humanity. Decolonization is the veritable creation of new men. (p. 36)

Importantly, these theories help us think subjectivity, time, and pedagogy together in a way that allows us to reconceive education as a process of opening up ways of being in a globalized debt economy. They also share a commonality in that they avoid reinscribing colonial temporal practices in education by implying that a single dominant temporality cannot be forced on education experience. Rather, they point to the fact that heterochronic and polyrhythmic education experiences are fertile ground for a plethora of subjectivities to take root and be cultivated in.

Ultimately, what deserves contemplation is whether or not it is possible to conceive of and to cultivate education logics and practices which are exterior to the logic and force of education paradigms constructed by, existing within, and serving the contemporary neoliberal debt economy. Asymmetrical creditor-debtor relations sustain this economy. Such creditor-debtor relations entail, it could be argued from a decolonial perspective, what Enrique Dussel (In press) calls, a "pedagogics of domination." A decolonial option which counters this pedagogics is a Dusselian "pedagogics of liberation."

Enrique Dussel's immensely complex philosophy of education, most fully developed in his *La Pedagogica Latinoamericana* (1973), but only hastily referred to here, stimulates both the critique of pedagogies/pedagogics of debt/domination and the conceptualization of education theory and praxis exterior to said pedagogies/pedagogics. His philosophy of education opposes a dominating dia-lectic with a liberatory ana-lectic. Dussel (In press) has developed a philosophy of education in which "the educative process, by definition, negates the introjection of the system (de-struction) and affirmatively constructs exteriority through ana-lectic praxis of liberation, in

the permanent creative-innovative unity of teacher-student.”

More specifically, for Dussel (In press, italics in original), a “*praxis of a pedagogics of domination*” is based on the postulate that there is no other possible speech than that which expresses the meaning of the established world” and is contra to a “*praxis of a pedagogics of liberation*,” which is “based on the postulate that I myself never pronounce the revelatory word of the Other.” At the heart of liberatory pedagogics for Dussel is “mutual listening,” reception of, and responsibility to, rather than domination of, the Other. Dussel’s elaboration on this point deserves to be quoted at length:

Pedagogics demands *listening to the voice of the Other*. In pedagogics the Other’s voice signifies content revealing itself, and liberatory education can only begin with the revelation of the Other. The student reveals himself to the teacher; the teacher reveals himself to the disciple. If the child’s voice, the voice of the youth and the people, is not heard by the father, the teacher, and the State, then liberatory education is impossible. Mutual listening sends, and essentially, the other receives (though clearly with diverse meanings for one party). This sending and receiving is the *conditio sine qua non* of pedagogical love (*agape*) as extreme gratitude (Italics in original).

In sum, a Dusselian pedagogics of liberation counters the *ego conquirro* logic of debt pedagogies with the logic of the decolonial gift. If the pedagogies of debt can be said to seek to dominate and give shape to the Other, the pedagogics of liberation do the opposite by receiving the Other as a gift. Thus, a pedagogics of liberation offers the potential for a paradigm shift in education away from debt, and towards a paradigm of the gift, which, if we concur with Nelson Maldonado-Torres (2007), is essential to decolonial projects. “This is the precise meaning of decolonization,” Maldonado-Torres tells us, “restoration of the logic of the gift” (p. 260).

Introduction

This entry has three central aims. The first aim is to briefly outline the historical and contemporary use of the term “decolonial” and its related monikers of decoloniality, decolonization, decolonizing methodologies, postcolonialism, and indigeneity. The second aim is to highlight how the decolonial scholarship addresses the

relations between colonization, capitalism, and the production of difference through onto-epistemological frameworks of racism, heteropatriarchy, and (Western) schooling as a site of epistemic, linguistic, and cultural violence. In other words, I explore how colonial and decolonial logics of difference, hierarchy and violence shape macro and micro-level modes of existence. The third and final aim is to provide illustrations of contemporary efforts of decolonial education at its intersections in multiple spaces and places through a discussion of Anzaldúa’s border thinking.

At heart, decolonization works against the dehumanization and disposability of indigenous peoples; recovers and reinforces indigenous knowledges; protects indigenous jurisdiction over land, water, and agricultural rights; complicates border thinking; and explores hybridity or *mestizaje* as ways of knowing.

Notes on Decoloniality

Decoloniality refers to the everyday and ongoing efforts to challenge various forms of colonialism or coloniality in the past, present, and future. Leading contemporary scholar Walter D. Mignolo makes a distinction between decoloniality and decolonization. According to Mignolo, decoloniality refers to the active struggle against spiritual, social, political, and psychological colonization of indigenous peoples and their descendants by France, Spain, Italy, the Netherlands, and the United States (Smith 2000, p. 121). Like post-colonialism (see Tarc’s entry), decolonial scholars do not believe that the time of coloniality is over, even in nation-States or spaces that have so-called independence. While the praxis of decoloniality is made possible through historical anticolonial efforts, Mignolo and others argue that the concept of decolonization is tied to Cold War (post WWII) movements by indigenous peoples and their descendants across the Americas, Africa, and Asia. While some of these efforts towards decolonization created new real and symbolic sociocultural changes, many nation-States formerly ruled by external colonialism (vs. settler colonialism)

has left many countries in ceaseless states of conflict and crisis. In fact, some decolonial writers note that political, economic, and environmental issues may be worse after becoming formally independent from formerly sixteenth to twentieth century imperial rule. However, decolonial scholars contend that indigenous, enslaved, and colonized peoples have resisted and survived despite 400 years of extraction, exploitation, and dehumanization.

Decoloniality rejects the universalism of Western philosophy and instead argues that knowledge production is tied to local and concrete struggles against various forms of coloniality. Thus, decoloniality or what Mignolo calls “the decolonial option” favors analyses, art forms, and actions that are particular and begin from the ground up. There are many ties between decoloniality and indigeneity, specifically the emphasis on local knowledge, self-determination, and sovereignty. However, there are other areas of debate and discrepancy. For example, indigeneity reflects a commitment to the sustainability of culturally specific ways of knowing and being as reflected in epistemology, cosmology, spirituality, language, kinship, education, place-based knowledge, and tribal governance. Indigeneity also reflects the historical and contemporary need to emphasize tribal sovereignty, especially as a strategy to maintain legal and economic ties to treaty rights. In contrast, most decolonial efforts operate from the epistemological assumptions of cultural hybridity as well as the conditions of transnational politics of globalization. In addition, the latter group suggests that the role of nation-States has diminished due to the rise of transnational corporations and mass geopolitical migration (Spivak). Here, decoloniality and indigeneity (as well as postcolonialism) may be thought of as interrelated, complementary, or alternative perspectives but not synonymous in focus or methods.

Decoloniality assumes that social categories such as race, gender, and sexuality are inventions of colonial capitalism (Alexander 2006). As social categories linked to colonial capitalism, they hold symbolic and material significance for how individuals and groups experience the social world. Decolonial writers are interested in illustrating

how individuals, companies, and governments have mobilized these differences into sedimented hierarchies exploitable for conflict and profit. Scholars of decolonial theory at its intersections investigate how colonialism operates in tandem with race, gender, and sexuality to construct notions of the human (Lugones 2010), difference (Anzaldúa 1987 and Perez 1999), and citizenship (Alexander 2006).

Similarly, scholars/thinkers/activists involved in various decolonial options seek to intervene in efforts to render particular bodies *dehumanized and disposable*. Writing about the coloniality of gender, Argentinean philosopher Maria Lugones notes that women of color have been denied the status of human being since Columbian contact in two specific ways. First, European colonial capitalist ontologies imposed a categorical and hierarchical system of racialization and sexual difference. Though recycled through “moralistic” and “scientific” forms, these modes of invented difference and hierarchy have served as the basis for State sanctioned forms of violence, disposability, and lack of legal recourse from physical and economic injury. Second, the racialized colonial logic of human/nonhuman allowed European trespassers to sexually violate and dismember the bodies of indigenous women as primitive not-White, not-women likened to beasts. These practices of dehumanization carry on as women of color have been particularly subject to sexual and gender-based harm, violence, and even death. From the forced sterilization of Puerto Rican women by the US government to the police violence against Black and Latina women to the missing and murdered First Nations women across Turtle Island, women of color have been used and abused. Moreover the logics and structures of coloniality render women of color illegible as valued members of society and denied full citizenship and protection by the law. Thus, one of the strands or “options” of decoloniality specifically addresses the need for women of color to gain self-determination, reprojustice, and gender sovereignty.

Decoloniality works against *extraction and destruction* of local knowledges, cultural practices, and natural resources. Colonized groups

across the Americas, Africa, and Asia have witnessed the violent extraction and careless destruction of natural resources from water to land including sacred sites and precious metals. Furthermore, forced displacement as a result of the Indian Removal Act of 1830 (such as the Trail of Tears and The Long Walk in the United States) and compulsory residential schooling have literally cut off indigenous persons and communities from the place-based knowledge and created generational trauma. As Maori scholar and activist Linda Tuhiwai Smith (2012) notes, colonialism created a particular “disorder” to existing indigenous belief systems including relations between the self, the collective, and land. This disordering of native belief systems, also referred to as epistemic violence or epistemicide, particularly affected the role of women (and Two-Spirit persons) as knowledge producers, spiritual guides, and leaders in medicinal and reproductive activities. Thus, another decolonial option is to provide recovery and healing and growth to regenerate the creative, cultural and political resources necessary for survival in next 400 years. Here recovery not only refers to psychological healing and growth; it is also “that specific lands and designated areas become a priority because the bulldozers are due to start destruction any day now.” (121) The 2016 mass protection demonstration by the Standing Rock Sioux at the Sacred Stone Campground against the Dakota Access Pipeline (NoDAPL) is a good example of decolonization efforts in action. Termed as the largest indigenous uprising in the United States (sic) natives and allies have joined together to protect sacred tribal burial grounds, protect the sacred nature of water in general and more concretely to stop the possibility of myriad environmental, biological, and human disasters due to accidental spillage. Like indigenous efforts of decolonization by First Nations in Canada (sic), NoDAPL contends that installation of the pipeline allows corporations to violate treaty agreements.

In addition to land reclamation, decolonial praxis works for *language reclamation*. This effort takes a variety of shapes. First, as with many indigenous histories, native languages were systematically and literally beaten out of

tribal youth as they came in contact with and were forced to assimilate to British, French, Spanish, or Dutch language and culture within and outside of residential or other colonial schools. For nearly four centuries, youth and adults were punished for speaking native languages – thus creating many indigenous languages to perish along with the public displays of cultural and spiritual practices. Thus, one strand of language reclamation is at the very grassroots level to record and revitalize tribal language and education with the assistance of contemporary sociolinguistic and culturally sensitive pedagogical practices (Lomawaima and McCarty 2006).

Another strand of decolonial practice follows from mid-twentieth century postcolonial scholars such as Kenyan writer Ngugi wa Thiong'o, who argued that rejecting the hegemonic languages of English and French were necessary to the process of decolonizing the mind. For Ngugi, writing in the colonial languages was tantamount to alienation in the Marxist sense of the word. Thus, he chose to publish much of his work in his native Gikuyu. Fellow postcolonial scholar Gayatri Spivak praised Ngugi's stance on English as an imperialist tongue and the deleterious effects it would have for personal and collective struggles for freedom. However, she also noted how English became the language of globalization after World War II, and as such argued for the strategic use of English to reach a larger audience in transnational efforts of anticolonial mobilization. Consistent with a poststructural framework of the noninnocence of all power, Spivak stressed the complicity of all academic efforts to speak for and represent “the Other.” She writes, “Elite ‘postcolonialism’ seems to be as much a strategy of differentiating oneself from the racial underclass as it is to speak in its name.” (1999, p. 358) Here Spivak suggests that the failure of decolonization has resulted in the gendered postcolonial acting as a native informant of “those distant objects of oppression” (ibid, p. 360) of colonial, patriarchal, and class-based rule. Thus, one of the central claims in *A Critique of Postcolonial Reason* is the need for vigilant and responsible knowledge production among “those of us who become the globe-trotting postcolonials, ready for entanglements in new global

complicities.” (Ibid, p. 363). To do so, Spivak regularly insisted that English speakers, members of the metropole, and the ivory tower challenge themselves to be responsible to their subaltern counterparts by learning local languages, aesthetic, and cultural productions and securing the subaltern’s authority (jurisdiction) over native land, agricultural, and water rights.

Remapping the World: Decolonial Perspectives on Language and Space

While Ngugi, Spivak, and other scholars from the 1950s to early 1980s focused on the need for postcolonial scholars to read, write, and speak in their native language, much of decolonial scholarship during the 1990s and afterword began to think and talk about *language and space* in theoretical and symbolic terms. Specifically, authors such as Gloria Anzaldua (1987) shifted the discussion of language to incorporate questions of hybridity, difference, and ambiguity. In contrast to Ngugi’s claim that a rejection of the master’s tongue would lead to decolonization of the mind, Anzaldua’s framework of decoloniality began with the assumption that the lines between colonizer/colonized, master/native, native/Other are neither binary nor discrete due to the specific histories of colonization in the Americas. As Anzaldua notes, many Latin American territories (including the contested borders and boundaries between Mexico, Texas, and the southwest United States) consist of descendants of Spanish, African, Caribbean, and a wide variety of indigenous communities and citizens. Thus, the image of the “mestizo” serves as an organizing myth and national symbol for this population. “La malinche” (an enslaved indigenous female give to Conquistador Cortes) is considered to be the producer of the first “mestizo” – e.g., the Mother of a nation in which cultural hybridity is the norm. But as Anzaldua’s Latina feminist critique reminds us, the sexual and colonial violence of this history is often either erased or disappeared and leaves Mexicanas, Tejanas, and Chicanas living in the “borderlands” of multiple colonized territories (cultural, spatial, national, linguistic,

psychic, etc.). According to Anzaldua, what remains are the three mothers of la gente Chicana who serve as icons of ambiguity. She writes, “All three are mediators: Guadalupe, the virgin mother who has not abandoned us, la Chingada (Malinche) and la Llorona, the mother who seeks her lost children and is a combination of the other two.” (p. 30). Anzaldua suggests that a deluge of affective scapegoating (mostly misogynist hostility and ethnic shame) has led to a dichotomous framing of Latinas as trapped within the colonial matrix of virgin/mother/whore. Instead, she argues that argues for a more tolerant attitude of ambiguity that embraces of mestizo identity, difference, and cultural hybridity. Specifically, Anzaldua calls for “a new mestiza consciousness” or a “consciousness of the Borderlands (1987, p. 77).” Anzaldua notes that the Eurocentric way is to treat difference and multiplicity as adversarial because of the entrenchment of authoritarianism within hierarchical onto-epistemologies. Because of her culturally hybrid identity, the mestizo has to negotiate multiple and often conflicting belief systems, affective positions, and political stances. This framing of difference and hybridity as duality and opposition has left minoritized subjects with cognitive, emotional, and spiritual wounds. Rather than see these contradictions as deficit, Anzaldua contends that the mestizo develops a “tolerance for ambivalence.” (p. 79). She posits that the new mestiza consciousness requires the decolonial subject to wrestle with her embodied knowledge in a kind of “soul work” (including creativity and intense pain). Out of this struggle emerges a new sensibility, a tolerance for vulnerability, ambiguity, movement, and perpetual construction and deconstruction of ideas and capacity to form new alliances for personal and social transformation. This space, the Borderlands, is both real and imaginary. It serves as symbol of hope and possibility for education as a project of love.

Decolonial Education: The Borderlands Are a Metaphor, a Place, and a Praxis

Educational philosopher Troy Richardson (2012) calls to disrupt the coloniality of being in US

education that positions African, Latinx, and Native American youth as “primitive” or “enigmas” through the logics, practices, and structures of categorical subordination such as standardized testing, discipline policies, and even classrooms that antiassimilation pedagogies. In contrast, Richardson advocates for educators to consider “decolonial trans-ontologies” that reject colonial models of categorical subordination towards a “border thinking” that

entails a shift towards those physical borders where the complex forms and languages of being continuously emerge. . . . Through radical dialogues in these shifted locations we learn the pre-situations of such youth. Learning with minoritized youth in this way entails forms of bilanguaging wherein European ontologies lose something of their habitability. In those, perhaps, fleeting moments, decolonial trans-ontologies are more clearly recognized as the future which denies the colonial of being. (550)

Richardson’s call for philosophers of education and teachers to *learn with minoritized youth in the ways, forms, languages, and spaces they inhabit* reiterates the point that decolonial education not only affirms the “diversity of diversity” – but challenges the colonial model of education of philosopher/teacher/expert versus youth/ignorance/student-to- be classified, sorted, diagnosed, and evaluated.

Decolonial education employs critical and culturally relevant curriculum and pedagogy that incorporates the wisdom of elders and community members. Moreover, life histories are considered intellectual “gifts” (Lomawaima and McCarty, p. 12). An important part of decolonial education is the recognition that struggles against colonial struggles have a long history across the world and to allow people to see themselves as part of that legacy. Thus, learning the life histories of both the named “leaders” as well as the unnamed people whose specific contributions may have not been recorded in colonial accounts were just as important in historical struggles against decolonization. This is important for two reasons. First, decolonial education emphasizes the retrieval and distribution of subjugated knowledges and histories. Given the longstanding tradition of Western education to promote colonial perspectives as official

accounts of Being, Truth, History, Culture/Civilization, and Freedom, it is essential to actively disrupt the “un-coercive re-arrangement of desires” (Spivak 2004, p. 526).

Second, the praxis of remembrance, ceremony, and creative expression, or what Alexander (2006) calls “pedagogies of crossing,” all illustrate “the decolonial imaginary” in action (Perez 1999). Storytellers, artists, musicians, dancers, and poets have the potential to express embodied representations of how the matrix of colonial power is lived and felt differently by through technologies of anti-Black racism, settler colonialism, heteropatriarchy, sexual violence, and global capitalism. As African American poet June Jordan (2007) so eloquently enunciates, “I am not Wrong: Wrong is not my Name.” The call and response of decolonial education is to grapple with the devastating afterlife of coloniality.

Decolonial Latin American Philosophies of Education

Nathalia Jaramillo
Kennesaw State University, Kennesaw, GA, USA

Introduction

The following entry explores the historical context that has given rise to the opening for and engagement with decolonial thought. The entry specifically explores the connection between critical educational thought in the region and decolonial philosophies, to portray the favoring of the holistic approach to teaching and learning throughout the Americas and beyond.

Historical Context

Since its inception, Latin America has been characterized by waves of tumultuous conquest, independence movements, democracy building, and challenges to the historical legacy of colonization and capitalist exploitation. Of particular significance, throughout the 1970s and 1980s, a number

of countries in the Latin American region were gravely affected by campaigns of political oppression that led to dictatorships and their attendant repressive regimes. To a significant extent, the era of dictatorial regimes was a direct response to progressive social movements that sought to redistribute wealth, offer education to the dispossessed, and establish socially just principles and practices. Progressive movements threatened the survivability and growth of capitalism and economic injustice in the Latin American region and were swiftly and violently suppressed. This climate led to the exile of key educational and political thinkers and activists, such as Paulo Freire, considered one of the founding fathers of the critical pedagogical tradition in education. In exile, Freire wrote the first of many texts on the pedagogy and praxis of liberation. *Pedagogy of the Oppressed* (1970) went on to become one of the most highly read educational works throughout the world, one of the first key interventions in critical educational thought.

In *Pedagogy of the Oppressed*, Freire demonstrated the influence of a number of thinkers on his theorizing, such as Frantz Fanon, Amil Cabral, and Karl Marx. He also relied heavily on his Christian upbringing and faith in his articulation of humanity, and the values associated with teaching and learning, such as humility, lovingness, and tolerance. Freire engaged in a *dialectical* form of reasoning and proposed a transcendental form of teaching and learning that could enable students and communities to move beyond oppressive social structures and into creating socially just human relations. The basis of oppression, within a Freirean optic, was class exploitation. To move beyond the stronghold of the naturalization of poverty and the disempowerment of the poor, Freire called upon educators to recognize pedagogy as a political act, one which would create the conditions for students to acquire the critical skills needed to read the word and the world simultaneously. The movement toward fulfilling the people's collective humanity necessitated *conscientização*, consciousness raising. Freire firmly believed in a people's inherent capacity to recognize, contest, and transform oppressive social structures.

In short, Freire demonstrated that the pedagogical is political and the political is pedagogical. Though one can identify the impact that anti-colonial and decolonizing thinkers of the time had on Freire (specifically in terms of his discussion on how the oppressed identify with their oppressor), his writing on the pedagogy of freedom and liberation relied heavily on Western and Eurocentric paradigms. That is, Freire did not consider the centrality of other ways of knowing and being in the creation of another world order or in his definition of humanity. Nor did he consider the multiple forms that oppression takes. For Freire, there was oppression and there was liberation. Both were intricately connected to a class-based analysis of social hierarchies, which intentional or not did not immediately create the space for understanding and challenging interlocking forms of oppression. Freire, a revolutionary thinker and pedagogue, spoke from his geopolitical location. While his contributions have been vast, they also reflect a silence on indigenous epistemologies and rationalities that provide other pathways to create social, economic, political, intergenerational, gendered, and ecological justice. Such pathways acknowledge, but also transcend, the impact of capitalism and economic injustice on wide-scale dispossession in Latin America.

For the most marginalized groups in Latin America, namely, indigenous and Afro-descendants, oppression was indeed felt from their brute exclusion from economic wealth and justice, but it was also epistemological, racial and ethnic, gendered, and anthropocentric. The subjugation of their identities and ways of knowing did not begin with modern capitalism and the gross inequality that plagued the Latin American region; it preceded that era by hundreds of years, with the conquest and colonization of Americas. The colonization of the Americas planted the seeds for capitalism of the twenty-first century and was accompanied by a social system of differentiation that hierarchically ordered individuals and communities along multiple forms of identity (see Grosfoguel 2011).

The Decolonial Turn

Following the collapse of various dictatorial regimes in Latin America, and the beginnings of movements toward democratization, a different sociological and philosophical approach to social theory began to take root. The work of sociologists, namely, Anibal Quijano, broke away from predominantly Western and Eurocentric modes of analysis, specifically, world systems theory, which articulated the economic dependency between Latin America and the USA and its global allies. Quijano, among others, theorized economic injustice according to the multiple and overlapping systems of differentiation that accompanied global class exploitation. Termed the *coloniality of power*, Quijano articulated the centrality of race in modern Eurocentered capitalism (Quijano 2000) and traced the mental and social construction of race to the conquest and colonization of the Americas. As opposed to a class-specific analysis, the coloniality of power draws attention to the experience of colonial domination, its enduring logic, and its specific rationality, Eurocentricity. Within this theoretical optic, it is important to understand that coloniality is a model of power that is globally hegemonic (Quijano 2000).

In education, the decolonial turn was accompanied by a number of indigenous political movements that challenged the historical legacy of coloniality in education. The colonial model of education led to teaching that was highly individualistic, anthropocentric, competitive, and fragmented. Such practices reflected the cognitive dimensions of conquest, where the human is considered the king of civilization, while all that is not human is considered inferior. Within the coloniality of power, the categorization of the unhuman relied upon the systems of social stratification that accompanied conquest. That is, those whose belief systems and ways of life fell outside the Christian, European, male dominant, and humancentric paradigm were considered less than human and in dire need of salvation, civilization, and education (Mamani 2010).

Buen vivir

As a counterpoint to the colonial model of education, indigenous groups mobilized to recuperate their ways of knowing and being in education. Sumak Kawsay and Sumak Qamaña, Quechua and Aymara terms, respectively, translate into the general concept of *buen vivir* or living well. Conceptually and philosophically, *buenvivir* moves well beyond the critical tradition in education in Latin America, which relied upon the strengthening of class consciousness in the construction of collective knowledge, as discussed in the works of Freire, among others. *Buen vivir* is a decolonial and decolonizing philosophical approach to teaching and learning that offers a critique of capitalist exploitation but does so with a radical questioning outside of developmentalist paradigms. As noted by Enrique Dussel (2000), the tropes of Eurocentrism and modernity are accompanied by a developmentalist fallacy; that is, that progress and humanization begin and must progress with the traits of the modern world, which, by definition, exclude indigenous knowledge and ways of being.

Radical questioning within the indigenous traditions of *buen vivir* was made possible by a culture that lacked concepts like development or progress. *Buen vivir* ultimately strives for a post-capitalist alternative by way of two interrelated constructs. On the one hand, dialogue ushers a critique of brute capitalism and subjectivity. And on the other axis of dialogue, an emancipatory politics emerges from the ethicalmoral commitments of indigenous, nondevelopmentalist epistemology. Constructing collective knowledge through dialogue strengthens political identities and sets forward a liberatory practice based upon the rubric of living well as opposed to living better at the expense of others and nature. Thus, the vision is transcendental. In negating the logic of growth as development, individualism as freedom, and self activity as the organizing principle of change, the pedagogy of *buen vivir* prioritizes life.

The pedagogical model of *buen vivir* derives from a concept of reciprocity that precedes

capitalist formations. It was key to social organization prequest, connected to an ethical value system based on giving and receiving. Reciprocity is a sociocultural form of praxis and an ideological construction evidenced in the mantra *dar, recibir y devolver* (give, return, and give back) (Quispe 2012). Reciprocity underscores a set of practices that requires the other or others to make an equivalent response, and it is meant to be a permanent relation inclusive of all members of the community. Reciprocity is a model constructed from below and is based on territorial and educational control, self sustainable development, care of the environment, reciprocity and solidarity, and the strengthening of communal organizations, languages, and cultures. Here, educators are reminded that activism must be embedded within, and never separate itself from, the multivoiced hemispheric conversation on resistance, hope, and renewal.

As communitarian praxis, reciprocity considers woman and man not solely as a work force but principally as being with knowledge, beliefs, and thinking. Put plainly, reciprocity advances an integral subject. Notions of individual freedom, will, and choice are replaced by a holistic rendering of social life that emphasizes interdependence and interconnectedness.

Both Sumak Qamaña and Sumak Kawsay establish collective well-being as a centerpiece to social transformation. They emphasize the plurality and diversity of social life without being reduced to a philosophical relativism or groundless subject characteristic of postmodern social theory. They are also distinguished from mainstream postcolonial approaches in that coloniality is understood as an ongoing process, continuously reproduced through capitalist social relations. To speak in terms of postcolonialism does not adequately capture or recognize the multileveled and deeply engrained modalities that govern people's ways of being and interacting in a seemingly "postcolonial" social universe. In recognizing the relationship between the economic structure of society and all other forms of human sociability, indigenous epistemologies disrupt conventional

theoretical dichotomies (i.e., class struggle versus ethnic, gendered, sexual, racial, or environmental struggle) and advance a holistic rendering of social life.

As a philosophy of praxis, *buen vivir* establishes a communitarian educational experience, where learning takes place not only inside a classroom but in direct relationship with ancestral knowledge, intergenerational teachings, and a recognition that everything is connected. More specifically, that learning is connected to nature. The nature-learning connection in *buenvivir* is based upon a model of complementarity, harmony, and equilibrium. *Buen vivir* promotes a natural methodology of teaching and learning that moves beyond the modernist tropes of rationality and into an affective perception of the multiverse that surrounds communities. Put differently, *buen vivir* proposes a productive pedagogy, where teachers and students alike are encouraged to generate action, connect praxis to civil life, and recognize their origin and role in the complementarity of life (See Mamani 2010).

Buen vivir is a multilayered approach to recognize and address the entanglement of social realities. It represents a way of understanding the world as the configuration of an array of relationships, a way of life, and addresses the capacity we have to participate and alter the course of history (Macas 2010). *Buen vivir* transcends the ways that the “subject” of Western reason reproduces difference and polarities, with a focus on complementarity and the convergence of strengths between women and men. In doing so, indigenous led struggles are simultaneously acts for direct restitution from colonial capitalism and also represent efforts to contest the coloniality of power that has shaped racial, epistemic, cultural, sexual, gendered, and anthropocentric relations within the onset of capitalism as a colonizing process. Within the coloniality of power asymmetrical relations of power are recognized as both byproducts and the active constitution of a global capitalist society that began with the fifteenth-century conquest of the Americas.

Decolonial Philosophies for the Americas and Beyond

Decolonial philosophies of education in Latin America grapple with the complexity of social life and encourage educators to recognize that class exploitation is entangled with multiple forms of social differentiation. They extend the important contributions of critical educators, such as Freire, who identified and actively theorized the misery and affliction waged against the dispossessed by a global capitalist system and the internal practices within nations that continuously denied communities the opportunity to develop their full humanity. The point here is not to place decolonial philosophies in contradiction with critical pedagogies and theories but rather to bring them into conversation with one another. The critical tradition brought into central focus the impact of capitalism on people’s subjectivities and the reproductive and authoritarian models of education that serviced the needs of colonialism and capitalism. The decolonial turn highlights the overlapping and interconnected nexus of social life, one in which ways of knowing, spirituality, nature, race, ethnicity, culture, language, and gender interpolate. Decolonial philosophies in education propose new concepts grounded in a cosmovision of the totality of social life and offer a praxis predicated upon the principles of reciprocity and complementarity. They extend education into the community and nature and propose a praxis based in harmony and equilibrium with all forms of life. Taken together, educators are encouraged to recognize the entangled web of social, political, economic, historical, and cultural relations that shape educational practices. Practically speaking, educators must question the leitmotifs that organize the schooling encounter, the epistemic provisions that shape curriculum and teaching, and the social relations that inform relationships between social actors. The vision is utopic but also concrete. Through an active listening of other forms of knowledge, an understanding of the interrelationship between colonialism and capitalism, and a recognition that

the colonial legacy is enduring, teachers, students, and communities are better positioned to make learning meaningful and perhaps more importantly transformative for a just society and future. As such, decolonial philosophies are not only relevant to the indigenous groups who have struggled assiduously to recuperate their ways of knowing and transform educational praxis; they offer peoples from the Americas and beyond with an alternative conceptual register to enact pedagogies and practices predicated on an ethos of mutuality, recognition, and respect.

Decolonial Methodologies in Education

Miguel Zavala

Synonyms

Decolonial education; Decolonial methodologies; Indigenizing projects

Introduction

Rooted in a geographically specific Latin American standpoint that critically reframes colonialism and capitalism as Western/modern historical and geographical systems, the *decolonial* project is an emergent framework that not only challenges the epistemological foundations of colonialism (termed *coloniality of power*) but is a project of de-linking (Mignolo 2007) from Eurocentric thought, toward reclaiming and developing “The enunciation and expression of non-Western cosmologies and for the expression of different cultural, political and social memories” (Mignolo 2000).

For the purposes of this entry, *decolonial methodologies in education* encompasses a series of methods/strategies as they take place within education projects. Here, education is defined broadly to include both formal and nonformal educational spaces. Education is not used loosely as decolonial scholars have conflated the terms *educational* and *pedagogical* when theorizing decolonial strategies more broadly. Education is a site of struggle and rupture: It comes into being as people engage in dialogue and in response to the coloniality of power. Decolonial education has materialized throughout the world, primarily as place-based pedagogies in grass roots and institutional sites, yet the examples from Latin America discussed below have manifest at the level of the nation-State. This entry does not take into account decolonial methodologies in research and other

Decolonial Methodologies

► Decolonial Methodologies in Education

practices. While education intersects with participatory forms of research, this entry is specific to projects that are defined primarily as educational.

Finally, decolonial methodologies in education need to be repositioned and situated within broader geographic-historical processes. Specifically, a broader framework for community development and the self-determination of colonized peoples ensures that decolonial practices are defined relationally rather than by a set of essential qualities. Decolonial education is a process for community self-determination, at moments materializing in spaces of survival and at other times in the spaces of recovery. What decolonial education means and what it looks like will be defined by the particular colonialisms and sets of contradictions that make it possible. Decolonial education by and for Chicana/Chicano peoples in the United States Southwest will look different than colonized African peoples of postapartheid Africa or the *indigenous* Aymara in Bolivia. Yet, because these projects both grow in response to coloniality and deliberately seek to recover *indigenous* knowledge systems as alternatives, the struggles in these and other sites can be characterized as *decolonial* education.

The Decolonial Project

The decolonial project can be characterized as encompassing three major strategies: first, to deconstruct our very understanding of Modernity, which is traditionally conceptualized as a historically advanced expression of (Western) rationality. Decolonial thought therefore makes visible that which is concealed by Modernity, namely, the cultural logic of colonialism (and capitalism as an extension of colonialism). In their critique of Modernity, decolonial thought is marked by a different strategy than that developed by postmodernists: Modernity (and its colonial and capitalist inventions) is primarily a historical-geographical project and secondarily a discursive ordering of the world. The discourse of the Other (Dussel 1983) has served as a justification for the colonization of the Americas during the sixteenth to nineteenth centuries and formal European colonial rule

of Africa and parts of the Pacific beginning in the eighteenth century and ending with World War II. In particular, this discourse of the Other has played a dual function in settler societies: First, it served to legitimate colonial expropriation of lands and resources and the eventual deculturalization of “native” peoples by settler societies; and it helped constitute the geographic and cultural centering of Europe within an emerging global world political, cultural, economic system. A geo-historically structured epistemological project, the discourse of the Other, provided the ideological groundwork for colonial violence and expansion. This epistemological project is, nevertheless, inextricably tied to the geopolitical project of European, and later United States, world domination.

Second, the decolonial is marked by particular kind of *border thinking*, a reenvisioning from the margins. Major decolonial scholars write and theorize as intellectuals and scholar-activists from Latin America, Africa, and as First Peoples. Metaphors such as *fissures/cracks* and *rupture* signal their outsider-within as scholars but also as members of geographically marginalized communities. This kind of border thinking grows out of a decolonization of coloniality that entails not just naming the world and the colonial matrix of power that is deeply embedded in everyday life, but is also an embodied/situated praxis.

Third, the decolonial is a project for epistemological diversity. What this means is that its deconstructive moment is dialectically tied to a praxis that re-envisions and develops knowledges and knowledge systems (epistemologies) that have been silenced and colonized. Thus, the decolonial attempts to recover repressed and latent knowledges while at the same time generating new ways of seeing and being in the world. Hence, the decolonial project is strategically positioned as a struggle for an-other world beyond colonialism and capitalism.

Decolonial Methodologies/Strategies in Education

Three major methodologies or strategies in decolonial education projects include *counter/*

Decolonial Methodologies in Education,
Fig. 1 Decolonial methodologies/strategies in education

D

storytelling, healing, and reclaiming. Figure 1 below is a visual representation of these three strategies and their interlocking nature. By interlocking is meant that they interweave yet their relationship to each other is dynamic rather than linear and developmental rather than foundational. Each is dimension of the other. For example, the process of counter/storytelling in decolonial education is itself tied to the process of healing, which is also a part of the process of reclaiming.

Each strategy is defined by particular practices. Counter/storytelling involves the practices of *naming* and *remembering*. Healing involves two major practices: *social/collective* and *spiritual/psychological* healing. Reclaiming encompasses *practices, identities, and spaces*.

Counter/Storytelling

Decolonial education comes into being as people engage in dialogue and reflection (see Freirean traditions of liberatory education). This dialogue and reflection involves *naming* their social worlds. Given the fact of coloniality in everyday life, naming entails a deliberate attempt to develop

a language of critique that enables colonized peoples to understand their present situation as encircled by colonialism and its structural arrangements and cultural logics. Hence, this naming is often framed as a *counter-storytelling* that challenges the master storylines of Modernity, Eurocentrism, and coloniality. The field of critical race theory (CRT) has used *testimonio* and collective voicing as counter-storytelling methodologies. Unlike CRT which centers the lived experiences of people, decolonial education projects reposition these narratives in the context of coloniality. Further, naming is a situated practice not a rational exercise in decontextualized dialogue. Naming is mediated by dialogue, yet this dialogue is made possible by reflection upon the lived experiences of and with colonialism in all its forms. Social theory has played an important role in facilitating dialogue among decolonial scholars, yet social theory will look differently when articulated by nonacademics. At the grassroots level, naming intersects with other linguistic registers and modes that are as legitimate if not more grounded in understanding what colonialism means.

Moreover, counter/storytelling is intimately tied with particular forms of *remembering*

within/against coloniality. Colonialism is an imposition of language and knowledge systems; it is the erasure of the colonial past and subjugation of *indigenous* peoples as colonial subjects that reemerge as new liberal subjects or whose cultural histories are negated by virtue of subsuming them as “working class” by Left scholars. Drawing from *indigenous* traditions, “restorying” is a form of collective remembering that has taken place within spaces of family and community (see Cornassel 2009). This remembering is integral to reclaiming languages, spaces, and identities. Remembering as decolonizing strategy has become a powerful vehicle for *indigenous* and colonized peoples to understand not just the violence of colonialism (storytelling as “witnessing”) but to root themselves in place and where they come from. The current movement for Ethnic Studies in the United States Southwest, while contested and not unitary, includes deliberate approaches to curriculum development with the goal of understanding the present in relation to a colonial past but also to enable Chicana/Chicano students to “restory” and remember who they are as *indigenous* peoples.

Public and community arts projects have integrated naming and remembering as counter-storytelling. While not labeling the project as decolonial, the Community Arts and Cultural Development (CACD) project is an exemplar of the decolonial methodology of remembering as counter-storytelling (see Quayle et al. 2015). Drawing upon portraits of *indigenous* Aboriginal elders and through the recorded narratives that tell their stories, Aboriginal youth engaged in digital projects that brought these stories to life. The educational spaces of classrooms and public exhibits that came together to celebrate the lives of community elders were also sites of counter-storytelling, challenging settler narratives and how Aboriginal peoples have been rendered invisible in all aspects of everyday life in Australia.

Healing

A decolonial methodology in education that is often overlooked is *healing*. While naming as a

practice of counter-storytelling may be characterized as a rational, reflexive process, the practice of remembering includes aspects of healing for *indigenous* and colonized peoples. Healing involves two clearly defined practices, i.e., *social/collective healing* and *spiritual/psychological healing*. If decolonial education is a project that denounces colonialism, if it is a situated pedagogical praxis that grows out of the lived experiences of colonized peoples, then it must include a decolonization of the self in relation to community and the broader social world. Precisely, because colonialism deculturalizes people and separates them from who they are, their communities, languages, practices, and land, there is ample room and need for healing as a strategy for community self-determination.

Healing as praxis challenges dominant, Western notions of education as cognitive activity. Even in critical education traditions, such as Dewey and Freire, a general neglect of the spiritual aspects of education is manifest. Rooted in *indigenous* epistemologies, the psychological cannot be separated from the physical and all other domains. In these traditions, spiritual practices (ceremonies) have played a fundamental role in cultural learning and community (see Iseke 2013). Healing in decolonial education projects entails a particular form of recovering from the historical trauma (physical, social, cultural, psychological) experienced by colonized peoples. Healing is a (re)connectedness with each other (community) and land/Mother Earth. *indigenous* scholars have characterized healing as coming into being at the interstices of survival and development, marked by the spaces of recovery, when *indigenous* and colonized peoples come together through ceremony and education to rebuild themselves.

A clear articulation of healing in the context of decolonial education includes Villanueva's (2013) self-reflexive journey of coming to healing practices and their relevance for Chicana/Chicano-*indigenous* youth who have been detribalized and de-Indigenized. A core precept is the idea that recovery and healing be rooted in ancestral knowledges. This general precept is congruent with the broader goals of decolonial projects that

seek to restore epistemological diversity. Naming in this context includes naming one's pain, i.e., providing a language that accounts for experiences of oppression that are often internalized as self-hate and characterized by living in an imbalanced social and spiritual world. Because coloniality is so deeply rooted in peoples' lives, embodied everyday language, thinking, and bodies, people are seeking alternative knowledge systems as sources of survival, recovery, and development. The knowledge systems and ceremonial practices that have made healing central for thousands of years are becoming important sites for the envisioning and development of alternatives to capitalism and colonialism.

Reclaiming (Identities and Spaces)

Reclaiming is a strategy in decolonial education projects that involves recovering who people are (their cultural identities), their practices, and their relation to place (land, cosmos). It is a generative praxis that brings ancestral knowledges together with local, endogenous knowledges in the development of decolonial spaces. The Raza Studies program that was recently outlawed in the State of Arizona has been seminal to the emerging movement for Ethnic Studies in the United States Southwest (see Najera 2014; Rodríguez 2012). An important decolonial strategy has been the reclaiming of cultural identities. Working primarily with Chicana/Chicano-Raza-*indigenous* youth, the project, before its dismantling, was rooted in Mesoamerican knowledge systems that replace Greco-Roman and Eurocentric knowledge systems that permeate the traditional, State-sponsored curriculum.

Decolonial approaches to land-based education involve strategies that reclaim colonized peoples' relation to the land. Decolonial education in this context involves the strategy of rethinking the very concepts inherited from Western science about people and nature. Drawing from African-centered frameworks and epistemologies, for example, presents a clear challenge to the capitalist and colonialist practices that objectify/commodify natural resources and that subjugate

ecosystems to economic systems (see DiMauro and Carroll 2014). Other scholars have sought *indigenous* frameworks for rethinking global capitalism, yet what makes a decolonial education possible in this situation is more than resorting to alternative knowledge systems. Rather reclaiming is intimately tied to peoples' identities. In the process of reclaiming alternative/ancestral knowledge systems that allow colonized peoples to rethink their relation to nature and land, they are also engaged in a process of reclaiming who they are. These education strategies intersect with healing and counter/storytelling in the sense that master narratives about nature and science are challenged, while at the same time students come to decolonize their understanding of how they have been transformed as people.

Decolonial education has also emerged in projects taken up by nation-States. In Latin America, for instance, the revitalization of *indigenous* movements has led to interesting, yet contradictory struggles. While framed as socialist movements, the countries of Bolivia and Ecuador have been deliberate in rethinking formal education systems from decolonizing frameworks. Moreover, other institutions, such as the economic, legal, and political, are being rethought through the *indigenous* concept of *buen vivir* (harmonious coexistence) (see Gudynas and Acosta 2011). The fusion of modernist ideas with *indigenous* concepts has introduced a decolonial strategy for education that decenters development, capitalism, and Western ideas about nature, a valuation of nature and natural resources as life, and proposes a general anticolonial standpoint. These projects are also about the reclaiming of practices, identities, and spaces; what distinguishes them from other decolonial projects is both their grounding in decolonizing frameworks and their scale.

Decoloniality, Pedagogy, and Praxis

Catherine Walsh
Universidad Andina Simon Bolivar, Quito,
Ecuador

Introduction

Decoloniality, its pedagogy, and praxis have a history and “herstory” of more than 500 years that began in the territory to be called the Americas by the conquerors and subsequently traveled to most, if not all, corners of the world. In what follows, I endeavor to give some understanding to the social, political, epistemic, ethical and existence-based significance of these terms, and to the ongoing project they mark and construct.

On (De)Coloniality

Decoloniality necessarily evokes coloniality. Both began with the “discovery and conquest” of the Americas and the formation, with this invasion, of a model of Eurocentered global power based on capitalism, the control of labor, subjectivity, knowledge, and nature, and the use of the ideas of “race” and “gender” as mechanisms of social classification and domination. The Peruvian sociologist Anibal Quijano (2000) named this model the “coloniality of power.”

Coloniality is not the same as colonialism. While colonialism most often refers to the political and economic relation that nations have exerted over the sovereignty of other nations, coloniality denotes the long-standing and ongoing patterns of power that persist beyond colonial rule. Here the reference is not only to the patterns of power, domination, subordination, and control that continue within so-called sovereign nations themselves (what the Mexican thinker Pablo Gonzalez Casanova called “internal colonialism”). It is also, and more broadly, to the ways these patterns constitute, maintain, reproduce, and construct a world system of power.

The coloniality of power took root in the Americas (Central America, South America, and the Caribbean). It was in the particular social and historical context of this massive colonial endeavor that capitalism solidified its project of economic and of social, cultural, epistemic, ontological-existential domination. It was also here in 1492, as the Argentinian-Mexican philosopher Enrique Dussel (2000) argues that modernity as a global (and not simply intra-European) phenomenon began and the dominion of the West over the rest took hold. Latin America is crucial in this sense; a “local” history that fed and led to global designs.

Central to these designs was the establishment of a fixed, persistent, and constitutive notion of difference. This difference – hierarchical, cultural, and colonial all at the same time – played a foundational role in structuring the ideas, geopolitics, and institutions of civilization and development, of humanity and humanness, and of modernity, rationality, and knowledge. White European men

and European knowledge and historical experience came to be the epicenter of reason, authority, and power (*Eurocentrism*). Native peoples were re-named as “*indios*” or Indians, and peoples of African origin were renamed as “black,” both considered “non-human” or “less human” as compared to Europeans. Enslavement was naturalized, as was the control of labor for economic gain. The classification as “barbaric” of native languages, knowledges, spiritualities, life philosophies and visions, and millennial civilizations (conceived in harmony and coexistence with nature, territory, and the other beings of Mother Earth) became standard practice. In this scheme, the organization also began of what Maria Lugones (2010) has called the modern/colonial gender system. All of this, of course, enabled the hegemony of the West and its master paradigm and abstract “universal” of modernity and rationality, a hegemony that continues to exert power, judgment, and control over the non-Wests and Souths of the world, including the non-Wests and Souths within the Global North.

There is no modernity without coloniality, and there is no coloniality without modernity. Both are co-constitutive. Both were built on and from the racial, gendered, epistemic, and existential violence of Eurocentered conquest and colonization. For this reason, modernity/coloniality is increasingly the preferred term, expression, and analytical unit in current non-Eurocentric thought. Its use is especially associated with what has been referred to as the modernity/coloniality/decoloniality group, collective, or project (see the collection edited by Mignolo and Escobar, and especially Escobar 2010).

Decoloniality has its roots and reason in modernity/coloniality, in the struggles against coloniality (as modernity’s underside or other face), and for it otherwise. The action and project of decoloniality are, in this way, simultaneously outside coloniality and within. Decoloniality thus calls to the fore social, political, cultural, epistemological, and existence-based strategies, processes, and practices that reveal, resist, confront, and challenge the modern/colonial matrix of power. It marks and makes present struggles that work to open decolonial fissures or cracks in the

modern-colonial and capitalist-patriarchal system. Furthermore, it indicates that which occurs in the exterior and borders of this system; that is, the “otherwise” of being, thinking, knowing, and living that exists and has existed since the coloniality of power began.

Decoloniality, in this sense, is not an abstract theoretical concept or a purely academic invention. Decoloniality is signified and constructed in the collective memory and the 500+ years of lived struggles of Indigenous Nations and African-descended men and women. Similarly, the efforts, past and present, by social movements, communities, collectives, and critical intellectuals, among others and throughout the world, to defy and disengage from the logics and violences of racialization, heteropatriarchy, dehumanization, anthropocentrism, and global capitalism give decoloniality substance, meaning, and form. Decoloniality’s concept and significance are likewise made in the ongoing creation and construction of other-modes and other-practices of knowledge, thought, sentiment, being, and living. As such, decoloniality is neither a static or fixed term; its significance derives from concrete contexts and unending processes and practices of sociopolitical, epistemic, and existential struggle and creation.

Implicit or explicit references to decoloniality, its concept and practice, can be found in the work of a number of militant intellectuals, including (and from the mid-twentieth century on) Frantz Fanon and Aimé Césaire (Martinique), Sylvia Wynter (Jamaica), the Chicana feminists Gloria Anzaldúa, Chela Sandoval, Emma Pérez, Manuel Zapata Olivella (Colombia), and Fausta Reinaga (Bolivia) among others. Beginning in 2004, the concept and term came to reorient the writings, thought, and practice of the group of intellectuals associated with the modernity/coloniality project. It is in reference to the work of this group that the term is often associated today. However, the interest of this collective is not to establish or promote an authoritative (or authorized) understanding, nor is it to make decoloniality an object of study. Rather, for those associated and aligned with this work and perspective, decoloniality is an analytic tool and task. It is a political, epistemic, and

ethical option and standpoint to critically read, reveal, respond to, unsettle, act against, and intervene in the colonial matrix of power and to think from, with, and alongside racialized, genderized, and colonized subjects and struggles. This option and standpoint open up other sources, other forms, and other perspectives of knowledge, thought, and action essential in forging what some in this group refer to as the de-colonial turn.

In sum, decoloniality can best be understood as a political, epistemic, and existence-based process and project. It is not a condition to be achieved in a linear sense, nor is it an end-result. As modernity/coloniality continues to weave its web of power, decoloniality continues to put at the center of debate both the lived experience of coloniality as a constitutive component of modernity, and the initiatives, strategies, and contestatory forms that endeavor to unravel and transform the present day hegemonic forms of power, knowledge, being, and existence, and to build something else. Decoloniality is an attitude, posture, wager, and prospective way of thinking and doing, of unlearning and relearning that challenges, disrupts, transgresses, and moves beyond the logics, confines, and intertwines of modernity/coloniality, global capitalism, racism, patriarchy, heteronormativity, and the myriad of other systemic patterns of power that continue to subalternize, oppress, dominate, and exercise control and power over peoples, knowledges, land-territory, nature, worldviews, and existence, that is, over life itself.

Decolonial Pedagogy and Praxis

Decoloniality implies praxis. Similarly, it posits pedagogies, understood as methodologies, processes, and paths of struggle, practice, and praxis, that are embodied and situated; that push historical, political, ethical, and strategic learnings; and that oblige epistemic, political, ethical, and strategic ruptures and displacements, as well as recreations.

Together, pedagogy and praxis bring to the fore questions of decoloniality's "how." That is the pedagogical-praxistal questions of not only

how to rebel and resist but more crucially of how to construct, reconstruct, engender, maintain, and sustain the decolonial otherwise in struggle, practice, and life. Such questions necessarily push deeper analyses, theorizations, actions, and reflections on, with, and from struggles past, present, and yet-to-come. And they also urge consideration of our own agency and engagement, of our own thinking and doing.

The understandings of pedagogy and praxis here have their roots, at least in part, in the work, philosophy, and thought of Paulo Freire. Pedagogy, for Freire, transcends schooling and the teaching and transmission of knowledge. This Brazilian educator understood pedagogy as an essential and indispensable methodology, grounded in peoples' realities, subjectivities, histories, and struggles. Social struggles, he argued, are pedagogical settings of learning, unlearning, relearning, reflection and action. As such, the educational nature of struggle is what interested him most, along with the pedagogical practice and political praxis of individual and collective liberation.

For Freire, pedagogy and praxis are intricately intertwined. Praxis, in a Freirian sense, is an act of knowing, a dialogical movement from action to reflection, and from reflection upon action to new action. It is reflexive and not merely reflective. It is political, critical, and theoretical, and not merely pragmatic. And it is intentional and inventive; hopeful in its inquiry, acting, and doing; and continuous in movement, contention, consciousness, and formation.

Understood in this way and as an analytic perspective, sociopolitical standpoint, and pedagogical-methodological stance, praxis is what gives decoloniality movement. Said differently, praxis is the act and reflective-reflexive action that makes decoloniality a "verbality" (to use Rolando Vázquez's (2010) expression). Decolonial praxis is part and parcel of processes, practices, and actions of thinking and doing that endeavor to interrupt, transgress, and transcend the modern/colonial logic and frame, including the linear precepts, binary-based suppositions, and outcome-oriented views of Western education, knowledge, and thought. Decolonial praxis

helps give presence to relation, the relation of action-reflection-action, but also the relation of present-past. This later relation is especially important from a decolonial perspective. It refers to the inter-relationality that grounds non-Western knowledges, worldviews, and life practices and that orient a perspective, prospect, and proposition of struggle for a different model of life, living, knowing, and being in and with the world. This struggle and praxis constitute decolonial pedagogy.

Of course, decolonial praxis and decolonial pedagogy were not the specific purviews of Freire. While Freire offered much for understanding praxis as pedagogy and pedagogy as struggle, method, and praxis, his limitations from a decolonial perspective cannot be overlooked. Certainly he was a product of the post World War II Latin American Left and of Marxist and humanist emancipatory paradigms, postures, and worldviews. Although Freire began to recognize and address these limitations in his later texts (e.g., *Pedagogy of Hope* and *Pedagogy of Indignation*) and to think more critically with and from the colonial condition (and with and from Frantz Fanon), the foundation (and foundational use) of his pedagogy, methodology, and thought remained framed within the confines of Western modernity and reason (see Walsh 2015).

The problem, as the Maori anthropologist Linda Tuhiwai Smith (1999) clearly explains, is that all too frequently paradigms, postures, and views regarded as deriving from Freirian approaches negate and obscure the methodological standpoints, practices, processes, and approaches of feminist theorists of color, ethnic minorities, and indigenous peoples. Seldom do such approaches take into account the methodologies and/as pedagogies that derive from the lived experience of colonialism, racism, and the struggles for self-determination and decolonization. Similar critiques have been made of critical pedagogy.

Although Freire remains as a guide, the idea, project, and praxis of decolonial pedagogy necessarily traverse other realms, practices, and ground. Here the decolonial and pedagogical contribution of Fanon, particularly in *Black Skin, White Masks*, but also in *Wretched of the Earth* is key, most especially for its analysis of dehumanization and

its formation of a praxis of liberation and a decolonizing pedagogy for humanity. In her powerful book *Pedagogies of Crossing*, the Caribbean feminist M. Jacqui Alexander (2005) engages the material and psychic fragmentation and dismemberment produced by colonization. Her pedagogies and practice of “pedagogization” cross the inherited divides of sacred and secular, embodied and disembodied, as they fashion and configure new ways of being, of knowing, and of wholeness. Certainly Alexander and Fanon are not alone in giving credence, substance, and force to decolonizing pedagogical thought and practice. Yet the crucial difference that they (and other decolonial thinkers) mark is in the place of enunciation. Thinking from and with the lived experience of the colonial wound and its matrix of power, marks a specificity of perspective – a decolonial perspective – noticeably absent in Freire and many of his followers.

In Latin America, as in other regions of the “Souths” of the globe, decolonial pedagogies are rising. The emergence and presence of what some community-based and militant intellectuals call pedagogies of resistance and reexistence, signal affirmation, hope, and life in the midst of conditions of negation, violence, death, destruction, and despair (see the collective text edited and compiled by Walsh and published in 2016, as well as the earlier volume published in 2013). In a region (not unlike others) where the war of capitalism, the politics of extractivism, and the reorganization of modernity/coloniality/heteropatriarchy are in full swing, the struggles for an otherwise of being, thinking, and living are about life itself. It is this struggle of and for life that guides and gives substance, reason, and force to decoloniality as pedagogy and praxis.

The fact that pedagogies and/of praxis happen and are fashioned, shaped, and built mostly outside the formal institution of education is significant; lest we forget the central role of the institution of education in the development, maintenance, and reproduction of the modern/colonial matrix of power. For this very reason, schools and universities are necessary sites of decolonial pedagogy and praxis as well. They are the sites where many of us struggle day-to-day to transgress, disrupt, and displace modern/

colonial logics, rationalities, and world-visions as the only possibilities of humanity, humanness, existence, knowledge, and thought. They are the sites, but not the only sites of course, where the doing of decoloniality, pedagogy, and praxis need to happen.

Decolonization and Higher Education

Sharon Stein and Vanessa de Oliveira Andreotti
University of British Columbia, Vancouver, BC,
Canada

Introduction

Given the central role of universities in social reproduction, and in the creation and legitimization of knowledge, decolonization and its place in higher education are a subject of significant

interest in both social movements and scholarly critique across the globe. Decolonization can be broadly understood as an umbrella term for diverse efforts to resist the distinct but intertwined processes of colonization and racialization, to enact transformation and redress in reference to the historical and ongoing effects of these processes, and to create and keep alive modes of knowing, being, and relating that these processes seek to eradicate. Colonization and racialization have both material and epistemic dimensions, which together shape social relations and enshrine categories that are then used to justify: occupation of Indigenous land; expropriation and expendability of Black life; the binary, heteropatriarchal gender system; claims about the universality of modern Western reason; objectification and exploitation of “nature”; capitalist property relations and modes of production; militarism; possessive individualism; and the very concept of race.

Under the broad umbrella of decolonization, there exist a number of paradoxes, disagreements, and diverse visions for decolonial futures and possible means of arriving at these different futures. These competing visions may even be held by a single individual. As well, there is significant discussion around whether decolonization projects overlap with, are reducible to, or are incommensurable with other justice projects. Thus, any effort to address decolonization and higher education necessarily contends with diverse understandings of “decolonization” itself. This entry reviews the general contours of decolonization and explores contrasting assumptions, desires, and concerns that orient different interpretations of decolonization in the current context of higher education.

Decolonization Efforts and Demands

There is no single genealogy of decolonization, particularly as racial and colonial violence have been resisted since the fifteenth century when Europe first initiated its modern project of global domination and dispossession through Black enslavement and Indigenous colonization. However, many trace the term decolonization to the mid-twentieth-century anticolonial movements in

Africa and Asia that sought to dismantle European colonial rule, as well as Indigenous self-determination and antiracist social movements in European and settler colonial nations during the 1960s and 1970s. While decolonization efforts have been punctuated by several notable moments or eras, it may also be understood as a set of diverse, ongoing processes, rather than a distinct event or set of events.

Today, varied demands for decolonization may be summarized in three primary concerns: (1) the continued colonization of Indigenous peoples in settler colonial countries, as well as the ongoing legacies of Black enslavement, and the violent policing of national borders; (2) the highly uneven accumulated social, economic, and epistemic effects of centuries of colonialism and slavery for populations throughout the globe; and (3) the continued colonial architectures of global governance, such as the loan policies of the IMF and World Bank, strict immigration control in Europe, and the ongoing assertion of Western nations' right to police the world (militarily and otherwise), all of which favor the maintenance of Western dominance and extend the reaches of global capitalism.

Collectively these and other decolonizing critiques signal recognition of the continuation of a "Modern/Colonial Capitalist/Patriarchal Western-centric/Christian-centric World-System" (Grosfoguel 2012, p. 82) and point to the need for decolonization to be a global project, even as it manifests across time and place in distinct ways. For instance, a significant development around decolonization and higher education in Latin America has been the growth in State-sponsored and autonomous intercultural universities that emphasize Indigenous epistemologies and the importance of horizontal engagements in collaboration with local communities. However, this entry emphasizes decolonization and higher education in the US and Canadian context.

Historicizing Decolonization and Higher Education

Scholars have identified many ways in which modern universities, from their very beginnings,

were complicit in and benefited from colonization and racialization. The expropriation of Indigenous lands was and remains a necessary condition of possibility for US and Canadian institutions of higher education, and many early institutions forced slaves to labor in their construction and/or were founded and funded through wealth accumulated through slavery and colonialism (Wilder 2013). Many Western institutions were also deeply involved in the colonial cataloguing of non-Western knowledges and the production of knowledge in support of scientific racism and other racialized and colonial classifications used to justify forcible assimilation, military occupation, and even annihilation of nonwhite populations (Said 1978; Smith 2012). As a result, some have suggested that the emergence and eventual dominance of the modern, Western, secularized, and supposedly universal episteme (mode of knowledge) was only made possible in the context of Europe's projects of conquest and enslavement (Spivak 1988; Wynter 2003).

A constitutive paradox of the colonial construction of knowledge therefore haunts any effort to decolonize existing institutions: claims about the universality of Western knowledge can only be sustained in contrast to the particularity and partiality of non-Western knowledges. Today higher education institutions continue to reproduce an epistemological hierarchy wherein Western knowledges are presumed to be universally relevant and valuable, while non-Western knowledges are either patronizingly celebrated as "local culture," commodified or appropriated for Western gain, or else not recognized as knowledge at all. Curricula remain dominated by Western epistemologies, especially Western sciences and technologies, and research in these areas also tends to be the most heavily rewarded through grants and other forms of institutional support and validation.

Western epistemological dominance occurs not only in colleges and universities within the West itself but also in the non-West, where Western institutions are often viewed as the model for the ideal university (Nandy 2000). This has led many to emphasize the importance of "decolonizing the mind" (Thiong'o 1986) and the pursuit of cognitive justice in higher education

research and curricula (Sousa Santos 2007). Others note the potential danger of emphasizing the epistemic dimensions of decolonization at the expense of more material struggles over land and other restitutions (Tuck and Yang 2012). However, these are not mutually exclusive, and demands for decolonization from both of these perspectives and more are increasingly being articulated by students, faculty, and activists around the globe in both Western and Westernized universities, within former imperial metropolises, settler colonial nations, and formerly colonized countries.

These recent efforts cannot be delinked from earlier movements in the 1950s that led to the desegregation of historically white institutions and later student movements in the 1960s and 1970s that demanded more wholesale institutional transformation through the de-Westernization of curricula and knowledge production and more significant redistribution of material resources. Specifically, these movements contested the framing of racialized and Indigenous peoples as objects of knowledge and sought institutional recognition and support of themselves as subjects of knowledge. Such movements did not have all their demands met, but in many cases achieved the institutionalization of ethnic and women's studies programs, as well as the creation of student cultural centers and culturally specific programming on campuses (Ferguson 2012). Around the same time, Indigenous controlled colleges and universities were founded in the USA and Canada.

However, today many of these departments, programs, and institutions struggle to receive adequate funding. In fact, more recent demands for decolonization have come from a growing dissatisfaction with what are understood to be weak, tokenistic, and conditional commitments to the inclusion of nonwhite/Western perspectives, peoples, and modes of knowledge production in historically white and otherwise white-dominated mainstream institutions (Ahmed 2012; Nandy 2000). There is further frustration with the fact that nonwhite students and faculty continue to be underrepresented in higher education, particularly in the most prestigious positions and institutions.

This dissatisfaction has also been fed by the increasing privatization of public higher education, the weakening of affirmative action commitments, and the institutional cooptation of the very demands that were made decades earlier for radical transformation.

Decolonial Possibilities in Higher Education Today

In the current conjuncture, many questions have arisen around the possibilities for institutional transformation, as well as around the desired horizon of change. In this, there is significant tension around the purportedly universal nature of institutions like colleges and universities and the demand for inclusion within them by those that are consistently deemed categorically particular, such that their inclusion remains conditional and premised on degrees of difference in reference to a universal standard. In response, some have advocated for the need to reimagine the *uni*-versity as a *pluri*-versity (Boidin et al. 2012).

More generally, questions have arisen around to what extent it is possible to decolonize institutions that are supported by the nation-State and capital and/or whether these institutions can serve as spaces in which decolonization projects are imagined and enacted. For instance, if universities were created and adapted to support a colonial order of knowledge and tend to reproduce our existing social system, to what extent can these institutions be transformed without larger social transformations? What approaches to knowledge might neither reproduce the colonial order of knowledge nor contest it using colonial terms? Is it even possible or desirable to produce alternative knowledges within existing educational institutions, given that they would likely be unintelligible according to existing modes of knowledge production?

The remainder of this entry reviews responses to these and other questions around decolonization and higher education by offering a summary of three different critical approaches to colonial and racial violence in the context of contemporary

colleges and universities; not included are those who do not recognize this violence as a problem.

Three Sets of Responses

The first category of responses emphasizes individual and institutional interventions focusing on proportional representation, advocating primarily for increased numbers of Indigenous, racialized, and low-income students and faculty, and the supplementation of existing curricula with non-Western perspectives. Rather than decolonization, the goal is enhanced diversity, which manifests as selective recognition and inclusion of difference into existing institutions in ways that do not significantly challenge existing measures of success or structures of power. Within this position, the problems of racism and colonialism are identified largely at the individual level. Thus, emphasis is on addressing the ignorance or bias of individuals from dominant groups through more knowledge or the right institutional policies. Meanwhile, for individuals from marginalized groups, emphasis is on enhancing their capacity and social capital so as to better prepare them to successfully compete for mobility within the existing system. Due to the lack of structural analysis, the uneven distribution of power, wealth, and opportunity across race is not problematized. As a result, there is no redistributive impulse, and the desirability of social relations premised on competition for scarce resources goes unquestioned. Further, inclusion is often framed as a benevolent gift, such that nonwhite individuals are expected to perform their gratitude and refrain from further dissent. More radical demands or critiques may be dismissed as ungrateful, unproductive, or uncivil. Thus, the boundaries of the institution and of acceptable modes of knowledge production and critique are still firmly policed by white and capitalist power structures. The majority of institutional actions around colonialism and race fall within this category.

The next set of responses focuses on systemic analyses of the creation of inequalities and is

characterized by its recognition of epistemological hegemony within higher education. These analyses emphasize the ways that the harms of racialization and colonization are enacted through institutional structures and logics that consistently reproduce existing racial and economic hierarchies, distribute resources in highly uneven ways, and exploitatively extract labor and symbolic resources from marginalized groups to accumulate wealth for those in power. Critiques from this perspective tend to emphasize one or perhaps two dimensions of social violence, such as capitalism, racism, patriarchy, heteronormativity, nationalism, or colonialism, but may not link them all together. Demands for significant institutional transformation are focused on the redistribution of material and epistemic resources and the centering and empowering oppressed students and faculty. Significant demands are also made for institutional redress for historical and ongoing participation in violence, for instance, demands to rename buildings named after slave-owning alumni, divest from fossil fuel or prison companies, or grant free tuition to Black and Indigenous students. Approaches to change in this category may be framed as “speaking truth to power” through critique as well as direct action and/or may enact a principled refusal to engage. Efforts in this vein have historically led to significant institutional transformation, including *de jure* desegregation and the establishment of ethnic studies departments, even as institutional cooptation consistently threatens to undermine the radicalism of the demands. Responses in this category may also reproduce at least some parts of the system they critique, as it is difficult to disrupt all colonial elements at once, particularly if there is a desire to remain intelligible so as to have one’s demands heard by those in power.

The final set of responses emphasize the ontological hegemony that structures and orients the existing university and identify the fundamentally violent and unsustainable system within which it is embedded. These approaches suggest that modern existence is dependent on colonization and racialization for its continuation, and therefore consider the limits of the kinds of transformations

that are possible within higher education “as we know it,” especially as long as it is funded and regulated by the nation-State and capital. Because current crises of the university are linked to the *longue durée* of modernity and its racial and colonial conditions of possibility, ultimately it is thought that reform is not possible and what is needed is to imagine and create radically different, unknown futures for higher education and beyond. Thus, for example, this position critiques the fact that expanded access to higher education is conditional on a willingness to adhere to existing institutional norms but also points out that expanding access to a harmful (capitalist) system does not necessarily make that system any less harmful. From here there are different emphases as to what should be done in the short term, including hacking the university, i.e., appropriating its resources for use in radical projects; experimenting with alternative modes of organizing education, for instance, the creation of autonomous “eco-versities”; or “hospicing” the university by learning from past mistakes and preparing for the transition into different decolonial futures. This position emphasizes the double binds and contradictory complicities that result from conflicting desires for decolonization *and* for fulfillment of the promises that colonial system offers. Further this position also recognizes the need for immediate harm reduction efforts within higher education, including those outlined by the other two positions, though in general these are thought to address the symptoms rather than the root causes of harm and thus are not understood to be the final horizon of decolonial possibility. This is illustrated in the following quote:

[T]here is no way we are going to intellectually reason our way out of coloniality, in any conventional academic sense. There is no way we are going to publish our way out of modernity. There is no way we are going to read our way out of epistemological hegemony. (Burman 2012, p. 117)

While often these three approaches are theorized as distinct and potentially incommensurable, in practice people tend to strategically and incoherently make use of different approaches, often at the same time, depending on what is possible

and desirable within any given situation. Enacting decolonization in the context of existing higher education institutions is an ongoing, challenging, messy, and often contradictory process.

Conclusion

Decolonization is often evoked as an event of interruption of a specific process or characteristic deemed “colonial” and therefore undesirable. However, this conceptualization is grounded on a very selective analysis of coloniality and colonization. An alternative mobilization of decolonization in education, taking account of the force, pervasiveness, and complexity of colonial perceptions and relations, would frame decolonization as a lifelong, life-wide process, fraught with difficulties, competing demands, and uncertain outcomes. As part of this process, higher education may be one of the many spaces in which to denaturalize the modern/colonial world, reach the limits of what is possible within it, and experiment with the apparently impossible, without assuming that such work can ever be free from complicity in colonial harm.

Decolonizing Knowledge Production

Sandew Hira

International Institute for Scientific Research,
The Hague, Holland

The Decolonial Movement

Around the globe today, there are countless groups that raise the banner of decolonizing knowledge, power, and the mind. Books, articles, conferences, summer school programs, research

projects, websites, Facebook groups, and international networks have been formed under the flag of “decolonization.” It has become a catchphrase in new social movements around the world and in the academia. “Decolonizing knowledge and power,” “decolonizing the mind,” “decolonizing the city,” “decolonizing the diet,” “decolonizing architecture,” “decolonizing knowledge production,” and many more expressions that begin with “decolonizing . . .” are part of a broader movement that aims to contest the continued influence of colonialism on knowledge, understanding, and contemporary society.

Across the academia decolonizing knowledge has challenged colonial ideas labeled as racism, postcolonialism, or Orientalism and has advanced frameworks such as critical race studies, postcolonial studies, and decolonizing the mind. Departments like African-American Studies, Asian and Asian-American Studies, Chicano/a Studies, and Native American Studies are at the vanguard of such analysis. Outside the academia, in community groups and social movements, decolonizing knowledge can be traced to resistance against colonialism from the very start in 1492.

The central premise of the decolonial movement is the idea that there is a third narrative of liberation of mankind besides Liberalism and Marxism: a decolonial narrative.

Liberalism grew out of Western Enlightenment with the narrative of the liberation of the mind from the authority of the church and the liberation of the individual from the constraint of society. Marxism is an offshoot of Western Enlightenment that offered a critique of Liberalism from a class perspective. In the anti-colonial movements of the Third World, Marxism was adopted as a narrative of liberation. The decolonial movement tries to articulate a philosophy of liberation outside the framework of Western Enlightenment.

The decolonial movement arose in a complex set of circumstances in the late twentieth century. This entry goes into with five factors explaining the rise of this movement and the creation of decolonial knowledge.

The decolonial knowledge production covers many themes, from decolonizing mathematics

and physics to epistemology, history of science, and basis categories in the social science. This entry is limited to epistemology, the concept of class and a theory of racism, and knowledge production.

The Rise of the Decolonial Movement

Several factors explain the rise of the decolonial movement in recent decades.

The first factor is the collapse of the socialist bloc and the accompanying demise of Marxism. Within 3 years – between 1989 and 1992 – 20 of the 24 countries dissolved their socialist system including the first socialist country, the USSR. In the remaining four countries – China, Vietnam, Cuba, and Laos – ongoing experiments seek to combine central planning with some kind of modified market economy. The downfall of the socialist bloc contributed to the downfall of Marxism as a discourse of liberation (Kramer 2012).

The second is the fall of the West and the rise of the rest (Zakaria 2009). Colonized countries in Africa, Asia, the Middle East, Latin America, and the Caribbean are rising as regional and global power: economically, politically, and militarily. Their rise strengthens their self-confidence culturally and opens up a space for probing other paths of knowledge production that goes against Western cultural hegemony. A remarkable case is China. During the *Great Proletarian Cultural Revolution* (1966–1976), the ancient Chinese philosopher Confucius (551–479 BCE) was denounced by Mao Zedong as reflecting a semi-feudal culture. He criticized those who advocated the study of Confucius, for promoting backward ideas. In 2014 President Xi Jinping praised Confucius and the ancient Chinese philosophers for their rational thinking and cultural achievements of China and currently looks to them as a source of ideas for running China (Xi Jinping 2015).

The third is the struggle of social movements for dignity and recognition based on ancient civilizations. In large parts of the Americas, the indigenous population has been largely wiped out by colonial genocide. But some countries still have sizable communities left, including

Peru (45%), Bolivia (44%), Guatemala (41%), Mexico (28%), Belize (17%), Ecuador (14%), and Panama (12%). Five hundred years of colonialism did not crush their spirit. In 2005, Evo Morales was chosen as the first indigenous president in a general election in Bolivia. In 2009 a new constitution was adopted in a referendum with 91% attendance and 61% approval. The preamble opens with a statement of acknowledgment of the ancient history of its people and defines as one of the functions of the State as to construct a just and harmonious society built on decolonization (see Bolivia 2014).

The fourth factor has to do with the rise of social movements in multicultural societies across the West. Communities of color in Western Europe and North America continued the struggle to establish, defend, and sustain their identity in the face of a hegemonic Western culture. Their encounter with racism has forced them to seek narratives of liberation that affirm their identity, including narratives outside of Marxism that use class as the basic unit of social and political analysis. In France decolonial activists have even invented the term “white left” to insist that racism is also virulent in the socialist movement that have expressed support for banning the veil (Bouteldja 2014).

The fifth determinant is the unfinished business of the classical liberation movements. In South Africa the promise of a rainbow nation that would overcome the legacy of apartheid has fallen short. The disappointment with the transformation to a new society has led black South Africans to question the old narrative of liberation and search for a new one. In 2015 students from the University of Cape Town mobilized so that the statue of Cecil Rhodes, a leading colonialist and advocate of apartheid, must be brought down. In 2002 the Rhodes Trust and President Nelson Mandela formed the Mandela Rhodes Foundation with an endowment of £10 million to provide scholarships to train a new generation of future African leaders. It was an attempt to reconcile a troublesome past. The “Rhodes Must Fall” movement spread to other parts of South Africa and carried the slogan of decolonizing the university. It was also a critique of the attempt to reconcile Rhodes with the new future of South Africa (Mandela 2003, UCT RMF 2015).

Some Themes of Decolonial Knowledge Production

There is a wide variety of themes in decolonial knowledge production. Some are related to the specific factors behind the rise of the decolonial movement. The decline of socialism and Marxism brought to the fore the relevance of the concept of class. The rise of China as a superpower comes with a reappraisal of knowledge produced by ancient Chinese philosophers. The social movements in Latin America that is based on ancient indigenous civilizations brought competing concepts of the relationship between nature and society in the field of sustainable development. The social movements in the multicultural societies in the West brought the question of race to prominence in debates about identity formation of the West. In South Africa the failure of the ANC to realize the dreams of social justice and prosperity opened new debates on race relations in Africa.

Here are a few examples of themes that are developed in the decolonial movement.

Epistemology

Western science was based on the idea of René Descartes “I think, therefore I am.” A decolonial critique centers on five aspects.

First, there is the question of the location from which you speak. Imagine an enslaved African running from his enslavers who will torture him if they catch him. If there would be anyone in the world to doubt his existence, then it would be this man running for his life in a reality that looks like a horror dream. Yet, the idea that during his flight he might consider philosophizing about the concept “I think therefore I am” would sound like a sketch from a stand-up comedy. So if you situate the discussion not in the house of Descartes in The Hague where he sits at his warm fireplace with a wine in his hand, but, in the Caribbean during slavery, the nonsense becomes apparent (Descartes 2002, p. 7).

Second, Western philosophy looks at knowledge production as the result of an individual activity of thinking. If we were to do that consistently, we could not ever know if we are dreaming, because if you were the only person in the world,

there would be nobody to tell you if you are awake or if you are dreaming. That knowledge cannot come from you. Somebody else has to tell you that. It is impossible to say “I think, therefore I am not dreaming.” You can also think in your dream, as we know from experience and common sense. African scholars present the alternative concept of Ubuntu that argues that knowledge production is realized through communities. They paraphrase Descartes in the slogan “I am because we are.” Knowledge is not only acquired by an individual that conducts research, but is transmitted via social relations from generation to generation and is ingrained in the collective mind of a community. An individual does not need to go through the process of accumulating knowledge (Gade 2012).

Third, even in his dream, Descartes separates object from subject. His imagination is so limited that can only think of the subject that is dreaming. What about the object that is dreaming? In Chinese philosophy there is a famous tale about the Taoist philosopher, Zhuang Zhou (369–286 BCE), that goes as follows. Once, Zhuang Zhou dreamed he was a butterfly, a butterfly flitting and fluttering about, happy with himself, and doing as he pleased. He did not know that he was Zhuang Zhou. Suddenly he woke up and there he was, solid and unmistakable Zhuang Zhou. But he did not know if he was Zhuang Zhou who had dreamt he was a butterfly or a butterfly dreaming that he was Zhuang Zhou. Descartes’ imagination was limited in his conceptualization of life, which was limited to human life (Lee 2015).

Fourth, there is something fundamentally wrong with the concept of doubt and common sense in Descartes. No sane person doubts his or her existence. You can have doubts about the absurdity of life – am I really going through this experience – but it is impossible to doubt your existence. Because no one can image his “nonexistence.” You can imagine not being at a certain location, but what does it mean to say “I don’t exist?” There are many human needs and actions that assure your existence, not only the process of thinking, but any other human activity. It is matter of common sense. If you doubt your existence, put your hand in a fire, let yourself experience hyperbolic doubt, and that will bring common sense

into you. Or starve yourself to death and see how long it takes to come to the conclusion “I am hungry, therefore I am.” There is a saying in Indian philosophy that distinguishes between common sense and nonsense: “we can mistake a rope for a snake, but we don’t mistake a snake for an elephant.”

Classes and Oppressed Groups

Marxist analysis is based on the concepts of class and the ownership of the means of production. A class is defined by its relationship to the ownership of means of production and the control of labor power (Marx and Engels 1847, pp. 14–15). Decolonial thinkers question the Marxist concept of class as a central tool in analyzing social relations.

Italian Marxist Antonio Gramsci shifted this notion by introducing the rather vague concept of the “subaltern,” which he defines as groups of people who are subjected to the initiatives of the dominant class, even when they rebel. Peasants, who own the means of production (land), also belong to the subaltern groups (Gramsci 1999, pp. 202–203). The concept was taken up by South Asian historians in the Subaltern Studies Group who articulated new narratives of the colonial history of India and South Asia on the basis of this concept (Guha 1982).

Aimé Césaire introduced the concept of race and the colonial subject into the Marxist discussion on class in his letter of resignation from the French Communist Party in 1956: “It is clear that our struggle – the struggle of colonial peoples against colonialism, the struggle of peoples of color against racism – is more complex, or better yet, of a completely different nature than the fight of the French worker against French capitalism, and it cannot in any way be considered a part, a fragment, of that struggle” (Césaire 1956).

Marcus Garvey elaborated on the concept of race and explained the struggle in the world as a struggle of white Europeans seeking to dominate black people and people of color across the world. His narrative resonated in North America, the Caribbean, and Africa, and he succeeded at that time in building the largest black organization in the world (Universal Negro Improvement

Association) with up to one million members. Race thus became a central concept in decolonial thinking. It laid the foundation of Pan-Africanism as a movement to unite all people of African descent against colonialism.

Outside the Afro experience, similar narratives were developed based more on culture than race. In academia Edward Said used the concept of Orientalism to characterize Western attitude of superiority toward Eastern cultures that they regarded as inferior (Said 1977). The response to Orientalism was the rise of Pan-Islamist movements in the nineteenth century that sought to unite Muslims to resist colonial occupation of Muslim lands. The Pan-Islamists took Islam as the basis for organization (Sever 2010). Pan-Arabism in the twentieth century sought to organize colonized people in North Africa and West Asia on the basis of Arab culture (Lungu and Gokcel 2014). Pan-Asianism was a movement that aimed at uniting all Asian people against colonialism (Duara 2001). The decolonial narrative did not take class but the colonial subject as the central unit of its analysis.

There is a complex relationship between the factors determining social relations such as class, race, ethnicity, gender, and nation. Decolonial analysis brings in the way colonialism has impacted these factors in such a way that ethnicity became a core factor in the global colonial system.

Theory of Racism

As race and ethnicity play a crucial role in the decolonial analysis, a theory of racism is a crucial part of decolonial thinking. A decolonial theory of racism as developed by Ramon Grosfoguel (Grosfoguel 2013) and the author (Hira 2015) has two dimensions. One dimension tackles the ways in which racism is embedded in knowledge production. The other confronts the ways in which racism is embedded in society in general.

In knowledge production racism is defined as a concept that articulates that superiority/inferiority of social groups is related to characteristics such as soul, biology, and culture. The articulation of racism is intertwined with the authority of knowledge production. Ramon Grosfoguel (Grosfoguel 2013, pp. 81–83) explains that there are three

forms to this articulation of racism in knowledge production. The first form is the articulation of superiority/inferiority in terms of creatures having a soul. In the debate of Valladolid of 1550 between theologians Batolomé de Las Casas and Juan Jinés de Sepúlveda, the first argued that the indigenous people of the Americas had a soul, and therefore they were humans – although like children – while the latter sustained that they had no soul, and therefore they were animals that could be sold. The authority of knowledge production was Christian theology. This is called theological racism in knowledge production and was developed between 1492 and 1650 when the Spaniards colonized the Americas.

The second form is the articulation of superiority/inferiority in terms of biological characteristics. Between 1650 and 1850, superiority/inferiority was articulated in terms of biological traits (Hira 2015, pp. 138–140). Africans (and their descendants) – who previously were regarded as civilized Moors in Europe – were now seen as cattle that could be traded in the era of the transatlantic slave trade. The authorities of knowledge production were philosophers and natural scientists, the founders of science in Europe. This is what we called biological racism.

The third form is the articulation of superiority/inferiority in terms of culture and social formations. Some cultures and social formations are viewed as backward. Western society and culture is regarded as the highest stage in the evolution of human civilization. The authority of knowledge production is the rising social sciences from the second half of the nineteenth century. This is called cultural racism (Grosfoguel 2010, p. 38).

The second dimension in the theory of racism is related to how racism is embedded in the economic, social, political, and cultural institutions of society. The concept of institutional racism is used to explain that racism is not about the interaction between human beings that is deformed by feelings of superiority and inferiority but about institutions that promote and maintain the relationship of superiority/inferiority based on theology, biology, or culture. This approach rejects the simplistic and narrow notion that racism is simply the

prejudice of individuals, instead focuses on the institutional ramparts of racialization, including laws, organizational operations, religion, and ideologies of individual freedom.

The Perspective for Decolonizing Knowledge Production

There are many themes that have been explored by decolonial thinkers around the world, among them mental slavery and decolonizing the mind, feminism, decolonizing mathematics and the natural sciences, the need for a decolonial terminology, and new concepts of world history.

Within these themes the initial approach centered on the nature and extent of bias in Western knowledge production, including its rejection of and hostility to knowledge production in non-Western civilizations. Currently the prevailing tendency seeks to develop alternatives to Western knowledge production: the production of concepts and theories that are based on a critique of Western knowledge production and on contributions by ancient civilizations. Islamic and Buddhist economic theories are being developed based on different moral values in competition to economic theories of the West that are based on profit maximization which has greed as its moral base (Baqir as-Sadr 1994 and 1982, Prayukvong 2005). Indian mathematician C.J. Raju – who works on decolonizing mathematics – criticizes the metaphysical foundation of Western mathematics and proposes to return to Indian mathematicians that based their work on an empirical foundation (Raju 2007).

The five factors behind the rise of the decolonial movement in recent decades as explained above indicate that decolonizing knowledge production is not a new trend that will disappear and be replaced by a new trend. Since the five factors are results of deeply embedded patterns of colonial knowledge production, it is hard to see them as trendy discourses that will, as time goes by, be replaced with other ones. Therefore, they will continue to push the need for decolonizing knowledge production. They will continue to develop new basic categories

and concepts in the different disciplines of science both as a critique of Western categories and concepts and as an alternative to Western knowledge production.

Organizations

Decolonial Universities

There are a few universities in the world that take on “decolonization of knowledge” or decolonization in general as a central task. Bolivian universities are an example. Bolivia is the only country where the concept of decolonizing society is enshrined in the constitution. The 2009 constitution defines one of the functions of the State: “To construct a just and harmonious society, built on decolonization, without discrimination or exploitation, with full social justice, in order to strengthen the Pluri-National identities.” It also defines the purpose of institutes for higher education: “Education is unitary, public, universal, democratic, participatory, communitarian, decolonizing and of quality.” (Bolivia 2009)

The government has established three universities named after indigenous leader of the resistance against colonialism: Tupac Katari, Apiaguaiki Tupa, and Casimiro Huanca. The universities are Tupac Katari Aymara University, Apiaguaiki Tupa Guarani University, and Casimiro Huanca Quechua University. They provide a decolonial curriculum in higher education. The description of one subject in a curriculum (agronomic technique) explains that the curriculum aims to train professionals to implement business ventures under the community and family model. Science and technology should be put at the service of communal own (not State-owned) companies. In organizational terms, the university is structured under the community democracy, which means that the decision is exercised by the community through collective deliberation and constitutes the highest authority and power, which is contrary to the elitist form of a decision as it happens in the liberal way. University officials are not elected through party competition or composition of fronts but directly through rotation and shift system (Universidad 2008).

In 1991 Canada established a Royal Commission on Aboriginal Peoples to address the struggle of the indigenous people (called First Nation in Canada). In 1996 the commission presented a 4,000-page report: The commission acknowledged the destructive and Western legacy on the First Nation people and the need to decolonize the universities. It came up with 440 recommendations, among them the establishment of an aboriginal people’s university. In 2003 the First Nations University of Canada was opened. It is embedded in the experiences of the First Nation communities and has an annual enrollment of 3,000 students. They base their university on collective values of wisdom, respect, humility, sharing, harmony, beauty, strength, and spirituality. The students learn in the context of their own traditions, languages, and values and in an environment of First Nation cultures and values that recognizes the spiritual power of knowledge (First Nation 2003).

Networks

The production of decolonial knowledge is achieved inside and outside academia. Inside academia there are individual researchers and research centers conducting research. There are academic networks that aim to unite researchers on specific subjects. One example is the Third World Approaches to International Law (TWAIL) that originated from a group of Harvard Law School graduate students in 1996. They study the mechanisms of how international law perpetuates the subordination of non-Europeans to Europeans through international legal norms and propose alternative mechanism of international law. They organize conferences on a regular basis to share and further develop this knowledge. Other networks exist outside TWAIL on international politics such as the Colonial/Postcolonial/Decolonial Working Group which is sponsored by the British International Studies Association. There are also regional networks that organize activists and thinkers on a regional basis. For example, in Africa there is the Africa Decolonial Research Network based at the University of South Africa. The Alaska Native Knowledge Network compiles information about knowledge systems among Alaska natives. Decoloniality Europe

is a network of knowledge institutions, activists, and human rights organizations.

There are international networks such as *Multiversity* based in Malaysia that organizes biannual conferences that brings together scholars and activists from around the world to work on decolonizing the educational system.

Journals

Many journals devote articles on decolonizing knowledge production. Here are two examples of journals devoted to this subject. For example, *AlterNative: An International Journal of Indigenous Peoples* was launched in 2005 by New Zealand's Māori Centre of Research Excellence based at the University of Auckland in Aotearoa New Zealand. It presents scholarly research on Indigenous worldviews and experiences of decolonization from Indigenous perspectives from around the world.

Another journal along the similar vein is "Bandung: Journal of the Global South," which is published by the Springer, and it is considered a cross-disciplinary human and social sciences. It aims at developing new theoretical perspectives that should be grounded on the complex post-colonial landscapes of the African, Asian, and Latin-American peoples, for identifying their own ways and strategies of development and decolonization.

Deconstruction

► Derrida and the Ethics of Reading

Deconstruction, Philosophy, Education

Peter Pericles Trifonas

Curriculum, Teaching, and Learning, Ontario
Institute for Studies in Education/University of
Toronto, OISE/UT, Toronto, ON, Canada

How is it possible to untangle, demystify, and transgress the limits and limitations of the aporia of the death of philosophy and resolve the question of its question, and of its right, and of its institution, as well as who has the right and responsibility to respond to it. Three points are worth further elaboration:

1. The first concerns the post-metaphysical horizons of community, both public and academic. It is not a simple matter of *fighting*

against the pronouncement of the death of philosophy, even though it may be a premature burial. Or so we would like to, and have to, think. To try to resist what is posed as the end of metaphysics by mounting arguments against the finality of this perspective in the tradition of a “critique” or negative determination that seeks its own affirmation through the violence of opposition is a wasted effort. “A philosopher is always someone for whom philosophy is not given, someone who in essence must question himself or herself about the essence and destination of philosophy (Derrida 1994).” Which is to say that the alterity of metaphysics as well as the power of its teleology is always close at hand, whether or not a transcendence of its logic *ever takes place or can even happen*, essentially, whether or not it is *possible*. Questions about the end of philosophy, and thus of the end of the historicity of history, still abound. Some pose more productive challenges to the thinking of “what, if anything, comes next?” than others do. Nevertheless, a sense of community is (oddly enough, some may say) formed around the asking of the question of the end or the death of philosophy. And this is to be expected, when the point is just to a Heideggerian *overcoming* (*Überwindung*) of metaphysics. It is the responsibility of each individual to interrogate the limits of “a sort of axiomatic, a system of values, norms and regulating principles” (Derrida, 1994, p. 2.) that justify “the existence then of a properly philosophical space like UNESCO.” (Derrida, 1994, p. 2.) “For,” Jacques Derrida warns, “such a situation and such a duty are more particular than it seems. And this can lead to fearsome practical consequences.” (Derrida, 1994, p. 3.) Such as the temptation to take a stance on one side or the other of philosophy, *with or against* those who desire to remember and keep alive its memory or those who choose to forget the historicity of metaphysics and forswear the finality of its death. “A community of the question about the possibility of the question” is what Derrida calls the publicly academic space of a more productive ground of inquiry into the right to

philosophy than one of either support or diffidence. (Derrida, "Violence and Metaphysics," p. 80.) It would neither reject nor embrace the Eurocentric historicity of the Western thinking and its epistemic-cultural specificity that is articulated via humanism as the infinite perfectability of subjective being: the finding of the *nature of the self* and its center at the cost of losing affinity with the other. It could not, because it is a "community of the question" – a community wrought of dissensus and not of consensus. Its potential lies in the openness of its capacity to honor and respect the value of difference, to welcome the impossibility of alterity, but not to dismiss or celebrate the ground of *au courant* memory for its own sake, over the unfamiliar archive of another. So, rather than dismantling the arguments of those who would like to see the demise of the right to philosophy and its Eurocentric historicity, Derrida has attempted to answer and is continuing to address the larger question of the death of metaphysics, its future, both directly and obliquely, because none of the answers posited are as yet satisfying enough to do justice to the persistent problem of *finding a way out of philosophy*. Certainly, there is an *aporia* at work here that seeks refuge in its displacement. And Derrida construes its difficulty in the following way:

This Eurocentric discourse forces us to ask ourselves . . . whether today [referring both to the context of the lecture and to the epochal dimension of empirical time] our reflection concerning the unlimited extension and the reaffirmation of a right to philosophy should not both *take into account and de-limit* the assignation of philosophy to its Greco-European origin or memory. At stake is neither contenting oneself with reaffirming a certain history, a certain memory of origins or of the Western history (Mediterranean or Central European, Greco-Roman-Arab or Germanic) of philosophy, nor contenting oneself with being opposed to, or opposing denial to, this memory and to these languages, but rather trying to displace the fundamental schema of this problematic by going beyond the old, tiresome, worn-out and wearisome opposition between Eurocentrism and anti-Eurocentrism. One of the conditions for getting there – and one won't get there all of a sudden in one try, it will be the effect of a long and slow historical labor that is under way – is the active becoming-aware that

philosophy is no longer determined by a program, an originary language or tongue whose memory it would suffice to recover so as to discover its destination, that philosophy is no more assigned to its origin or by its origin, than it is simply, spontaneously or abstractly cosmopolitical or universal. What we have lived and what we are more and more aiming for are modes of appropriation and transformation of the philosophical in non-European languages and cultures. Such modes of appropriation and transformation amount neither to the classical mode of appropriation that consists in making one's own what belongs to the other (here, in interiorizing the Western memory of philosophy and assimilating it in one's own language) nor to the invention of new modes of thought which, as alien to all appropriation, would no longer have any relation to what one believes one recognizes under the name of philosophy. Derrida, 1994, p. 3

No discourse "disciplined" body of knowledge claiming epistemic status, such as philosophy is and does, *self-consciously* undermines its grounding conceits in both methodology and content. The principle of noncontradiction forbids it. What governs the institutional legitimacy of philosophy as a *scientific endeavor* is its ability to render the logic of its conclusions accountable *to* and *for* the provisions of episteme laid out by the historicity of its own doctrines of self-evident truth and the generalizability of conclusions regarding the study of empirical phenomena: what its discourse says and reveals, confirms and proves by way of an experiential facticity, about *being-in-the-world*. In this respect, an ethical moment attends the academic pursuit of knowledge. It occurs when thinking becomes *like a science*, becomes "philosophy," is conceived as a universal project, inaugurates a discipline replete with models of practice to be guarded, and is not defined idiosyncratically as the general process of thought. This distinction, besides giving credence to the institutional and pedagogical formalization and formulizability of the human intellect for and within the structures of the modern university, remains highly problematic. The division between "philosophy and *Denken*, thinking," reenforces the ethico-epistemic specificity of academic responsibility in this manner by setting down

the template for marking out the limits of the paragon of a community (to be) instituted, whereby the laws it creates ultimately support and mobilize a divining line that distinguishes those “who belong” to it from those “who do not” and, in all probability, never will. (The “Roundtable Discussion” on Jacques Derrida’s “Des humanités et de la discipline philosophiques”/“Of the Humanities and Philosophical Disciplines” in *Surfaces* Vol. VI.108 (v.1.0A-16/08/1996), p. 2.) The partisanship of discipline and disciplinarity plays upon the need for philosophy to be affiliated with the historicity of a “culture.” Here we must give way to caution, though, not to presume to know too much. “There are cultural aspects of philosophy,” Derrida maintains, “but philosophy is not a cultural phenomenon.” What does this mean, exactly, in both the narrow and broader sense of a community of shared and differing interests?

2. This brings us to the second point. To say that philosophy is a cultural phenomenon would be to universalize it and to deny “the relationship between philosophy and natural languages, European languages,” (Derrida, 1994, p. 2.) living and breathing languages, that are proper to and establish the propriety of philosophy as a Western invention of the consciousness of the West and the articulation of its archive. And Derrida is sufficiently clear about this undeniable linguistic historicity, while attempting “to avoid the opposition between two symmetrical temptations, one being to say that philosophy is universal”: (Derrida, 1994, p. 2.)

Today it’s a well-known phenomenon – there is a Chinese philosophy, a Japanese philosophy, and so on and so forth. That’s a contention I would resist. I think there is something specifically European, specifically Greek in philosophy to say that philosophy is something universal. . . . Philosophy is a way of thinking. It’s not science. It’s not thinking in general. So when I say, well, philosophy has some privileged relationship with Europe, I don’t say this European-centrally but to take seriously history. That’s one temptation, to say philosophy is universal. (Derrida, 1994, p. 2)

The closure of philosophy does not mean a gathering together of the Greco-European

reality of its roots and forcefully bringing them to an end that would, for all intents and purposes, lack any semblance of historicity and is then without a future. The breakthrough of *what-is-to-come* must always arise out of the resources of a past thinking that cannot be effectively renounced. The trace of Greco-European cultural memory in philosophy will neither allow itself to be eradicated nor to be abandoned at the limit of the archive of knowledge it *is* and *represents* in method, form, and content. The first “temptation” leads to the second, both contrary and complementary, one Derrida warns us about – the desire to say:

well philosophy has only one origin, a single pure origin that is its foundation, its institution, through a number of grounding concepts which are linked to Greek language, and we have to keep this in memory and constantly go back to Greece and back to this Greek origin, European, through anamnesis, through memory, to what philosophy is. This is a symmetrical temptation which I would like to avoid. Derrida, “Des humanités,” p. 2.

The Eurocentric myopia of this monocultural view of the archive of the Western episteme is another peril of taking sides without actualizing sufficient precautions against the irresponsibility of academic solipsism. Magnifying the question of the historicity of philosophy and of the purity of its Greek origins, the example foreshadows the necessity of moving beyond the concept of a universal thought and recognizing the rise of the cosmopolitical condition that Kant predicted as a moment in the infinite process of eternal becoming, or the point in history where a giant step in the progress of humanity can be seen resulting from an outgrowth of the global self-awareness and situatedness of human being. Derrida stresses the virtues of “another model” (Derrida, 1994, p. 2.) whose approach to truth cannot be distilled quite so easily into a program of “Eurocentrism and a simple-minded anti-Eurocentrism.”: (Derrida, 1994, p. 2.)

that is, while keeping in memory this European, Greek origin of philosophy, and the European history of philosophy, take into account that there are

events, philosophical events, which cannot be reduced to this single origin, and which meant that the origin itself was not simple, that the phenomena of hybridization, of graft, or translation, was there from the beginning, so we have to analyze the different philosophical events today, in Europe and outside of Europe. (Derrida, 1994, p. 2.)

In essence, the attempt to make philosophy live out its future after the historicity of its Greco-European past requires the space of an *aporia* “that cannot be locked into this fundamentally cultural, colonial, or neo-colonial dialect of appropriation and alienation.” (Derrida, 1994, p. 4.) There must be more. “There are other ways for philosophy than those of appropriation as expropriation (to lose one’s memory by assimilating the memory of the other, the one being opposed to the other, as if an *ex-appropriation* was not possible, indeed the only possible chance).”³ Derrida is right. The testimony of memory and its reaffirming of an ethical response and responsibility to the historicity of the past are important for inscribing and building the “horizon of a new community.” (Derrida, 1994, p. 3.) It is not a matter of reasonable speculation: as the “speculative moment within the academy”⁸ will not do justice to rethinking the new situation of nations and States, of peoples, that must “transform their assumptions” (Derrida, 1994, p. 3.) (discussion 3) in relation to what we now know is the urgent necessity of “displacing some concepts which are absolutely essential to th[e] constitutions” (Derrida, 1994, p. 3.) of international institutions like the United Nations and UNESCO. The cosmopolitical hybridization of empirical and epistemic identity Derrida speaks of does not involve trying to erase the history of one’s own memory by working (in vain) to appropriate the effects and affectivity of another archive – the archive of the “other” – whose expropriation would be causally determined via the need for a political maneuvering or strategically motivated as the willful adoption of its tenets would just happen to jibe with the dominant ideology of the day. Nor does it imply making an attempt to start over without history by pursuing misguided

efforts to efface the contextual and institutional specificity of subjectivity through a haphazard rejection of the philosophical grounding of one’s sense of *being-in-the-world*. On the one hand, a rethinking of “Eurocentrism and anti-colonialism” (Derrida, 1994, p. 4.) as “symptoms of a colonial and missionary culture” (Derrida, 1994, p. 4.) would facilitate other beginnings and other directions for the infinite progress of human being. On the other hand, “a concept of the cosmopolitical that would still be determined by such opposition would not only still concretely limit the development of the right to philosophy but also would not even account for what happens in philosophy.” (Derrida, 1994, p. 4.) Do we have any chance of surpassing the hindrances and obstacles of respecting a desire to promote and protect the call for either the appropriation (expropriation) or ex-appropriation of Western metaphysics on a global and international scale?

If philosophy could ever hope to overcome the impossible dream of achieving its own end, it would be precisely from a curious rupturing of the idea of its historicity, the memory of its *being-past*, which, of course, could and would never happen. And we should not want an expunging of the history of philosophy to occur, if it were even possible. Metaphysics does not have to be forcefully sedated, sanitized, and subdued. Also, we do not have to issue a proclamation that would render it alive or sentence it to death. Derrida explains, “Not only are there other ways for philosophy, but philosophy, if there is any such thing, is the *other way*. And it has always been the *other way* (Derrida, 1994, p. 4.) To be unequivocal, philosophy “has always been bastard, hybrid, grafted, multilinear, and polyglot.” (Derrida, 1994, p. 4.) The teaching body of the discipline has always known this fact to be true. Pedagogical systems highlighting methods of recitation and repetition in the delivery of its curriculum were designed as a defense against a mnemonic underdetermination of the totality and authenticity of philosophical archive. By this I mean the competing models and systems

of the reason of Western episteme that explicate the ontico-ontological sources of human consciousness and being. What signals the “crisis of philosophy” and leads to a questioning of the value of its teaching and learning – thereby feeding the naive illusion of its untimely demise – are the meta-conditional links of possibility, to be more specific, the *conditions of impossibility* within its complex lineage that work to destabilize the history of philosophy and, consequently, open up the concept of philosophy to what is not “philosophy proper” or “proper to philosophy.” It is this realization of an originary difference always already present within the writing of its archive that displaces and dislocates the authority of its power to signify and *speak for* the truth of itself. The violence of alterity as the immutable trace of the difference of another thoroughly permeates the historicity of Western knowledge. For “philosophy has never been the unfolding responsible for a unique, originary assignation linked to a unique language or to the place of a sole people. *Philosophy does not have a sole memory.*”

3. We will now consider the third point. The working within and against a tradition of canonical associations wrought by the instauration of memory and the limitations of its capacity exemplified in the act of forgetting (*lethe*) brings out the tensions of disassociation and dissonance that redefine the path of metaphysics. To achieve a spatial and temporal closure of “first philosophy” involves a segue to something *other than philosophy, a thinking of philosophy lacking philosophy*, where “we must adjust our practice of the history of philosophy, our practice of history and of philosophy, to this reality which was also a chance and which more than ever remains a chance” (Derrida, 1994, p. 4.) for the impossibility of realizing the headings of a philosophy is yet to come. Derrida anticipates the future after metaphysics taking place along these lines of a debt and duty to the tradition of the past traced out by the limitations of memory and its openness

to an expansion of the difference of itself as the *khora* of the other. It is not only a matter of affirming the existence of philosophy, but of recognizing and acknowledging its natural right to determine the grounds for asking the questions about its sources, its limits (*peras, linea*), and its future, if only to establish the boundaries of debt and duty that would serve to prepare us for a thinking of what comes next from what came before. Derrida is quite clear on this: “Philosophy has always insisted upon this: thinking its other. Its other: that which limits it, and from which it derives its essence, its definition, its production.” (Derrida, 1982) One cannot beat the anti-metaphysical drum (*tympan*) too loudly and still expect to hear the echoes of a timelessness that reserved the task of thinking. Indeed, it would be unwise to “philosophize with a hammer”, (Derrida, 1982, p. xiii.) like Friedrich Nietzsche’s Zarathustra, and ponder on how best to go about the mobilization of a “noisy pedagogy” that would displace the internal sound of seeming truth in the ears of those who enjoin a claim to knowledge with the light of a sagacity drawn from the premises of what is a risky (re)visioning of epistemology poised “to transform what one decries” (Derrida, 1982, p. xiii.) in metaphysics. The danger is that, as Derrida has warned, “in taking this risk, one risks nothing at all,” for what is *unthought* and therefore *untaught* always already opens the future of a history of thinking and directions of teaching that are “yet to come” (*à-venir, Zu-kunft*).

Defining Openness in Education

Theo Hug

Department of Psychosocial and Communication Research, Institut für Psychosoziale Intervention und Kommunikationsforschung, University of Innsbruck, Innsbruck, Austria

Synonyms

Anarchic education; Education for all; Educational commons; Edupunk; Humanistic education; Massive open online courses (MOOCs); Open education (OE); Open educational resources (OER); Open learning; Transformative learning

Introduction

Characteristics of openness can be found in many respects throughout the history of education. For thousands of years, children educated themselves for a large part through more or less free play, exploration, sharing, and exchange. Although children's play for its own sake might seem a prototypical example for openness in education at first sight, dynamic interrelationships of dimensions of opening and closure are essential for a differentiated understanding of the various aspects of free play, open education, and its conditions and constraints.

This argument can be further illustrated by contrasting educational ideals in transition from closed to more open societies. On the one hand, philosophers like Protagoras, Democritus, or Socrates who called for comprehensive education for "free citizens" in ancient Greece set a basis for public education and contributed to transitional processes from tribalism to humanitarianism or, in other words, from closed to open forms of society where, at least ideally, rules, values, customs, and also taboos could be questioned and criticized. On the other hand, opening up education was meant

for some and not for all. In Plato's model of an educational State, for example, it is only male adult philosophers who can obtain the highest level of education by way of stepping out of the cave with its shadows and false images.

Ambivalences, polarities, and contradictions between freedom and open space for development, on the one hand, and constraints and enforcement on the other, have been discussed in various educational contexts. The spectrum extends from calls for openness to fulfilling one's moral obligations as an element of Confucian ethics in order to foster a harmonious authoritarian society and Kant's view of humans who in contrast to animals need education in terms of nurturing, disciplining, instruction, and moral training, to calls for reform pedagogies – aimed at opening up rigid educational systems, at the same time privileging bourgeoisie – as well as to subsequent calls for open learning and a pedagogy of liberation or freedom (P. Freire) and related praxis oriented and activist movements.

Today, we find a variety of initiatives aimed at opening up education by the use of digital media technologies, open educational resources (OER), and creative commons (CC) licenses. Notions of open education are often linked to notions of open source and free/libre open source software (F/LOSS), open access, open society and free culture, open science and knowledge commons, open government and open innovation as well as further related notions. For the most part, recent debates about education for all, enabling universal education, or free educational infrastructures can be characterized by a kind of historical amnesia – calls for education for all are anything but new, they can be traced back at least to the work of Johann Amos Comenius (1592–1670).

Different Approaches to "Openness" and "Education"

Although terms like "open education" (OE) have become increasingly a matter of course – especially in the context of educational

policies – many different meanings of “openness” and “education” are being used in everyday life as well as in pedagogical, political, economic, aesthetic, and scientific discourses. Depending on linguistic and performative aspects and personal and discursive contexts, we find a manifold of partly interchangeable, complementary or conflicting conceptions. The terms “openness” and “education” are often used metaphorically or by means of implicit or applicative definitions and less frequently on the basis of explicit and clear definitions.

To give a few examples, openness in education can refer to pedagogical attitudes towards fostering and maintaining processes of dialogue, reflection, and a climate of mutual learning, listening, and recognition; openness in the process of self-formation (*Selbstbildung*) may refer to approaches for enabling personal growth, for successfully dealing with shifting societal challenges, or to a more relaxed relation to oneself; crossing borders in terms of cognitive, affective or physical mobility in the context of debates, (in-)human encounters, traveling, or migration can be called educational whereby openness may refer to enhanced cognitive skills, emotional or communicative competencies, or to a more skillful performance through embodiment; opening up education can be defined as an indispensable condition for the development of democratic orientations, as an initiative to establish open plan classrooms, as a measure to increase learners’ choices and options for access to education, as a transnational educational policy aimed at innovative teaching and learning, as a new edition in the history of promises of education for all, as an imperialistic or neocolonialist endeavor, etc.

Different understandings refer to different kinds of things, subject areas or phenomenal domains, such as aims, attitudes, intentions, endeavors, group processes, methods, measures, self-perceptions, conditions, relations, policies, initiatives, institutions, and personality characteristics. Furthermore, it is obvious that different approaches correspond with different goals and purposes including notions of education for its own ends.

Pedagogical Approaches

In a pedagogical context, an open approach to openness in education might start by asking for synonyms of “open” and “education” or closely related terms. Spontaneous associations and individual interpretations can be depicted, for example, in the form of a matrix by listing basic meanings and synonyms in the first line or column. Of course, other terms than those mentioned in Table 1 may arise, such as “uncovered,” “unprotected,” “free from concealment,” or “not restricted to members of a particular group” for “open” and “schooling,” “instructional principles,” “learning to learn,” “distribution of content,” “transmission of knowledge,” “pedagogical interaction,” “touching events,” or “biographical upheavals” for “education.” For one thing, understandings and conceptions of “open education” can be considered in the fields of an emerging matrix as shown by way of example in Table 1; for another thing, existing notions of “open education” or “openness in education” can be positioned tentatively in one or more of the fields. By means of such an iterative process and with preliminary results multiple kinds of definitions and metaphorical uses of key concepts as well as possible related goals can be discussed. In a further step, contexts of use, language games, and discursive relationships can be opened to debate with reference to both the ideas of learners and educators involved and the relevant literature available (cf. for example, Nyquist and Hawes 1972; Nyberg 2010 [1975]; Peters 2010; Deimann and Peters 2015). Moreover, alternative approaches, procedural steps, and modes of visualization as well as meta-reflexive and evaluative methods can be considered.

Modes of meta-reflexive considerations including self-reflection on the level of individuals, groups, institutions, and organizations can act as an important indicator for the analysis of different forms and limitations of openness in education. This counts for earlier forms of open learning, self-organized study-groups, open plan classrooms, or open schooling, just like for more recent developments associated with open universities, open courseware, and open education. In a

Defining Openness in Education, Table 1 Example for an OE-matrix – at the crossroads of interpretations of . . .

Education	Open				
	Without barriers	Allowing for passage	Broad minded	Free	Permeable
Training	Easy to access	Eligibility certificates	Free choice of material	No or low monetary costs	Coming and going
Learning in formal contexts	No eligibility assessments	Authorization	Transformative learning	Self-organized learning	Revising and reusing OER
Self-learning	Self-empowerment	Crediting open learning, self-improvement	Critical literacy	Educational commons, edupunk	Sharing, redistributing content
Teaching	Teaching as learning	Professional growth	Democratic orientation	(Re-)use of OER	Team-teaching
Lesson, class	Low-threshold access	Skippping classes	Global education	Lessons at no (obvious) charge	Flipped classroom
Formation (<i>Bildung, dannelse</i>)	Free choice of educational material, rhizomatic education	Social mobility	Enabling self-determined processes	Personal enrichment, education for its own sake	Choices for individuals in the course of education
Upbringing (<i>Erziehung</i>)	Anarchic education	Adequate bonding	Personal maturation	Liberal education	Intercultural education

D

broad sense, claims for open education are always dealing with tensions between conceptual and performative dimensions as well as with differences between self-determined and self-directed learning. In that sense, open education should be considered as a never-ending process dealing with limitations and limited resources so far, opening up new horizons, and encountering new limitations from now on. Further, educators are well advised to take into account that life itself is educating, too. It is not only intentional forms of initiating and guiding or accompanying educational processes that are relevant here – it is also ongoing implicit education in everyday life and mediated life-worlds.

Educational Policies

Open education is widely perceived as a political or social project, sometimes as a grassroots movement or as an economic and technological opportunity to make money. In the twentieth century there were various initiatives aimed at opening up education. In Europe and the USA, open plan classrooms became popular from the late 1950s to the 1970s. In Austria, for example, free school books, free use of public transport for students,

and democratic structures in university legislation were introduced in the early 1970s, while at the same time tuition fees were abandoned. In the postcolonial area also in many African countries, free access, free textbooks, and free feeding were strengthened.

An international effort for education for all (EFA) bringing together governments, multilateral agencies, and non-governmental organizations was launched in Thailand in 1990. Respective goals have been taken up by the United Nations in its Millennium Development Goals in 2000, followed up by a fast track initiative by development banks and government funders in 2002. In the same year, the first public mention of the term “open educational resources” (OER) occurred at the UNESCO forum on the Impact of Open Courseware for Higher Education in Developing Countries (UNESCO 2002). The discussions focused on open courseware and possibilities of improving access to open teaching and learning resources mostly in what the United Nations regarded as developing countries.

At the same time, the first 50 courses in the opencourseware (OCW) project at Massachusetts Institute of Technology (Cambridge/MA, USA)

have been published online (Iiyoshi and Kumar 2010). This project and its institutional commitment to openly share educational resources have been further developed up to the present day.

Among the most recent prominent initiatives are UNESCO's "Paris OER Declaration" from the year 2012 aimed at the promotion and use of OER to expand access to education at all levels, the Nordic Open Education Alliance founded in 2013, and the initiative of the European Commission dedicated to opening up education from 2013.

Theoretical Considerations

So far, a comprehensive and widely recognized theory of openness in education has not been presented. However, conceptual details are being discussed in blog posts and essays as well as in academic research papers. Accordingly, various forms of discourse, degrees of differentiation, and scopes of claims are being considered. In addition, there are translation problems with key terms in education, and territories and responsibilities for educational issues are not as clear-cut as, for example, in sociology or mathematics.

Definitions of conceptual key issues regarding openness in education depend upon the perspective of the definer and his or her basic assumptions concerning the question of what exactly educational studies and research are. Those who represent educational studies as a distinct discipline in the tradition of humanist philosophy and the enlightenment might refer to the development of open-minded reasoning, to enhanced ways of thinking (H. Arendt), or to flexible and thoughtful building on educationability (*Bildsamkeit*) – a term originally coined by Johann Friedrich Herbart (1776–1841) as an endemic key term in pedagogy. Whereas those who conceptualize educational systems as operating mainly as agencies of the State might aim at "opening up" those systems in terms of reforms or revolution. Moreover, those who are questioning schooling as to indoctrination might follow ideas of deschooling (I. Illich). Others, who prefer an interdisciplinary approach as regards educational economics, for example, might focus on free access to massive open online courses (MOOCs) and largely

scalable "useful" educational content in order to optimize employability. Those who associate education in the first place with "biopolitical control" of populations and especially legitimized, organized practices, in a Foucauldian sense, might call for opening up education in relation to degovernmentalization and the search for alternative subjectivities. Meanwhile, those who conceptualize education in the context of post-, trans-, or para-humanist discourses might vote for the development and intense use of educational applications based on the most recent achievements in biotechnology and artificial intelligence.

The list could be continued easily by reference to all kinds of (inter-)disciplinary approaches and -isms in educational research. There are many definitions of openness in education if any. In view of the paradigmatic relevance of basic assumptions for the conceptualization of openness in education and in order to avoid the unintended promotion of paradigmatic perspectives, it seems crucial to foster meta-critical perspectives at least in the following respects:

- Open, opening up, and openness as relevant to education tend to have positive connotations. However, this should not keep us from remembering that these terms do not *per se* represent values. Whether we can appropriately speak of positive or problematic values will depend on contextual and situational conditions, on the constellation of actors, on study requirements and educational objectives as well as on desired or undesired outcomes and secondary effects. Just as in some group processes, trust can only emerge when the group members are able, at least temporarily, to rely on a closed structure, advocating unlimited openness may be counterproductive. Or the other way round: opening up education as a means of rejection and criticism of institutional structures may go hand in hand with the incorporation of favored tools and structures into the educational system which only serve certain interests. Thus, it is important to consider limitations as well as paradoxes and ambivalences that correspond with particular forms of openness. This especially applies to debates about options for the

monetization of educational mass events and business models in keeping with the motto “for-profit education for all” providing access and calling for openness and sharing and at the same time using proprietary software and “all rights reserved” approaches.

- Sharing is a concept that has come to characterize digital media cultures. It emerged as significant theme in media studies, educational research, political theory, and economics, in general, and, in particular, in open education and open content strategies. However, notions of sharing often remain undertheorized in the open educational resources movement if they are not mixed up with notions of exchange and/or gift. There are weak and strong forms of sharing to be distinguished (cf. Hug 2014), and there is a need for a deeper understanding of expanding structures as well as subjectivities and (im-)materialities of sharing, if we want to meet the requirements of the development of knowledge commons, educational commons, and open archives in networked media cultures (cf. Missomelius et al. 2014). Understanding grammars of sharing and cultural-economic alternatives requires rethinking the public-private nexus beyond the dichotomy of capitalist markets and public economies.
- As for open standards, quality criteria, and didactical aspects, the question remains whether “open educational resources will in future define a *sui generis* (media) pedagogical standard of education” (Bergamin and Filk 2009, p. 11; bold in orig.). On the one hand, issues of consumer cultures “in which everything may be consumed for free” (Bergamin and Filk 2009, p. 26) should be taken seriously if open education aims at formation (*Bildung, dannelse*). On the other hand, educationalists often underestimate the educational potentials of popular media cultures and the creative power of design theory or the theory of medial forms (R. Leschke).
- Regarding the anthropological and normative aspects of openness in education, there is a demand for conceptual clarifications between Scylla of media-phobic tendencies in

education or radical normativity towards a specific conception of human beings and Charybdis of media-philic claims for radical openness which hardly allow for critical perspectives. Among the multiple uncertainties we are facing in education, there are manifold socio-technical connections between machines, algorithms, and human actors; demands for action in view of unknowing and little knowledge; multiplex entanglements of cultural, social, biological, and technical dimensions of information processing; multiple identities of individuals enabling openness towards others; and polymorphous medial selves (M. Faßler) dealing with the sensory enormousness of the world. Addressing these complexities and post- or trans-humanist challenges require thoughtful consideration rather than undercomplex statements prevailing in the OER movement.

- Researching openness in education should involve a commitment to opening up meta-critical perspectives for more general reasons too. Critical reflections on problematic forms of monopolization of critical positions or the usurpation of the power of critique are rejected rather than welcomed in academia. Then again, we find problematic turning-points such as criticism of ideology turning into an ideological endeavor, critique of the culture industry as part of the arts and entertainment industry, regovernmentalization in the name of degovernmentalization, or involution of democratic achievements in the name of democracy. Without meta-critical thinking and self-application of critique, notions and practices of openness in education might manifest as (self-) delusion or collective strategy primarily sustaining today’s work and world orders rather than as future-oriented forms of education and knowledge for all.

Conclusion

Openness in education can be regarded as an operative fiction and as an educationalization formula (sensu H. Veith) that has been interpreted in

many ways throughout the history of education. As far as interpretations are related to the achievements of the enlightenment, education for openness remains an ambiguous endeavor including openness to criticism, intellectuality, freedom of expression, reasonable and sober-minded acting, bureaucratization of society as well as Eurocentric thinking and European colonialism. Today, openness is “at a crucial stage regarding its future direction” (Weller 2014, p. 202). If we consider education as both a public and a private good and if we take it seriously that all knowledge is contextually bound, context-sensitive concepts and practices open to the future, as well as polylogical approaches, are needed in order to enable critical mediation between individual and cultural memories and between human agency and the ongoing work of algorithms. Closely examined, it can be said that education remains open in two respects: within a limited lifetime and from phylogenetic perspectives of human development.

Introduction

During the nineteenth century, cultural historian Jacob Burckhardt presciently asserted that “the essence of tyranny is the denial of complexity,” a denial manifested in much contemporary curriculum theory, policy, and practice. Teaching, learning, and curriculum making have been redefined by reference to a culture of accountability,

performance, and measurability that ignores complex processes and outcomes, which are not readily apprehended or comprehended by conventional measurement technologies.

In the late 1960s, Gilles Deleuze began to formulate some of the philosophical significances of what is now known as “complexity” (and/or “complexity theory”) and many of the concepts he created (often in collaboration with Félix Guattari) have assisted curriculum scholars in acknowledging complexity and resisting the toxic politics of complexity reduction. This entry draws on selected examples of curriculum scholarship that play productively with Deleuze and Guattari’s (henceforth Deleuzoguattarian) concepts such as assemblage, becoming, intensities, line of flight, machinic, nomad, order-words, rhizome, and multiplicity.

Early Sightings of Deleuze and Guattari in Curriculum Literature

William Pinar and his coauthors provide a comprehensive overview of the earliest appearances of Deleuzoguattarian concepts in Anglophone curriculum theorizing in a chapter titled “Understanding curriculum as poststructuralist, deconstructed, postmodern text” (Pinar et al. 1995). They identify Peter Taubman as the “first curriculum theorist in North America to introduce poststructuralism to the curriculum field” (p. 476) via his 1979 doctoral dissertation, *Gender and Curriculum: Discourse and the Politics Of Sexuality*. Pinar et al. (1995) note that one of the strategies Taubman offers for resolving what would be “rephrased in later debates conducted by feminist theorists over essentialism versus constructionism” deploys a “Derridean-Deleuzian deconstruction of totalities” in which “sexuality emerges as ‘intensities, dispersed whisperings, connections, cominglings, communions and juxtapositions of de-gendered bodies and pleasures’” (pp. 477–478). The significance of *intensities* as a generative concept for curriculum work is portrayed in Marg Sellers’ (2013) reconceptualization of young children’s play as “intensities of becoming”:

play is not so much thing or event but movement, with/in/through which change occurs continually... This sense of play... generates an openness as the movement of the play becomes somewhat indescribable, indefinable – an elusive mo(ve)ment [which] may go some way towards explaining difficulties in defining the play that children do... In Deleuzo-Guattarian understandings, children’s play(ing) happens in [a] kind of potential space as a machinic assemblage. In such potential, liminal spaces an intensity of forces operates... it is the play in-between that generates movement – if there is insufficient play, things seize, nothing happens (p. 116).

Pinar et al. (1995) summarize the contributions of four other North American curriculum theorists who foreground Deleuzoguattarian concepts, namely, Jacques Daignault, Clermont Gauthier, Jan Jagodzinski, and Wen-Song Hwu (note that Daignault and Gauthier are Francophone Canadians and few of their publications are readily available in English). Pinar et al. (1995) point out that Daignault’s writing, “relying as it does on allusions to the work of other poststructuralist theorists, on references to musical theory, on anagrams, puns, linguistic arabesques, and neologisms, can prove difficult for the beginning student” (p. 480), but that it is worth persevering because “Daignault brilliantly explores the spaces, the gaps, the ‘in-betweens’ and the differences within language, thought, the subject, and our ways and modes of conceiving ourselves and curriculum” (p. 480).

[Daignault] follows Deleuze’s move to liberate difference and to combat totalizing modes of thought... Thinking is not representational, Daignault insists... Rather, he wishes to articulate the space between words and concepts... He wishes to think the middle... By phrasing curriculum as thinking Daignault implies his opposition to any reification or belief in representational thought, for curriculum as thinking is always moving, diversifying, or to use Deleuzian terms, is ‘nomadic’ (Pinar et al. 1995, pp. 482–483).

To “think the middle” gestures toward another Deleuzoguattarian concept, *rhizome*. Rhizomes have no beginnings or ends but are always in the middle: beginnings and ends imply a linear movement, whereas working in the middle is about coming and going rather than starting and finishing. Sellers and Gough (2010) quote

semiotician Umberto Eco's assertion that "the space of conjecture is a rhizome space" (p. 594) and posit rhizome as a tool for "thinking differently" in curriculum inquiry:

Deleuze and Guattari's rhizome. . . is presented as a way to disrupt the hegemony of the popular arboreal metaphor for knowledge organization. In one swift move, from the singularity of the tree of knowledge to multiplicities of rhizomes for knowing, it is possible to imagine other organizing ways that perturb a predominant worldview – ways that are not unlike those involved in decentering the Earth within the then known universe. It is worth remembering how difficult this was. . . (p. 606).

A rhizome space is also more hospitable to nomadic than to sedentary thought. Whereas much Western philosophy, history, and science adopts a sedentary standpoint, nomadic subjectivity allows thought to move across conventional categories and disturb "settled" concepts, signs, and theories.

Pinar et al. (1995) note that Jan Jagodzinski's work "exemplifies several poststructuralist characteristics, including imagistic reorderings of words intended to challenge taken-for-granted decodings" (p. 490). They do not refer directly to Jan Jagodzinski's deployment of Deleuzoguattarian concepts, but this can be inferred from their discussion of the six "aesthetic layers" (line, color, texture, size, mass, and space) "through which the curriculum is felt" (p. 490). This is evident in Jan Jagodzinski's discussion of line, in which he asserts: "Educationally, we must recognize that all lines are bridges to new directions" (quoted in Pinar et al. 1995, p. 490). This echoes the Deleuzoguattarian concept of *line of flight* or *detrterritorialisation*, which Kaustuv Roy (2003) explains as "a movement by which we leave the territory, or move away from spaces regulated by dominant systems of signification that keep us confined to old patterns, in order to make new connections" (p. 21; italics in original). Roy (2003) continues:

To proceed in this manner of detrterritorializing, we make small ruptures in our everyday habits of thought and start minor dissident flows and not grand 'signifying breaks,' for grand gestures start their own totalizing movement, and are easily captured. Instead, small ruptures are often imperceptible, and allow

flows that are not easily detected or captured by majoritarian discourses (p. 31).

Ruptures and flows are also invoked in Pinar et al.'s (1995) quotation from Gauthier who conceives education "as a *machinic* production formed of meetings and breaks and of flow" (p. 491, emphasis in original; cf. Marg Sellers' interpretation, quoted above, of children's play as a "machinic assemblage"). They also note Gauthier's "explosion" of taken-for-granted conceptions of action research, which includes "the quintessential poststructuralist assertion: 'action research is above all a matter of language'" (p. 49) and conclude that Daignault's, Jan Jagodzinski's, and Gauthier's curriculum theorizing "disturbs the usual linear logic we have come to accept as being synonymous with rationalistic curriculum theory" (p. 491).

Pinar et al. (1995) describe Hwu's curriculum theorizing as drawing on Daignault's work to sketch "possible links among poststructuralism, Chinese Taoism and Zen," noting that, like poststructuralism, Taoism and Zen are "paradoxical" and "employ language in ways that are not dependent upon extra-linguistic referents" (p. 492).

Hwu notes that in poststructuralism the notion of identity is displaced by that of difference, undermining that autobiographical scholarship which rests on a foundation of an authentic self. Such an idea is simply a story one tells oneself. . . Hwu argues that while psychoanalysis is false and narratives about the self are illusory, still we live as if our experience were true. The point is. . . to be playful about the stories we tell, recalling their illusory character and mystifying functions. He quotes Deleuze: "No longer are there acts to explain, dreams or fantasies to interpret, childhood memories to recall, words to signify; instead there are colors and sounds, becoming and intensities" (pp. 492–493)

Hwu concludes that "the role of curriculum theorizing [after poststructuralism] is not to formulate a global analysis of the ideologically coded. . . Curriculum functions to displace discursive practices, such as self-formation, sense-making, historical awareness. . . [and explore] the possible connections among those fragmentations and differences" (quoted in Pinar et al. 1995, p. 493).

Growing Deleuzoguattarian Curriculum Scholarship

Although Pinar et al., writing in the mid-1990s, could identify only a handful of curriculum scholars informed by Deleuze (or Deleuze and Guattari), during the mid- to late 2000s more than a dozen came to light. These (and the curriculum aspects they explore) include Ronald Bogue (literature, cinema, and other arts), David R. Cole (English and pedagogy), Claire Colebrook (gender, literary theory), Gary Genosko (technoculture, popular pedagogy), Noel Gough (environmental and science education, internationalization, globalization), Zelia Gregoriou (ethics, multiculturalism, identity), Eileen Honan (English and literacy), David Lines (music and other performing arts), Inna Semetsky (philosophy, semiotics), Kaustuv Roy (political and social theory), Marg Sellers (early childhood education), and Elizabeth St. Pierre (language and literacy education). All the aforementioned contribute to Semetsky's (2008) *Nomadic Education: Variations on a Theme by Deleuze and Guattari* (some of them, like Bogue and Colebrook, were already established Deleuzeans in fields other than education, and others, like St. Pierre and Semetsky, were working with Deleuzean concepts in education during the preceding decade; more than half of these scholars had previously published on Deleuze and education in a special issue of *Educational Philosophy and Theory* [vol. 36, no. 3, 2004]). Other curriculum scholars who actively pursued Deleuzoguattarian themes during this decade include Diana Masny (multiple literacies; see Masny and Cole 2009) and Warren Sellers (e-Learning, higher education learning environments; see Sellers and Gough 2010).

In *Teachers in Nomadic Spaces: Deleuze and Curriculum*, Roy's (2003) purpose is "to demonstrate that Deleuzian pragmatism can be appropriated and then reconstituted through educational experience to form an important conceptual matrix for advancing thinking in curriculum" (p. 16). Roy's study addresses perennial practical problems in the stressful lives of newly inducted and in-service teachers in urban schools, while at the same time affirming the "generative

possibilities of the situation" (p. 2). He seeks "to introduce a 'swerve' or a deviation in the plane of taken-for-granted assumptions by means of which a new experiment in thought could be inserted in the interstices" (p. 2). Roy does not offer any recipes for curriculum practice, but as a quotation from Deleuze at the end of his book suggests, his "fieldwork in theory" (p. 1) can be understood as an electric circuit:

There are . . . two ways of reading a book: you either see it as a box with something inside and start looking for what it signifies. . . Or there's the other way: you see the book as a little nonsignifying machine. This second way of reading is intensive: something comes through or it doesn't. There's nothing to explain, nothing to understand, nothing to interpret. *It's like plugging into an electric circuit* (Deleuze, 1990, as quoted in Roy 2003, pp. 177–178; Roy's emphasis).

Roy concludes by affirming the generativity of Deleuzoguattarian experimentation in curriculum inquiry:

Deleuzian concepts are 'little nonsignifying machines'; it is a mistake to try to see them in terms of mere signification, for the signifier leads us back to Oedipalized or controlled territory. Instead, what we must do is plug into these concepts or tiny 'circuits' that have a destratifying charge of their own in any encounter, and see what they do mutually, if they do anything. We must experiment with them incessantly, and find out how, and if, they operate on our intensities and how the intensities operate on them. For Deleuze, a book is a tool box. . . where the tools become, one by one, the very parts they were supposed to be working on, not as in an assimilation but a disjunctive synthesis, for they produce a difference and never the Same (p. 178).

St. Pierre (2013) has similar advice for beginning researchers: "My advice to my students who read Deleuze and find his work exhilarating is to 'read everything you can by and about Deleuze and plug his machine into yours. Then tell us what happened'" (p. 226).

Roy borrows and deploys a number of Deleuzean concepts to theorize and address the stress-ridden lives of teachers, with particular reference to *nomad* and *rhizome*, both of which center around the notion of *becoming*. Sellers and Gough (2010) also put these concepts to work in their performance of "an assemblage of empathetic

responses to thinking (differently) with Deleuze in educational philosophy and curriculum inquiry” (p. 589). They demonstrate how Deleuze and Guattari have inspired them (individually and collaboratively) in distinctive ways:

One of us (Gough) has produced a series of narrative experiments that foregrounds the generativity of ‘rhizosemiotic play’ (catalyzed by intertextual readings of selected fictions) in writing educational philosophy and theory, and the other (Sellers) has produced a doctoral thesis through processes of ‘rhizo-imaginary’ ‘picturing’ towards immanent and emergent curriculum theorizing. . . [Our] collaborations have resulted in co-authored works [. . .] but what we value in sharing our individual thinking ~ writing is not so much what brings us together but what sends us out-ontowards as we each see the ordinary extra-ordinarily.

In this essay we inter-picture-and-text-ually extemporise our genealogical and generative work with Deleuzian conceptual creations. . . with a view to moving readers beyond merely using select metaphors. . . (e.g., nomadism, rhizome, lines of flight, smooth and striated spaces). We deliberately distance ourselves from those who ‘use’ Deleuze by appropriating metaphors that were never intended as metaphors, preferring to work towards generating discourses ~ practices that challenge such a deployment of complexity-reducing Deleuzian figurations. Rather, we. . . demonstrate how thinking with Deleuze produces previously unthought questions, practices and knowledges that, we propose, are resonant with those of *art brut*, the term Deleuze uses to characterize what he calls his kind of philosophy: ‘more naïve . . . not the most profound but the most innocent’ (pp. 589–590; these authors frequently use the ~ [tilde] to signal a conjoining of co-implicated notions in what they call complicity – thinking that is complicit with writing and vice versa).

Deleuzoguattarian Deconstruction (and Reinvigoration) of *Currere*

When the North American curriculum field underwent its so-called reconceptualization in the late 1960s and early 1970s (comprehensively documented by Pinar et al. 1995) its salient features included exploring curriculum via eclectic traditions, such as psychoanalysis, phenomenology, and existentialism. One form of curriculum inquiry popularized by William Pinar and Madeleine Grumet (influential leaders of the reconceptualist movement), became known as

currere, a form of autobiographical curriculum theory informed by phenomenology:

Grumet cited *currere* as a method and theory of curriculum which escapes the epistemological traps of mainstream social science and educational research. *Currere* focuses on the educational experience of the individual, as reported by the individual. Rather than working to quantify behaviors to describe their surface interaction or to establish causality, *currere* seeks to describe what the individual subject him or herself makes of these behaviors (Pinar et al. 1995, p. 414).

During the 1990s, Gough subjected *currere* to poststructuralist critique by deploying science fiction texts to “diffract” stories of educational inquiry generated by *currere*. During the 2000s he drew more heavily on Deleuze and Guattari to deconstruct a wider range of educational questions, problems, and issues in areas such as cyborg pedagogy, science and environmental education, and the internationalization of curriculum studies, coining the term “rhizosemiotic play” to name his approach to Deleuzoguattarian imaginative inquiry. One of Gough’s students, Warren Sellers, advanced this approach in a thesis that foregrounds Sellers’ proclivity and talent for expressing himself through “picturing” rather than words (the works referred to in this paragraph are cited in Sellers and Gough 2010).

Recent Affirmations of Deleuzoguattarian Scholarship

Scholars such as Jason Wallin (2011) and Alistair Stewart (2015) are taking *currere* in new directions informed by Deleuzoguattarian thinking. Wallin deploys the concept of *currere* to mark a departure from Pinar and Grumet’s autobiographical method:

This book is not autobiographical, nor is it oriented toward reflection. It is however, a work that approaches *currere* as a concept for pedagogical thinking. It is a work that departs, not merely from quantitative fetters, but from phenomenology, structuralism, and the dominant image of life that Deleuze and Guattari call ‘Oesdipal’ (p. ix).

As with Gough’s tactical uses of science fiction, and Sellers’ uses of visual art, Wallin is

interested in “explicating the power of the arts to liberate productive desires and potentials” (p. x). He draws from numerous artistic innovations (including improvisational jazz, graphic novels, video games, and the films of Todd Haynes, Jim Jarmusch, and Quentin Tarantino) “to consider the material ways in which the ‘arts’ have opposed power, affirmed difference, and dehabituated normalized discourses” (pp. x-xi).

Stewart (2015) creates the concept *rhizocurrere* to chart his efforts to develop place-responsive outdoor environmental education. As the term implies, *rhizocurrere* brings *currere* together with the Deleuzoguattarian *rhizome*. Stewart responds to invitations from Deleuze, Guattari, and Pinar to experiment by adapting their ideas to create a concept that draws attention to relationships between his pedagogical and curriculum research and the contexts that have shaped his life and work. In keeping with the Deleuzoguattarian concept of order-words, Stewart’s central question is not “what is *rhizocurrere*?” but rather “how does/could *rhizocurrere* work?” and “what does/might *rhizocurrere* allow me to do?” (p. 1169).

David R. Cole’s (2011) *Educational Life-forms: Deleuzian Teaching and Learning Practice* offers another recent affirmation of Deleuzoguattarian scholarship. Gough’s foreword to this text commends Cole for writing “in the spirit of Deleuze’s encouragement for ‘writing to bring something to life, to free life from where it’s trapped, to trace lines of flight.’ This is evident in Cole’s deployment of the Deleuze-inspired figuration of ‘educational life-forms’ in contrast to the more conventional academic tactic of arguing through metaphor” (p. x). Gough’s foreword emphasizes that “the notion of figurations, in contrast to the representational function of metaphors, is crucial to Deleuze’s notion of a conceptually charged use of the imagination” and that “figurations are performative images that can be inhabited, condensed maps of contestable worlds and bumps that make us swerve from literal-mindedness” (Cole 2011, p. xi; the quoted passages here are contractions of quotations from other authors cited in the foreword). Cole (2011) introduces educational life-forms as follows:

What is an educational life-form? The first section of the title is an example of conceptual creativity that has been derived from Deleuze. Of course, in schools, colleges and universities, there is an abundance of life. However, this isn’t the point of the life-forms. The primary implication of the life-forms and their use in this book is that one should think through the questions about life with respect to education. For example, the ways in which teacher training happens can be a matter of machinic functioning in terms of responding to the demands of government and schools for teachers. . . . The second implication of the educational life-forms is that one may perform conjunctive synthesis. This is a type of experimentation with form, which also encourages one to think (about life). . . . The heterogeneity of potential educational life-forms is parallel to the diversity one finds in the natural world, and involves bringing concrete examples to bear on learning styles and education (pp. 2–3).

Cole then assembles two highly diverse systems (bacteria and hurricanes) as an incitement to imagine a new educational life form, the bacteria-hurricane machine:

This machine may give rise to pedagogy that explores the facts and mechanisms of bacteria and hurricanes, and a resulting wealth of mathematical and scientific ideas. On the other side of knowledge work, the bacteria-hurricane machine could be an inspiration for artistic, musical and written work. What would a bacteria-hurricane machine look like? What would it sound like? How could we describe its action? What would happen if a bacteria-hurricane machine appears in the world? The conjunctive synthesis of the bacteria-hurricane machine therefore stimulates the educational unconscious and the desire of the learners to explore this new realm of knowledge. Deleuzian teaching and learning practice encourages inter and crossdisciplinary work, knowledge structures are opened up, and systems are analysed with the prospect of sustained thought and developing competency in virtual manipulation (pp. 7–8).

It is hoped that the works cited and sampled above demonstrate and affirm that Deleuze and Guattari’s concepts constitute a durable life-form in curriculum inquiry.

Deleuze and Guattari in Early Childhood Education

Liselott Mariett Olsson
Södertörn University, Flemingsberg/Stockholm,
Sweden

Introduction: A Thought Created Through Encounters in ECE

Deleuze and Guattari were at their most active during the 1970s and 1980s in France, and they

were part of a generation of thinkers that also included Michel Foucault (1926–1984), Jacques Derrida (1930–2004), and Jean-François Lyotard (1924–1998) among others. The intellectual milieu in France was at this time dominated by structuralist thought, but Deleuze and Guattari challenged structuralism as it was expressed in linguistics, anthropology, and psychoanalysis through redefining structures as open ended and unstable. For them, a first condition of any structure is something that always deviates and escapes from it. This concerns linguistic structures but also society as a whole and even the history of philosophy (Deleuze and Guattari 1984, 2004). The Western history of philosophy has always been preoccupied with defining conditions for thought and organizing a place for systematic thinking (Spindler 2006). For Deleuze and Guattari, this equals not thinking at all, as thought conditioned in that way is marked by recognition and representation and obeys the laws of that which we already know:

“Everybody” knows very well that in fact men think rarely, and more often under the impulse of a shock than in the excitement of a taste for thinking. (Deleuze 1994, p. 132)

Deleuze and Guattari’s philosophy breaks with this tradition of thought in that it transfers the status of thought as superior, interior, and grounded in pre-given conditions to a thought that lays out its ground as it proceeds and that is continuously created through encounters with the outside:

Something in the world forces us to think. This something is an object not of recognition but of a fundamental *encounter*. (Deleuze 1994, p. 139; original emphasis)

This reworking of philosophy and thought presents a number of philosophical problems that connect to the contemporary context in ECE, of which three will be mentioned in this introduction:

Structure and the Social Field

One important connection between Deleuze and Guattari’s philosophy and the field of ECE

concerns how structure is conceived of and worked with in the social field:

I would say for my own part: a society, a social field does not contradict itself, but what is primary is, that it is leaking. (Deleuze 1994, p. 61; my translation)

If a first condition of any structure is that it is leaking, it is possible to study and work in the social field beyond predetermined positions and habitual ways of thinking, talking, and doing. This makes it difficult to talk about Deleuze and Guattari as “poststructuralists” as they consider also the linguistic system as leaking and do not give the linguistic sign the status as bearer of signification (Deleuze and Guattari 2004). The sign here has the status as *a-signifying*, and signification has been replaced by function, the only important thing being how linguistic signs work. Rather than identifying (linguistic) discourses, research here needs to focus on the nondiscursive, non-interpretative potentialities inherent in any structure.

Thought Created Through Encounters and the Relation of Research and Practice

A second connection with the field of ECE concerns the relation of research and practice and the role of the researcher. When the conditions for thinking are changed in the way described above, research and the researcher can no longer be considered as distanced from practice. Rather, they are immediately part of that which is studied and contribute in *creating* the empirical material. This is where “transcendental empiricism” gets its sense, as it indicates a certain devaluation of the already conditioned thought and promotes a new relation between research and practice. There is an important difference between the words “transcendence” and “transcendental.” Transcendence refers to the highest organizing principle, i.e., thought that organizes empirical experiences, but transcendental is that which comes before the consciously thinking subject, expressed in the quote below as “a-subjective consciousness”:

What is a transcendental field? It can be distinguished from experience in that it doesn’t refer to an object or belong to a subject (empirical representation). It appears therefore as a pure stream of a-subjective consciousness, a pre-reflexive

impersonal consciousness, a qualitative duration of consciousness without a self. (Deleuze 2001, p. 25)

Transcendental empiricism is a “wilder kind of empiricism” that does not let consciousness designate the subject as capable of thinking of itself and the world as objects. Researchers that are normally accustomed to delivering consciousness-raising critique of practice from a distance are here invited to fully admit science’s productiveness and inventiveness and to engage in the co-creation and coproduction in, of, and with “the empirical.”

Becoming and the Image of the Child

This conceiving of the subject also leads to a third connection concerning the image of the child in ECE research and practice. The field has during later decades developed into paying more attention to children’s voices and rights. For instance, through the rise of the new sociology of childhood (Qvortrup 1994) where children’s participation was an important question as well as the child’s right to “being” rather than “becoming adult,” Deleuze and Guattari’s philosophy invites to a slightly different image of the child. Following their thinking, it is exactly “being” that is contested in favor of “becoming.” However, and most importantly, this is a becoming that is different than the becoming-same of a child becoming adult. The becoming of a child is here a becoming without a purpose and goal (Deleuze and Guattari 2004). This is where the notion of a “neomaterial” philosophy gets its sense. In fact, reality and being are within this philosophy closer to a realist than an idealist perspective, although and importantly realist with a twist. *Neomaterial* here indicates that physical and material reality harbors more than one dimension. A virtual dimension continuously actualizes itself into the actual dimension that we hold for real:

A life contains only virtuals. It is made up of virtualities, events, singularities. What we call virtual is not something that lacks reality but something that is engaged in a process of actualization following the plane that gives it its particular reality. (Deleuze 2001, p. 31)

For research and practice in ECE, this line of thinking brings the possibility of multiple and transforming images of the child. The child that we see every day is obviously a real child, but through the idea of a virtual dimension perpetually actualizing itself, the child is also a continuously becoming child.

According to Zourabichvili (2003), since Deleuze and Guattari's thinking and concepts create a rupture with the history of philosophy, they need to be approached through their own grammar and logic. Otherwise, their particular logical consistency will be misinterpreted, and the potential of the philosophical work will be overlooked. It is also important to remind of the context where it was created: the aftermaths of May 1968, a context of political activism where intellectual work was intimately connected to social and political everyday life. The use of Deleuze and Guattari needs to take this political activism into account. Otherwise, it runs this risk of depoliticizing this body of work or maybe even uncritically runs the errands of contemporary political governing that also claims "creativity" and "thinking outside the box." There is great need for further research here that tentatively and with carefulness explores this thinking in ECE. Below follows the tracing of a trajectory – from *Anti-Oedipus* (1984) to *A Thousand Plateaus* (2004), via *The Logic of Sense* (2004) and over to *What Is Philosophy?* (1994) – that makes visible some possible connections with political activist work in ECE.

Desire as Production of Real – The Turn of the Gaze of Lack in ECE

The book *Anti-Oedipus: Capitalism and Schizophrenia* was originally published in French in 1972. The book can be understood as a long and meticulous critique of psychoanalysis' structural overinterpretation of the subject. Psychoanalysis is in the book credited with the creative move of having invented the psyche, the unconscious, and desire as driving force, but the critique delivered by Deleuze and Guattari concerns desire and the subject being read and understood through the features of lack of a fantasized object:

To a certain degree, the traditional logic of desire is all wrong from the very outset: from the very first step that the Platonic logic of desire forces us to take, making us choose between *production* and *acquisition*. From the moment that we place desire on the side of acquisition, we make desire an idealistic (...) conception, which causes us to look upon it as primarily a lack: a lack of an object, a lack of the real object. (Deleuze and Guattari 1984, p. 25; original emphasis)

Even though the field of early childhood education is a different field than the field of psychoanalysis, the features of lack and acquisition are quite prevalent within these practices, not the least through the way that the field has picked up theories coming from developmental psychology, where the child has got its position and predetermined development and where everything that does not fit in to this predefined scheme is considered in need of being redressed. Even within so-called "child-centered pedagogies" desiring-repression is evident, as they talk about departing from children's "needs." When desire is equaled with "need," it inevitably takes on the features of lack and acquisition: you need to acquire something because you do not have it. As an alternative, Deleuze and Guattari propose to see desire as "pure production of real" (1984, pp. 26–49). They try to turn around the logic that says that institutions, such as preschools, respond to preexisting needs embedded within children. From their perspective, desire must be politicized: children become "needy" since institutions capture, reduce, and tame their desires. Moreover, the alternative definition of desire as "pure production of real" proposes that institutions also have the choice to reverse this gaze of lack and instead become curious of and "latch onto" children's desires, making it possible for them to influence and produce real life in preschool in new ways.

In *A Thousand Plateaus: Capitalism and Schizophrenia* (2004), desire is given a more complex setting. In an interview with Claire Parnet (Boutang 2004), Deleuze talks about how *Anti-Oedipus* was poorly received and how desire was misunderstood as "spontanéisme." The sequel *A Thousand Plateaus* can therefore be understood as an attempt to deal with this misunderstanding through connecting desire with language.

Language is here treated in a different way than within linguistics; in fact, this book is possible to read as a long battle with linguistics. Linguistics accord language nonspatial and temporal features that make it seemingly independent of materiality. This lack of materiality creates somewhat imperialist pretensions of language as encompassing all other strata. But at the same time language is underestimated in that it also contains a pragmatic and becoming dimension (Deleuze and Guattari 2004, p. 70).

In *A Thousand Plateaus*, desire is connected to language through describing how it works in assemblages where bodies and language go through a rhythmic act of re- and deterritorialization and breaking out of and settling into territories, the contours and frames of a particular assemblage (Grosz 2008).

It seems important for the field of ECE to take this move into account. A “spontanéiste” idea of desire might lead to a romanticized image of the child, promoting an “anything goes” pedagogy consisting in simply following children’s desires and interests, as if they were purely “emotional” and disconnected from the territory offered to them through the educational setting.

Today, the situation is even more complex as contemporary governing has changed face into neo-liberal attempts to govern, no longer only through externally imposed rules but through the very modulation of desire and internal self-regulation (Massumi 2003). There is a great risk, then, that the trying to “latch onto” children’s desires uncritically joins this movement. Here is opened a great potential for further research that tries to simultaneously navigate critique and creation of alternatives.

Production of Sense: A Tool for Dealing with Learning and Knowledge in ECE

In contemporary educational contexts, young children’s learning is highlighted, but as Deleuze says, it seems that this is only said “because it is the fashion” (Deleuze 1994, p. 166). Education has developed from being considered the key to well-being of nations and individuals into a global and result-oriented competition between nations

within an economic logic. Knowledge is treated in a simplified way where truth is taken for granted and questions and problems taken as givens with equally given, “correct,” and true answers and solutions. Or knowledge is being treated in the abovementioned “spontanéiste” and relativist way through a romanticized image of the child and the proposal of an “anything goes pedagogy.” The writings in *The Logic of Sense* (2004) might here be useful for navigating questions of learning and knowledge in ECE. In this book, as well as in the book *Difference and Repetition* (1994), Deleuze proposes a notion of sense as *continuously produced* in everyday events. Truth is here seen not as given but as a deserved effect of the sense being produced. This is expressed in how solutions to problems come forward in a proportional relation to the sense of the problem:

A solution always has the truth it deserves according to the problem to which it is a response, and the problem always has the solution it deserves in proportion to its sense. (Deleuze 1994, p. 159)

This has got implications for the way learning and knowledge is conceived in ECE. If truth is seen as an effect of sense and if a solution is proportional in relation to sense, children’s answers and solutions no longer need to be judged from the point of view of truth or falseness. Instead, there can be engagement in how children – departing from the very sense-production at stake – will *construct* problems and *formulate* questions. Here, there is great potential for developing more research. This alternative way of conceiving of sense-production might help educationalists to approach content in pedagogical practice in a stringent and still open way. This might also make possible – in a time and place where focus is only on results and questions of what and how – the opening up for and the reclaiming of questions of *why*, that is, questions of the sense and meaningfulness of ECE research and practice.

Plane of Immanence: Transdisciplinary Political Experimentation in ECE

The sense and meaningfulness of ECE need to be continuously rethought maybe today more than

ever as the force and immediate workings of neo-liberal governing invade and hijack efforts in the field. Here, the notion of “a plane of immanence” might be of help in order to make possible a transdisciplinary political experimentation in ECE. The plane of immanence is not to be understood as a concept. Rather, it is on the plane of immanence where concepts are created. The plane of immanence is the equivalence of the earlier mentioned transcendental field where consciousness no longer functions:

The transcendent is not the transcendental. Were it not for consciousness, the transcendental field would be defined as a pure plane of immanence, because it eludes all transcendence of the subject and of the object. (Deleuze 2001, p. 26)

In *What Is Philosophy?* (1994), Deleuze and Guattari show how this plane is in itself transforming and connective and how it is on this plane that continuous actualizations of the virtual dimension of reality are taking place. In this book, the authors claim that society is threatened by an increasingly poor and uncreative thought. As an answer to this threat of a thought with low vitality, leading only to the expression of fashion-like opinions, Deleuze and Guattari draw up the contours of the three disciplines, philosophy, science, and art, as originally and equally creative disciplines with the common task to experiment together and work against simple opinion and for a creative thought. Philosophy, science, and art harbor the possibility to do this through their respective and complementing ways of relating to the virtual. The virtual is, as earlier said by Deleuze and Guattari, defined as an added dimension to reality where things “spring up only to disappear immediately (...) an infinite speed of birth and disappearance” (1994, p. 118). In order to reach a creative thought, philosophy tries to retain this speed and give to the virtual a consistency specific to it through *creating concepts*. Science tries to slow down this speed in order to gain a reference that will actualize the virtual through incessantly *creating functions*. Finally, art tries to gain compositions where finite speed never stops restoring infinite speed within the virtual by *creating sensations*. The *continuous creation* of concepts, functions, and sensations

binds the three disciplines together and makes them capable of working against simple opinion and for a creative thought. Even though each discipline has its proper means to do this, they also sometimes exchange roles and functions, such as when artists create sensations of concepts or functions. Furthermore, in order for concepts, functions, and sensations to not fall back into simple opinions, the disciplines need to find themselves in a constant reinvention of themselves. This is where they all need the confrontation with a non-philosophy, a nonscience, and a non-art, not as negation or opposition, but as a producer of disciplines in continuous becoming. This might present one of the greatest challenges for ECE and for education in general today: to approach educational questions in a transdisciplinary way in order to reclaim a vital and creative thought and to become forceful political actors. Here, there are great possibilities for future ECE research in the intersection of philosophy, science, and art.

Introduction

The collaboration between French academic philosopher Gilles Deleuze and psychoanalyst/activist Felix Guattari resulted in the production of a wealth of material beginning in the 1970s and lasting until the early 1990s. Although their collaboration produced a synergy that would result in the proliferation of a range of powerful concepts that continue to resonate with architects, painters, writers, philosophers, social scientists, activists, and psychoanalysts, and educators, among others, their initial meeting and subsequent collaboration was the result of fortuitous circumstances in

France during the late 1960s. It was the kind of political singularity that marked 1968 in Paris, France, where diverse sectors of society began to collaborate and work together in previously unforeseen ways that provided the opening in which Deleuze's academic and Guattari's clinical/political paths were first to cross. Furthermore, it was the events of 1968 political in Paris, France, that served as the fuel for their first theoretical collaboration resulting in the publication of *Anti-Oedipus: Capitalism and Schizophrenia* (1983) – a book that is, more than anything else, a work of political philosophy. Together, with Anti-Oedipus, they would write four books in total including *Kafka: A Minor Literature* (1986), *A Thousand Plateaus: Volume II of Capitalism and Schizophrenia* (1987), and *What is Philosophy* (1994). Although these books deal with a number of different topics, what unifies them as a collaborative project while also setting them apart from Deleuze's previous philosophical works is their overt political intentions.

Although the subject of education is rarely directly discussed in any of their work, there is a vast untapped potential to utilize the work of Deleuze and Guattari to help politicize the subject of education for teachers, students, and educational theorists and researchers in new ways (Carlin and Wallin 2014). To speak of education in the work of Deleuze and Guattari is necessarily to consider it within the context of the political spirit that brought them together. Consequently, a politics of education conceived alongside the work of Deleuze and Guattari emerges out of a consideration of pedagogy within the prevailing political themes found throughout their collaborations: the concepts of *capture* and *control* that describe how contemporary forms of exploitation operate within the context of neoliberal capitalism and a corresponding conceptual invention in the form of the *war machine* that they mobilize against such exploitation.

Capture and Control

For Deleuze and Guattari, it is act of capture that composes the primary function of State societies

and the corresponding concept of control that describes how the expanded presence of the State makes its way into the interior of the socius to work in the service of new forms of capitalist accumulation. For Deleuze and Guattari, the State operates by way of the dual workings of the ruler who binds, serving as the source through which the multitude become adherent to the One, and the jurist who codifies through the imposition of treaties, laws, and contracts (1987, p. 351). This dual aspect of the State is brought to bear on labor power and the conditions for the creation of labor power in order to produce surplus value. The State, in this case, becomes “the sole and transcendent public-property owner, the master of surplus or stock, the organiser of large-scale works (surplus labour), the source of public functions and bureaucracy” (1987, p. 428).

In its neoliberal form, capitalism has become informalized, making its way into all aspects of everyday life and disengaging itself from its previous reliance on governmental institutions to orchestrate the accumulation of surplus value. What this indicates for Deleuze and Guattari is that the State is no longer solely oriented toward capturing those territories existing externally to the socius – in the form of what Marx famously called primitive accumulation – but it is now oriented toward the capture of internal territories (where primitive accumulation is also now directed inward). As capital has become social capital, the extraction of surplus value no longer pertains to the work place, but to the entire interior of the socius, including the capture of affects, desires, and emotional energies. In other words, instead of conceiving of these changes as an indication that the State has become superfluous, Deleuze and Guattari argue that the new expansive properties of capitalist accumulation simply make the State indistinguishable from society. In the face of the construction of new pathways to extract profit from previously unforeseen internal territories, the State has not been abolished, but merely internalized.

As the State has been internalized in contemporary capitalism, and forms of potential accumulation have expanded, social control for Deleuze

and Guattari has taken on new importance. As a result both schooling and education have also assumed new roles. No longer does the institution of schooling serve as the specific sites from which one goes to complete the necessary training to be a productive citizen, but an institution that has completely adopted the corporate model. Under these circumstances, students are no longer confined to fulfill their necessary training, but set “free” to actively and continuously participate in consumption, the production of surplus value, and never ending forms of training and education necessary for both. Put differently, a person does not go through life being molded in different institutional arenas at different times of their life. They are no longer solely expected to be in school from ages 5 to 22, but now must be a part of constant modulation and, in the case of schooling, in education mode at all times. Education ceases to exist as a specific and separate institution where one goes and finally finishes to move onto other disciplinary spheres. Instead, educational training begins to meld into the home and workplace – all places that are conceived as potential sites for the extraction of surplus value. This corporate model of education demands a subject that is always already in a process of seeking out new tastes, sensibilities, and images (Carlin and Wallin, p. xxii).

Consider one of the dominant mantras found in educational rhetoric today, that of “life-long learning.” This mantra not only saturates educational institutions, but serves a crucial role in opening up the possibility for the advancement of continuing education. Such education is oriented toward the creation of flexible entrepreneurs who are not only prepared to move from one job to the next, but also to participate in the kinds of never-ending training necessary to effectively seek out new means and pathways to extract profit from the internal territories now being opened up through the State/society/capital nexus and the full adoption of the corporate model into every sphere of life (Carlin and Wallin 2014). In accordance with advancement of continual education and lifelong learning, increasing forms of testing are utilized to create statistical and representative formulations

of students as a way to measure their current and potential to become such entrepreneurs. Within this kind of conception of schooling, students are also being prepared to participate in educational training for the rest of their lives – where their success as students becomes increasingly dependent upon the maintenance of their own educational incompleteness. To be a completed subject in education – where one would formally finish schooling and education – would stand in direct confrontation with the neoliberal requisite of lifelong training to ensure that students are a continual source and generator of surplus value for their entire lives.

The internalization of the State not only affects the contemporary model and conceptualization of schooling but also the way that students think. It is what Deleuze and Guattari (1987) refer to as “State thought” that describes an authoritarian, arboreal model of thinking tied to rationality and foundationalism that serves to tether all thought expression to previous categories and concepts. Such thought does not act to defend the State, but “. . . is already in conformity with a model that it borrows from the State apparatus, and which defines for it goals and paths, conduits, channels, organs, an entire organon” (1987, p. 374). In other words, State thought is the acceptable form of thought that is constituent of the kind of transcendent, binary forms of thought that eliminate multiplicity and difference in favor of the One. Opposed to the authoritarianism of State thought, Deleuze and Guattari propose rhizomatic thought that eschews arboreal essences and growth in favor of the wildness and unpredictability of the root system of grass.

This neoliberal context requires a kind of political intervention that is up to the task of trying to escape the impasses of the regulation, cliché, and predetermination of how one can and should be educated, as well as how one can think. For Deleuze and Guattari, what needs to be done is the creation of new tools – both conceptual and otherwise – that might allow us to extricate a genuine form of education, schooling, and thought from the State of education today.

The War Machine

One of the key concepts that they mobilized in their political philosophy against such exploitation was that of “the war machine” – an idea indebted to the work of French anthropologist and anarchist Pierre Clastres who spent years working with the Guayaki, Guarani, and Yanomami tribes in Paraguay, Venezuela, and Brazil in the 1960s and 1970s. As a result of his ethnographic work, Clastres famously proclaimed that “primitive societies” are essentially societies without a State (1987, 2010). This was not the result of situating these tribes on the bottom rung of some teleological rendering of world history. By contrast, Clastres recognized that “primitive” peoples had created the kind of sociocultural mechanisms necessary in order to avoid the emergence and imposition of the State.

When the State is perfected, power resides in the hands of the few, society is organized hierarchically, the “legitimate” use of violence is monopolized, and those with power have the ability to forcibly extract profit/riches from the rest of the populace. Such perfection culminates in the emergence of the despot. While this ideal State has been enacted to varying degrees of success, despotism has served as the “horizon” of all that the State desires to be. Those who have managed to avoid such Ur-aspects of stateliness did so not as a result of an accident, luck, or an “undeveloped” form of socioeconomic organization that predated the advent of capitalism and the formation of the nation State but rather through a form of sociocultural organization intentionally designed to prohibit, or limit the possibility of, the formation of the State. Why have “primitive” peoples organized themselves around deterring the formation of the State? It is precisely because they are well aware of the consequences of its emergence.

For Clastres, the way that primitive societies avoid the State and the kind of capture and control imminent to *Stateliness* is through the enactment of war – sometimes real and sometimes symbolic in nature. This may seem counterintuitive. However, for Clastres war stands against sovereignty

and the associated consolidation of wealth and power in the way that it acts as a form of rupture and flight from such capture. It is not as if primitive societies do not have leaders. Only that war enacted by warriors is on the side of the *socius* in order that leaders, while granted great respect and prestige, lack any ability to consolidate power in the hands of the few. Specifically, it was the mechanism of war that served this function, ensuring both the “dispersal” and “segmentarity” of groups so that neither the consolidation of power in the hands of the few nor the reification of institutional life was possible (1987, p. 357).

For Deleuze and Guattari, Clastres’ work and inherent critique of the teleological advancement of the world that culminates in the formation of the State and its associated institutions allowed them to consider the concept of war as a source from which to avoid capture. Similarly, it was through the work of Clastres that Deleuze and Guattari advanced the argument that the State is not a recent invention nor a product of a particular form of economic development as many Marxists have advocated, but rather a social formation that has always been in existence. Like Clastres, Deleuze and Guattari’s concept of the *war machine* is not a reference to an armed and militarized group that engages in acts of violence. In other words, the primary object of the war machine is never war but another kind of violence that allows for escape, or what Deleuze and Guattari refer to as “lines of flight” from the kinds of capture and control that define the State’s influence over the social field. Only when the State appropriates the war machine does it come to exist as a military institution – incorporated into the administrative and bureaucratic spatiotemporal formation that pertains to the State. Set against such control over the social field, the war machine for Deleuze and Guattari is that which mutates and defines all forms of creativity. Such mutations can be found individually or through group formations and can refer to either material practices or acts of thought: to art, education, ecology, economy, philosophy, or politics. It is a concept that refers to variable relations to war itself, innumerable creative potentialities, and as such to multiple meanings (1987, p. 422).

Deleuze and Guattari develop this concept through a reference to spatiality and movement. In terms of space, it is the *smooth* space of the war machine that enables lines of flight from the grooved, predetermined, *striated* space of the State that dictates how one is to live a life, think, and be educated. In terms of movement, the war machine is always intimately connected to what they call the nomad. However, the nomad is not necessarily a reference to movement but a reference to escape from the sedentarism engendered by striated space that allows for the formation of the State in all of its variants. Ultimately, for Deleuze and Guattari, the war machine is “irreducible to the State apparatus. . . outside its sovereignty and prior to its law: it comes from elsewhere” (1987, p. 352) and as such the nomad is always, in movement or in stillness, that which is able to remain external to the apparatus of the State.

An Education of the Outside

As always external to the State, the war machine stands in opposition to the coded plane that functions alongside the State/society/capital nexus. To participate in a war machine is to participate in an uncoded radical form of difference that evades the establishment of any kind of stable identities. The State can appear in an unlimited number of ways within the context of schools including hierarchical centralized authority inherent in administrative, teacher, student, and parent/teacher group formation, as well as the kinds of transcendent, identitarian, and representative forms of thought that constitute legitimate knowledge throughout all levels of schooling. However, the war machine can similarly appear in unlimited social formations, but is always oriented toward undermining and/or escaping from the bureaucratic, administrative, and spatiotemporal formations of control that dominate any level of education where the State has become internalized. The war machine is the absolute outside to the State. For Deleuze and Guattari, “(T)he State’s pretension to be a world order, and to root man. The war machine’s relation to an outside is not another ‘model’; it is an

assemblage that makes thought itself nomadic” (1987, p. 24).

As a result, to enact the war machine in education is to subvert the consolidation of power in any of its forms while creating the eventual (sociocultural, organizational, and political) mechanisms that will inhibit its appearance again. To create an education of the outside is to extract a genuine form of education, schooling, and thought from the State of things as it pertains to the corporate model in operation today. An education inspired by the war machine would coincide with a kind of combat that would help us to evade the known through problematizing our habitual comportment and thought as it relates to how one is to teach, how one is to learn, and how an education is to proceed. Education inspired by the war machine would instigate a kind of “unlearning” that would work to disrupt common sense and constituted knowledge, as well as the methods currently in operation in schools today that determine the ways that bodies are organized and groups are formed.

Conclusion

For Deleuze and Guattari, concepts such as “the war machine” should be conceived of as tools. In this sense, the conceptual tool should not be mobilized in order to label our experiences in education so that multiplicity of difference is obscured through the application of the concept, but to create new connectivities that illuminate difference and complexity in previously unforeseen ways. In other words, we should not consider the use of a concept such as the *war machine* in terms of the way that we can bring it to bear on pedagogical or educational environments. To utilize concepts as Deleuze and Guattari intended is not to use concepts in a representative manner – and here we should think of the term *representative* in its full political significance where the multitude is represented by and subsequently falls under the control of the One. We can utilize terms such as “the war machine” and others found in the work of Deleuze and Guattari as ways to create new connections within and between fields, ideas, and situations, so that we

might open up the potential to extract a genuine form of education from the preestablished realm of pedagogy in operation today. In the politics of education inherent in the work of Deleuze and Guattari, we are reminded that education bound to prior categories of expression is antithetical to the promise of pedagogy itself. In other words, by containing pedagogical experiences within a series of predetermined conceptual formations – by always confining pedagogy to what has already been determined – the possibility of learning itself becomes foreclosed. As such, an engagement with Deleuze and Guattari would generate a politics of education oriented toward the disruption of the State in all of its forms.

Introduction

Gilles Deleuze (1925–1995) provides an integrated theorization of learning without having written specifically on education. He was a philosopher who worked for the majority of his life as an intellectual and university academic. Deleuze was propelled into the public eye in 1972, after the success of his first collaborative work with Félix Guattari, called *Anti-Oedipus*. He did not write a book on learning, so one must piece together his ideas on learning from comments interspersed from within the oeuvre. Despite this apparent lack of direct information and analysis of learning, Deleuze's ideas have gained traction in many educational and creative circles (Cole 2011). Perhaps this is because Deleuze provides what he described as “a conceptual toolbox” (Deleuze 1980, p. 17), which can be readily applied to education in terms of a philosophical framing and as a theoretical base that resists dogmatism and encourages the novel and imaginative (re) creation of theory and practice. In this entry, this conceptual toolbox does not represent a *free-for-all* in terms of an *anything-goes* learning and educational theory, but, on the contrary, the Deleuzian toolbox is in many ways deliberately hard to accept and necessarily challenging to put into action.

Deleuze and Learning

Deleuze's most direct statements with respect to learning come in his book on *Difference and Repetition*. In it, he says: “. . . ‘learning’ always takes place in and through the unconscious, thereby establishing the bond of a profound complicity between nature and mind” (Deleuze 1994, p. 165). This is the last sentence of a paragraph on problematic ideas and an explanation of how one learns to swim with respect to the idea of the sea. Deleuze's argument is that one learns to swim in the sea not by opposing the sea in dialectical fashion, nor by deconstructing it, still less by imposing a person's will upon the waves in a

mythological, Cnut style. Following the philosophy of Deleuze, one learns through an “apprenticeship with signs.” Further, education is “amorous yet fatal” (Deleuze 1994, p. 23); in the case of swimming in the sea, the swimmer is able to cope with the waves and the currents of the seas, not by copying or repeating their existence and forms or through any processes of familiarization or thoughts about being a “natural sea swimmer,” but by becoming attuned over time to the way in which one has to swim in the seas in order to survive and to stay afloat. Deleuze (1994, p. 23) states that one learns from teachers who say “do with me” and not from teachers who say “do as I do”; in other words, learning is a necessarily reciprocating and relational process – and includes elements of non-relation, which makes questioning of accepted knowledge an imperative and working together communally around knowledge problems essential. Inna Semetsky (2009) has suggested that Deleuze's approach to learning solves Plato's paradox in *Meno* about learning, in that the production of new knowledge according to Socrates is merely the function of memory or recollection. Plato surmised that all knowledge is locked in the unconscious, so that one doesn't learn at all, but recollects what one already knows through the recognition of truths through argumentation and Socratic dialogue. Deleuze (1994) turns this formulation around in *Difference and Repetition*, in that the unconscious is no longer a passive receiver of knowledge and the memory the active disseminator of knowledge. Contrariwise, the unconscious does profoundly synthetic and positive, i.e., paradoxically conscious, work according to Deleuze, through the clashing of affect and the playing with chaotic material processes through, for example, creative experimentation. The unconscious is in the Deleuzian frame a creative and vital cauldron of new thought. However, to get to this new vision of the unconscious as the place where learning fundamentally happens, one has to first attend to issues concerning philosophy and the image of thought that it has projected over time.

Philosophy and Learning

Deleuze executed a number of philosophical studies during his career, specifically focusing on the philosophies of David Hume, Friedrich Nietzsche, Henri Bergson, Benedictus de Spinoza, Immanuel Kant, Michel Foucault, and Gottfried Leibniz. These works by Deleuze on other philosophers do not constitute a history of philosophy, nor do they provide straightforward commentaries on the philosophy of these named thinkers. Rather, Deleuze executed these studies to come up with “new thought,” in order to question the classical or accepted image of thought and to ultimately produce a philosophical system that promotes learning through the unconscious and nature and questions knowledge as given. In some ways, every philosophy produces an “image of thought,” even Deleuze’s project to come up with a new image of thought and to return the thought of the philosophers to learning. In this context, Deleuze’s project is to enable an image of thought that may be infinitely divisible or possible to be differentiated *in itself*, until thought and learning themselves become apparent to the thinker and learner. In terms of Western metaphysics, the dominant and most far-reaching “image of thought” comes from Plato in terms of what constitutes metaphysics. Deleuze (1994) could be positioned as one of many thinkers who have tried to overcome Plato’s image of thought, yet the approach that he takes in *Difference and Repetition* is distinguished from many others in that the eight postulates that are proposed in order to question the philosophically dogmatic image of thought suggest an ultimate escape route from representation as the basis for metaphysics in general into learning per se and not only with reference to Plato.

The eight postulates from *Difference and Repetition* (see below) constitute a framing of the dogmatic image of thought that specifically attempts to dismantle the manner in which thought has been created and recreated more recently through thinkers such as Kant and Heidegger. According to Deleuze, Kant and

Heidegger create dogmatic images of thought because their systems for thought must be understood before any new thought can happen. The eight postulates signify a means to fully examine such images of thoughts and to allow for unthoughts, non-thoughts, and, importantly given the context of this entry, learning through the unconscious and nature to make its way into a *new arena for thought*. One could argue that everything that Deleuze writes after the “Image of Thought” section of *Difference and Repetition* during his career relates to these postulates in some way and is an attempt to create thought without an image that makes philosophy more democratic and fully open to novel reinterpretation. One could argue that this proposition is perhaps most fully realized in the rhizomatics of *A Thousand Plateaus*, because the “rhizomic text” and multiple conceptual elements of *A Thousand Plateaus* attempt to fully engage with the notion of immanence, including how immanence relates to time, power, and the fluctuations of everyday life (e.g., Cole 2013). Immanence is for Deleuze the great leveling concept, which makes new thought accessible beyond the philosophical specialism, seen, for example, in Kant or Heidegger, and learning in the moment becomes apparent. The eight Deleuzian postulates that a new image of thought and any consequent learning from Deleuze rest upon are as follows.

The eight postulates: from Difference and Repetition (Deleuze 1994, p. 167):

1. The Postulate of the Principle or the *Cogitatio Natural Universalis*: the good will of the thinker and the good nature of thought.
2. The Postulate of the Ideal or Common Sense: common sense as the *concordia facultatum* and good sense as the distribution that guarantees this accord.
3. The Postulate of the Model or of Recognition: recognition presupposes the harmonious exercise of the faculties on an object that is supposedly *identical* for each of these faculties and the consequent possibility of *error* in the distribution when one faculty confuses one of its

objects with a different object of another faculty.

4. The Postulate of the Element or Representation: difference is subordinated to the complementary dimensions of the *same* and the *similar* and the *analogous* and the *opposed*.
5. The Postulate of the Negative or of Error: error expresses everything that can go *wrong* in thought, but only as a product of *external* mechanisms.
6. The Postulate of the Logical Function or the Proposition: designation or denotation [theory of reference] is taken to be the locus of truth, sense of being no more than a neutralized double or the infinite doubling of the proposition.
7. The Postulate of the Modality or Solutions: problems are materially traced from propositions or are formally defined by the possibility of them being solved.
8. The Postulate of the End or the Result or the Postulate of Knowledge: the subordination of learning to knowledge and of culture [or *paideia*] to method.

These eight postulates from *Difference and Repetition* work on the level of problematizing and questioning the image of thought. The first two postulates refer to the ways in which philosophers have made implicit agreements between themselves about what thought is and what thought should be. These agreements might jeopardize learning according to Deleuze. Likewise, postulates three and four refer to the ways in which philosophical systems have produced models and represented the image of thought as the “self-same.” The philosophical systems of Kant and Heidegger are good examples of these types of thinking models or modes of representation that require thinking through their tenets before any new thought or learning can happen. Postulate five is a reference to the Hegelian system of thought that prioritizes negation in thought to create difference (Somers-Hall 2012), therefore making learning dependent on the negation of, for example, the thought of nature and the unconscious, which is exactly what Deleuze wants learning to connect with. Postulates six and

seven refer to propositional logic and how the definition of the image of thought in these terms can produce thought that excludes problems that do not fit with the strictures of propositional logic, i.e., irrational and illogical thought. Learning itself would also be trammled along the lines of propositional logic according to these postulates. Postulate eight refers to the ways in which knowledge can dominate learning and create methods that intercede and take away from the force of culture. Deleuze wants to return thought to learning and culture and not to a set of predefined methods or sets of instructions that can take away from the impact and veracity of new thought.

One needs to systematically go through the postulates from *Difference and Repetition* to arrive at the last postulate, number eight, that directly relates to learning and is the starting point for a new metaphysics of learning from Deleuze that disavows representation in thought, i.e., gets back to learning *qua* learning and not the thought of learning. Deleuze (1994, p. 167) in *Difference and Repetition* immediately qualifies and questions the eight postulates and says that they function best in silence. How can one make sense of the notion that the thought that escapes the dogmatic image of thought through the eight postulates returns one to a state of learning, and helps to reverse the traditionally philosophical or classical “image of thought” and its accompanying dogmas, and yet is born “in thought” (Deleuze 1994, p. 167)? In terms of philosophical analysis, the genesis of “the image of thought” and the consequent critique of the image of thought through the eight postulates come from Deleuze’s earlier (1983) book *Nietzsche and Philosophy*.

Here, Deleuze begins his sustained move away from the tenets of representative thought and looks to understand how Nietzschean forces may power thought, such as the contrast between reactive (moral) forces and life-affirming forces. One could argue that according to Nietzsche, paramount among the forces of reaction and affirmation is the force of now, which congeals everyday forces from a contemporary perspective that may work to corrupt and subjugate the mobility of

thought. In Nietzschean terms, the power of the philosopher is derived from the ability to think (and learn) outside of the prejudices, clichés, and banalities contained in the social forces of the contemporary situation. This is why Nietzsche refined his writing technique to such an extent in order to come up with a new form of aphoristic writing that attempted to pierce the bubble of contemporary values and thought and that could execute a powerful critique on the image of thought connected to “now” and to reconnect thinking with learning. In consequence, Nietzsche teaches us to be wary of contemporary fashion and to exercise critical and affective energies when approaching thought, which might turn out to be merely reactive or responding to moral, narrow-minded, reproductive, or power-based dictates. This is one of the reasons why Deleuze qualifies his eight postulates with silence and with their birth “in thought,” which means they are precisely designed to escape the clamor of the contemporary moment and in order to connect to learning, to the unconscious, and to nature. The concern to make Deleuze’s postulates receptive to and part of an exploration of the unconscious predominantly comes from his examination of the formulation of the drives for thinking in Nietzsche and in the writing processes of Proust in *Proust and Signs*.

In *Proust and Signs*, the section on “the image of thought” concerns the ways in which the thinking of the philosopher can miss out on specific types of knowledge, aesthetic sensitivities, the learning that comes from the heart, and the thought processes contained in Proust’s writing style. Proust’s *In Search of Lost Time* sets up a wholly different image of thought to the philosophical image of thought, and it is through understanding the processes contained in the writing of this book that one is able to go beyond the rational, historic, and communal assumptions of the philosophers as listed by the eight postulates. Deleuze’s argument in *Proust and Signs* is that the writing of Proust adds to the endeavors and insights of the philosophers and that Proust’s work is philosophical, precisely because it out-manuevers what Plato calls “simultaneously contrary perceptions” (Deleuze 2000, p. 101). In

other words, Proust has the ability to write around such perceptions, and to make art of them, or to touch upon “sensations common to 2 places, to 2 moments” (ibid.). Proust is a Deleuzian exemplar of a writer able to deal with involuntary signs in a creative way and in a manner which forces us to think and learn.

Parallel to Nietzsche, who is a thinker out of time (as exemplified by Zarathustra), Proust is a thinker of time. Proust creates an image of thought that does not represent the tropes of now, but gets inside the mechanisms of time to encounter the fleeting effects, an apprenticeship in signs, and the delayed action in thought and learning. In Proust’s writing, obvious and scenic or exterior imagery is substituted for the time dimension to produce what Deleuze and Guattari (1988, p. 380) describe in *A Thousand Plateaus* in a parallel manner and with reference to nomadism, as “(a)ll of thought is a becoming, a double becoming, rather than the attribute of a Subject and the representation of a whole.” Deleuze, Proust, and Nietzsche allow for and give mobility to thought through their art and hence show what the image of thought is through learning, the unconscious, and nature. As has been noted above and in contrast to, for example, Kant and Heidegger, whose intellectual comprehension requires steadfast study of the structural aspects of *their* thought before new thought can happen, i.e., with respect to being, the faculties of thought and the possibility of experience, according to the approach of Deleuze, Proust and Nietzsche, have injected freedom into the construction of thought and into the consequent image of thought with respect to how new thought and learning happen.

However, if one accepts Deleuze’s notion of thinking and learning and how it proceeds empirically, one should be able to configure these processes in the world in some way. This point comes about not because Deleuze’s transcendental empiricism as he names this approach in *Difference and Repetition* requires any extrasensory or universal validity, but because the ways in which one can make sense of the eight postulates, the learning, and the image of thought that they refer to must relate in some way to practice. This is because it is in practice that the Deleuzian

postulates can reach their tipping points and any breakthrough in the image of thought toward learning can be realized, i.e., immanently and in tandem with a concern for power.

Conclusion

If one compares Deleuze's ideas on learning with, for example, John Hattie's (2009) book called *Visible Learning*, which is widely cited in education, one could state that in contrast, Deleuze's thoughts on learning describe a form of "invisible learning." Deleuze designates pre-personal, fluctuating grounds for learning that can seem to be very different from the systematic analysis of the factors and strategies of/for learning as analyzed statistically by Hattie (2009). However, if one digs deeper into the two approaches to learning represented by Deleuze and Hattie, one can realize that the two positions are not so far removed. Deleuze is not adverse to scientific and mathematical explanation of phenomena; in fact he deploys such means frequently in his writing with respect to, for example, "singularities" and "the virtual," yet Deleuze always brings back such explanations to thinking, creativity, and social problems.

The difference in the two approaches to learning is that Hattie (2009) stops at the "effect size" of every strategy or factor in learning from the 800 meta-analyses that are appropriated, which enables a ranking of the effect sizes. In contrast, Deleuze has latterly analyzed philosophy, literature, cinema, capitalism, science, and history to come up with an extended notion of learning as questioning the image of thought in these contexts. Certainly, one could argue that Deleuze's notion of learning requires evidence-based studies of the type that Hattie (2009) has used in his ranking of the effect sizes of factors and strategies to enhance learning. This is perhaps a task for future educators and future education researchers that have been influenced by the philosophy of Deleuze to attend to, as they work together to change mainstream educational provision. Deleuze's philosophical and intellectual approach to learning has the capacity to radically alter the course of educational practice beyond the short term and to make a difference

in terms of the measurable "effect sizes" as calculated by Hattie (2009).

Introduction

Deleuze argued that we should look to the *practice* of mathematics for how to think about life

more generally, advocating for a “problematics” that was strongly modeled on particular kinds of mathematical activity (Duffy 2013). The differential calculus and other kinds of mathematics are used by Deleuze to develop a philosophy of difference and repetition. He takes up mathematical concepts from analysis, topology, and algebra, citing the work of mathematicians Gottfried Leibniz, Joseph-Louis Lagrange, Richard Dedekind, Emile Galois, Henri Poincaré, Józef Wroński, and post-Kantian philosophers who wrote about mathematics, such as Salomon Maimon, Jean Bordas-Demoulin, Albert Lautman, and Jean Cavaillès.

In this entry, I focus on the role that mathematics plays in his political ontology, as developed in *Difference and Repetition* (1994) and show how these ideas were further elaborated in later work, including *A Thousand Plateaus: Capitalism and Schizophrenia* (1987), coauthored with Felix Guattari.

Problematics

Following Albert Lautman, Deleuze (1994) suggests that mathematics operates according to a problematics where “a problem has three aspects: its difference in kind from solutions; its transcendence in relation to the solutions that it engenders on the basis of its own determinant conditions; and its immanence in solutions which cover it, the problem being the better resolved the more *it is* determined.” (Deleuze 1994, p. 179). Mathematical theories – like the differential calculus – are solutions to these generative problems. Thus specific mathematical theories – whatever they may be – belong to mathematics, but they are also *examples* of a “mathesis universalis” insofar as there is a universal problematics (Deleuze 1994, p. 181).

In other words, mathematics is not metaphorical for Deleuze, but is rather an excellent example for studying how this generative problematics is at work in the world (Duffy 2006). The differential calculus is *one* example of a problematics, and Deleuze also points to other areas of mathematics as perhaps even better examples, in particular the group theory of Abel and Galois. Indeed, the

development of abstract algebra in the nineteenth century, based on the work of Abel and Galois, is declared by Deleuze to be “a radical reversal in the problem-solution relation, a more considerable revolution than the Copernican . . . For as Georges Verriest remarks, the group of an equation does not characterize at a given moment what we know about its roots, but the objectivity of what we do not know about them” (Deleuze 1994, p. 180).

But despite this gesture toward algebra, it is the differential calculus that Deleuze revisits again and again in various texts, suggesting that it gets as close as we have ever been to a differential ontology of the virtual. He synthesizes three previous commentaries on the significance of the calculus, combining them into a comprehensive theory of how the virtual and the actual are enmeshed. First, Bordas-Demoulin suggests that dx is the “problematic idea” and the “undetermined,” second Maimon stresses how there is a reciprocal determination dy/dx at work rather than an individual determination, and third Wroński emphasizes the “complete determination” that is achieved in mathematical integration, where integration entails the creation of a function that is not *entailed* in the summation and thus captures the *genetic power* of differentiation. These three key aspects of Deleuze’s philosophy of difference (the undetermined, reciprocal determination, the potential) are derived from the calculus and are crucial for how Deleuze moves away from Kant’s “conditions” of experience, toward a theory of how the new comes into the world.

Deleuze (1994) aligns the threesome of the “undetermined, the determinable, and the determined” with “quantitability, qualitability, and potentiality” (p. 176). Of note is the fact that these are all “abilities” or capacities that inhere in the world and that “quantitability” describes not the standard use of quantity (as that which counts and measures) but a virtual dimension of matter. The differential calculus synthesizes this three-pronged approach and becomes a powerful problematics, and by studying this problematics, we can begin to imagine how problematics might flourish elsewhere in other fields, and we can seek the “differential and genetic element” that

fuels all of becoming (Deleuze 1999, p. 51). In *The Fold*, Deleuze (1993) will draw extensively on Leibniz and “Baroque mathematics” to argue for a differential folding universe, bringing together the differential calculus with a monadology. The differential relation (dy/dx) is the “quantitative determination” of this relational ontology of forces, be they molecular or affective, which fold the fabric of life in varying ways (de Freitas 2016). We must, says Deleuze, follow the *intrinsic quantitative relationships* that are within the qualitative “unity” of becoming. The mathematical concept of the differential is that indeterminate vibration or virtual dimension that always troubles the fixity of any quantity or object ($x + dx$).

Axiomatics

In a mathematical problematics, concepts quiver with indeterminacy. The square, for instance, *is* the material process of quadrature; the circle *is* the differential forces that sustain or produce or determine it. Any curve determined by an equation or static definition can be reconsidered as a dynamic machine – comprising the differential threesome of “undetermined, the determinable, and the determined.” The visible circle drawn on a blackboard is simply the effect of a series of differentials of higher and higher degree. Deleuze will compare the general equation of a circle $x^2 + y^2 - R = 0$ with the differential equation $ydy + xdx = 0$ which captures “the universal of the circumference or of the corresponding function.” (Deleuze 1988, p. 171). This differential equation quivers with its universality and its indeterminacy. A problematics is thus an approach to mathematics that reanimates the figures and equations of mathematics and sets them in motion, embracing the event nature of concepts, so that we might resist the tendency to imagine transcendent references for them.

Deleuze and Guattari (1987) develop this idea further and show how there has always been at least two currents in the history of mathematics, on the one hand problematics and on the other axiomatics. They compare State-sanctioned or

“royal” or “major” mathematics with other lineages of mathematics, which they call “nomadic” or “minor.” They describe how influential State-sanctioned traditions like the Bourbaki were intent on eliminating the dynamic and “less rigorous” mathematics of the infinitesimal calculus. Historians often describe this period as the “rigorization of mathematics,” but Deleuze and Guattari (1987) will counter this narrative with an account of how state mathematics became a kind of *axiomatics* (versus *problematics*) that denied the event nature of mathematical activity (Smith 2005, 2006). State mathematics, according to this account, imposed static rules on notions such as “becoming, heterogeneity, infinitesimal, passage to the limit, [and] continuous variation” (Deleuze and Guattari 1987, p. 363).

In the context of education, this contrast between axiomatics and problematics finds a parallel in the mathematics curriculum, in the tension between the logical and ontological dimensions of mathematical activity. Mathematics curriculum is built around an axiomatic image of mathematics. That image rests on a logicist bias that crept into the curriculum and came to dominate our understanding of mathematics. Here the term *logicism* refers to the philosophical position that mathematics can and should be reduced to logic. Of course mathematics entails (or can entail) some degree of logical deduction, but there is more to the activity of mathematics than logic and axiomatic deduction. Proof is never only deductive or inductive, but is also generative and constructive. The history of mathematics shows us how particular mathematical practices have been silenced and demoted and how the coupling of mathematics with logic became entrenched in the State-sanctioned discipline (see Hacking 2014, for excellent insights on this historical development).

Deleuze and Guattari (1987) will define state mathematics as the axiomatic deduction of properties from a set of given concepts. In contrast, minor mathematics refers to a more speculative and “less rigorous” mathematical practice that is always tamed by the epsilon-delta police of state mathematics. (Minor mathematics also refers to that side of mathematics that entails making

monsters and paradoxes, a topic to which I return at the end of this entry.) In pragmatic terms, this means that minor or nomadic mathematics dwells in the mathematical concept *as an event*, while state mathematics treats the concept as a representation of essence.

Intensity and Number

Deleuze draws extensively on the French philosopher Henri Bergson to develop his ideas on differentiation: “We will see that one of Bergson’s most curious ideas is that difference itself has a number, a virtual number, a sort of numbering number.” (Deleuze 1999, p. 44). The numbering number refers to the virtual intensity of number – that is, it refers to number before it is tamed by extension. Although we associate quantity with the act of measuring and partitioning extension, Deleuze uses the concept of the numbering number to get at the “intensive” source by which number mutates and resists current measures. Reclaiming number as implicated in his ontology is crucial if Deleuze, following Bergson, is to develop a radically new philosophy of difference. For if quantity is conceived within the usual quantitative paradigm, then it is always *external* to difference – an external metric or count imposed on the qualitative. But why should quantity be the one concept that escapes potentiality? Why shouldn’t quantity also have an unscripted future and virtual dimension? This is precisely why Deleuze (1994) suggests that there is a “quantitability” that inheres in the virtual, a kind of inexact calculation whereby “the real in the world [is] understood in terms of fractional or even incommensurable numbers” (p. 222).

Deleuze (1994) argues that there is a virtual and actual side to number and that these two “sides” correspond to intensive and extensive relations: “every number is originally *intensive and vectorial* in so far as it implies a difference of quantity which cannot properly be cancelled, but *extensive and scalar* in so far as it cancels this difference on another plane that it creates and on which it is explicated” (p. 322, *my emphasis*). A number that cannot be “properly canceled” is

a number that escapes the operators that operate on it – a number for which one cannot find an inverse that might cancel it. This is an ontological claim about the potentiality of number, a claim that forces us to rethink what terms like scalar, vectorial, and dynamic might mean in this case. According to Deleuze, number partakes in an *intensive* quantity before it is tamed and encapsulated in an *extensive* quantity. This first intensive number is not yet calibrated in terms of a fixed unit and not yet a number we can use as a counter, *and yet this virtual number is as much a part of matter as extensive magnitude*. Intensity is a crucial concept for Deleuze precisely because it points to how quantity or quanta cannot be reduced to the concept of extension, but none the less inheres in matter. Note that this is not a platonic philosophy of mathematics (in which number is an abstract ideal that transcends matter), but a philosophy of immanence, where *number is implicated in a vibrant and indeterminate matter*. De Freitas (2013) and de Freitas and Sinclair (2014) explore the implications of this ontology in relation to mathematical activity of all kinds, from recreational to expert.

Ordinality

For Deleuze (1994), the concept of ordinality, rather than cardinality, is associated with the intensity of number: “Even the simplest type of number displays this duality: natural numbers are first ordinal, in other words, originally intensive. Cardinal numbers result from these and are presented as the explication of the ordinal” (Deleuze 1994, p. 322). He aims to rescue and reuse the concept of ordinality from being only the repetition of the same unit or the fixed ordering of a set. The ordinal for Deleuze taps into the genetic differential that is the engine of his intensive ontology. Ordinality is thus a broad concept, more complex than what we tend to assume, because it plugs into the virtual depth of the “intensive spatium” (Deleuze 1994, p. 323).

Deleuze and Guattari (1987) will further develop this idea of ordinality and link it to Bergson’s notion of the “numbering number”:

The Numbering Number, in other words, autonomous, arithmetic, organization, implies neither a superior degree of abstraction nor very large quantities . . . These numbers appear as soon as one distributes something in space, instead of dividing up space or distributing space itself . . . *The number is no longer a means of counting or measuring but of moving: it is the number itself that moves through space . . . The numbering number is rhythmic, not harmonic* (Deleuze and Guattari 1987, pp. 389–390, *our emphasis*).

When number becomes “the numbering number,” it becomes a “mobile occupant,” “ambulant fire,” and the “directional number” all of which are different ways to think differently about *ordinality*. Deleuze and Guattari (1987) suggest that if we grasp or pursue the intensive nature of ordinality, we can begin to imagine how number might not only serve the control state, but instead achieve a *mobile occupying* without *whole* number counting or striating of space. It would be this other kind of smooth space where creativity (and anarchy!) can thrive. State striation will be an approach to number that is “exclusively cardinal in character,” while the “ordinal, directional, nomadic, articulated number, the numbering number” produces degrees of freedom in an unstriated (or non-partitioned) space (Deleuze and Guattari 1987, p. 535). This number is ordinal in terms of how it brings forth the unscripted new, with each “count,” rather than establishing the size or metric of a set.

Deleuze and Guattari (1987) use the distinction between ordinal and cardinal to discuss the political mis/uses of number, showing how different uses of number reflect very different kinds of politics. Their work looks for how State-sanctioned mathematics loses touch with the dynamism and intensity of the ordinal number. Ordinality comes to be associated with a nomadic arithmetic that mobilizes the unruly power of number to bring forth the new and to curl number into itself in varying ways. In other words, nomadic arithmetic has an ambulant, mobile dimension that contrasts with “geometry,” where geometry is the practice of measuring or *striating* a static space. If the ordinal can tap into its power and plug into the intensive potentiality of the spatium (and not simply the repetition of the same), then there is possibility of creative counter-uses of number.

Revolutionary Arithmetic

Geometry and arithmetic reflect very different political relationships with territory and the distribution of power. Arithmetic always marks a certain nomadic relation to territory, because “algebra and arithmetic arise in a strongly nomad influenced world” (p. 388). They argue that arithmetic has a revolutionary potential precisely because it troubles the striating line of enclosure and control, the geometric line that measures and contains. While geometric measurement lends itself to the control of space, there is also an “independence or autonomy of the [arithmetic] Number” that subverts this kind of spatial striation (Deleuze and Guattari 1987, p. 389).

One might – quite legitimately – ask how on earth it is possible to pursue an arithmetic in this mad revolutionary way. It’s hard to imagine what sort of “revolutionary” arithmetic Deleuze and Guattari have in mind, since arithmetic seems like arithmetic, no matter how you slice it. But it is possible to look into the history of mathematics and find revolutionary kinds of numbers that shook the foundation of society. In particular, the infinitesimal played such a role, being banned by the Jesuits in the 1600s for its “blasphemous” nature and outlawed in schools across Europe (de Freitas [in press](#)). For Deleuze and Guattari, the infinitesimal was one example of a radical new way of calculating, a new kind of number that produced a rich array of new mathematical ideas and techniques. But most importantly, the early use of the infinitesimal was *paradoxical*, and it was these various paradoxes that Torricelli would deploy so brilliantly in all his calculations.

The point is that the history of number supplies examples of how number can, on occasion, plug into its intensive dimension and become paradoxical (rather than orthodox). But what about today? What might the “numbering number” be today? It would have to be something that was fought over, contested, debated, denied existence, and something that seemed to shake the very foundations of mathematics. And it has to, in some way, leverage the paradoxical and the intensity of the virtual. It would have to delve into the depth of ordinal intensity and plug into the virtual potentiality of

number more generally. Although such ground-moving moments in mathematics are rare, the ramifications are world changing (Alexander 2014). But perhaps there is always a volcanic rumbling in even the simplest use of number. Might there be a way to sense this rumbling in recreational mathematics, or everyday mathematics, be it practical and accurate or off-the-wall and incoherent? Might we wish to encourage more mad paradoxical arithmetic in classrooms so that the numbering number might erupt in new revolutionary garb? For Deleuze and Guattari (1987), ordinality is a generative force, a zigzagging line of flight that can furnish paradoxical but creative misuses of number. By breaking up the orthodoxy around number sense and revealing the bias toward the cardinality concept, we can begin to imagine otherwise.

Chance and Dynamic Systems

Not only does Deleuze's work help us think differently about the spatiotemporal materiality of mathematical concepts like number, it also puts forward a new commingling of chance and algorithm well suited to our digital times. Deleuze turns to the mathematics of chance and dynamic systems in order to propose new ways of thinking interaction and sociality. He also turns to topology as a powerful way of reconceiving political relationships of proximity and circulation, building on the foundation of the differential calculus. He uses key topological concepts – manifolds, curvature, inflection points, and singularities – to discuss the way that socioeconomic forces move across an event, contracting into singular points of power (singularities) that structure the behavior of those around them (see especially Deleuze 1993 and later work with Guattari).

Deleuze (1988) claims that counting is not only an act of determination, but must actually entail a kind of dice throw. For instance, as I lean in to count the faces on a polyhedron, I move from face to face (one, two, three, etc.) and this activity entails my affirming not just the individuated number of faces, but *all of numeracy*, because numeracy is continuously thread into the folding

fabric of life. Counting is both a blocking of that continuity (performing a particular count and number) and an affirmation of it (feeling the flow of an absolute infinite count – all of indeterminate number) (Deleuze 1988). Deleuze inserts chance and multiplicity into each and every individual count, but also, and perhaps more controversially, he claims that number is precisely how chance thrives:

The thrown dice form the number which brings the dice throw back. Bringing the dice throw back the number puts chance back into the fire, it maintains the fire which reheats chance. This is because number is being, unity and necessity, but unity affirmed of multiplicity as such, being which is affirmed of becoming as such. Number is present in chance in the same way as being and law are present in becoming (Deleuze 2006, pp. 29–30).

There is a reciprocity between number and chance, insofar as the “thrown dice” forms or determines a number, but the number sustains the element of chance within it. This is what subverts statistical prediction and at the same time invites new speculative methods that deploy the quantitative. Deleuze is offering us a new vision of the relationship between the qualitative and the quantitative, a new way of thinking about the role of chance in our lives. He suggests that this new relationship demands a “qualitative probabilism” (Deleuze 1988).

This suggestion may sound too well suited to our new digital culture of probabilistic reasoning and calculated publics. But this idea of the count as that which *affirms all of chance at once* is precisely why his theory is so relevant to our computational times. We need to ask how one might think the quantitative in research methods and social theory without it being just a statistical striating of space (de Freitas et al, [in press](#)). Can we imagine a future where the quantitative in education research would offer creative and ethical adventures in thought? Could such a future reconfigure the relationship between the qualitative and the quantitative? How can social theory put the quantitative to work without it simply serving the control society? The numbering number is a kind of arithmetic that is “distributing number in space, instead of dividing up space,”

and thus it evokes a moving number, a number that is scattered and demolished, reassembled with chance, and thrown back into the fire. It is in this way that number becomes the “mobile occupant,” “directional number,” and “the ambulant fire.” This emphasis on number as *ambulant fire* in Deleuze’s books with Guattari raises the specter of a fractal geometry of singularities.

Singularities and Fractal Monsters

In *A thousand Plateaus*, in the chapter on smooth and striated space, Deleuze and Guattari (1987) mention the Koch snowflake and the Sierpensky sponge as examples of smooth spaces insofar as these kinds of figures pursue a fractional dimension, somewhere between line and plane or between plane and solid. Any space with a fractional dimension escapes conventional measures and is “the index of a properly directional space.” In other words, the dimensionality of a smooth space is determined by that which moves through it, rather than by some magnitude of containment. These fractal examples show how ordinality becomes inflected by chance, recursion, and singularity. They also point to a new kind of computational becoming, for it is through the iterative mobile calculating of a space-filling fractal that a line can fill a plane without ceasing to be a line.

For Deleuze and Guattari (1987), this is a crucial aspect of creative and dynamic spaces – that they do not have “a dimension higher than that which moves through it or is inscribed in it.” (p. 488). This is how number resists the containment of the cardinal, which is always the count of *how many* rather than the *flow* of the ordinal. Indeed, a condition for smooth space will be a mobile ordinal numbering, *occupying* without whole number counting. Fractals pursue this recursive directional number – indeed, monstrous calculations of this kind are another example of how calculation becomes monstrous and revolutionary (de Freitas 2015). Massumi (1992) declares “The plane of life itself . . . is a space-filling fractal of infinite dimension.” (p. 23). The

monstrous nondifferentiable but continuous Koch snowflake fractal, for example, proliferates singularities as it repeats and expands. Deleuze and Guattari use this example to describe a fractal image of life, to show how calculation can be *machinic but non-axiomatic*. They use fractals as monstrous calculating devices that transform the concept of measure and multiplicity.

The concept of the fractal became increasingly important in Guattari’s writing on chaosmosis, where various processes of fractalization figure prominently in thinking the sociopolitical subject. Fractals occupy fractional dimensional spaces and thereby break with conventions regarding space and embodiment. A fractal recombinant subject no longer abides by the dominant image of the organism and phenomenological subjectivity. Chance and algorithm commingle in the fractal subject, mutating and folding universe in new ways. A fractal subjectivity will find very different ways of becoming in the contemporary world. We can see that the differential calculus remains pivotal in the later work of Deleuze and Guattari, but it is the concept of the singularity that takes on more significance, doing the *structuring* work that is needed for fractal folding and recombinant becoming. Deleuze and Guattari (1987) tap into the infinitesimal as the calculating engine of their ontology, a means of differentiating the mathematical continuum (achieving the necessary “reciprocal presupposition” of our “common matter” (pp. 108–109)). This later work with Guattari builds on the early work of Deleuze, further developing the mathematical concept of singularity – as the generative and immanent dark precursor to life itself – to address the fractal folds of computational culture and post-quantum subjectivity.

Background

Deleuze was one of the most important French philosophers in the second half of the twentieth century. Deleuze saw his overall philosophical project in terms of overcoming transcendence and dogmatic images of thought that serves to reduce life to sad passions and *ressentiment* and in constructing an ontology of immanence and a thinking from the “outside.” Although Deleuze did not write specifically on a philosophy of religions, his critique of religious ideas makes it clear that he is in general critical of philosophy (Goodchild 2011, p. 139). However, unlike other thinkers who held an oppositional stance in relation to religions, he did not abandon religions but adopted a strategy of assimilating religious ideas that are positive and affirmative. This is why there is a continuous engagement with religious ideas in Deleuze's thought. Deleuze's approach toward religions is to be relevant in contemporary educational settings to the extent that it is marked by transcendence and dogmatic images of thought.

Deleuze and Religion

Deleuze is in general critical of religions. As early as in his first book on Hume, *Empiricism and Subjectivity*, he argued that religions are nothing but a fanciful, illegitimate, and extensive use of the rules of association (Deleuze 1991, p. 76). This attitude toward religions is extended in his

later works such as his last book with Felix Guattari *What is Philosophy?* where he states that religion introduces a form of transcendence that brings sadness (Deleuze and Guattari 1994, p. 43). It is clear that this transcendence did not depart but continues to work in modern institutions. In *Nietzsche and Philosophy*, for example, he lamented the fact that modern philosophy possesses a “theological character” that serves to enslave thought to *ressentiment* and sadness (Deleuze 1983). Just as modern institutions may carry this transcendent structure, modern education may likewise also possess elements of this transcendence. This is the reason why Deleuze warns us against the evolution of educational institutions into forms of continuous control and instantaneous communication, made possible via the introduction of “corporate thinking” into education (Deleuze 1995).

Deleuze’s philosophical project can be regarded in general as a “destructive” one in the sense that it combats against psychological, social, and priestly representations that turn life into a tragedy. In *Anti-Oedipus*, he argues against psychoanalysis’ attempt to resolve the Oedipal complex, because it actually only reinforces the mommy-daddy-me structure, which only serves the colonizing function of capitalism. In *Anti-Oedipus*, Deleuze also calls his philosophical project “schizoanalysis,” thus leaving us no doubt as to the destructive function of their philosophy, that is, to destroy the Oedipal as a dogmatic image of thought which has been imposed on our unconscious (Deleuze and Guattari 2004a, p. 342). This critique of Freud can be extended to the much broader sense of representations, or dogmatic images, that inscribe a regulative law or significance into desire. Deleuze calls this the priestly curse on desire (Deleuze and Guattari 2004b, p. 171).

Although Deleuze was critical of religions in general, it would be a mistake to think that his attitude was simply a negative one. There are also places where he seemed to hold a positive or at least a neutral evaluation with regard to religious ideas. In Deleuze’s engagement with Kant’s thought, for instance, he introduced the possibility of an “atheistic metaphysics” arriving from within

religions itself. Here Deleuze placed an importance on Kant’s theory of God not as an object of belief but as the transcendental ideal of pure reason that makes belief possible in the first place (Kant 1929, pp. 487–495). Kant’s theory is significant because here the idea of God no longer regarded as an object of belief but as a transcendental principle for the constitution of belief as such (Deleuze and Guattari 1984, p. 13). In Deleuze’s study of Bergson’s philosophy in Bergsonism, for instance, Deleuze also utilized Bergson’s theory to point beyond mere philosophical thought to a form of mystical thinking. According to Deleuze, it is the mystic who plays the whole of the universe as its “mystical soul” where philosophers can only consider such a soul “from the outside” (Deleuze 1988, p. 112).

Unlike other thinkers who adopted a more or less oppositional stance toward religions, like Nietzsche, Deleuze adopted a more moderate stance of adapting and modifying religious ideas for his purposes, because he believes that religious concepts, despite their “dogmatic” structures, can also offer us something of value. Thus, many of Deleuze’s philosophical concepts did not ignore but are built on the basis of philosophical ideas that are derived from religious debates in one way or other. For example, Deleuze’s use of the idea of univocity is derived from the philosophy of the thirteenth-century scholastic theologian Duns Scotus (Smith 2012, p. 169). In *Expressionism and Philosophy*, Deleuze also referred to Spinoza’s idea of “infinite substance” which is but a revaluation of the concept of God (Smith 2012, p. 174). In fact, some scholars even go to the extent of saying that the very chipping away at the repressive dimensions of religions produced something of value in thought. Accordingly, Shults has argued that hammering away at theism secretes “atheism” from the very structure of theism itself (Shults 2015, p. 1).

This suggests that for Deleuze the decisive philosophical divide is not simply between religious and the secular spheres but between immanence and transcendence. In the history of Western philosophy, the terms immanence and transcendence can have a number of the different registers depending on the contexts within which

they are placed. In metaphysics, transcendence refers to the belief that there is a transcendent One or Being that stands over and above the Many or beings. This sets up a duality and a hierarchy in which beings become lesser in relation to the One, thus reducing their power to “act.” Deleuze pitted his philosophy against this dualistic and transcendent form of thinking by constructing a philosophy of immanence. In fact, Daniel Smith would even go the extent of saying that Deleuze hunted down transcendence and sought to establish an ontology of immanence throughout his philosophical career (Smith 2003, p. 46). Thus, even though schizoanalysis has a negative function of smashing dogmatic images of thought, it is also important to realize that it possesses a positive function in the sense of mobilizing the “schizzes” of desiring production and the assembling of revolutionary “machines.” Deleuze and Guattari’s project is thus one of destruction and yet also one of affirmation.

Religions and Education

There are a number of works that focus on the significance of Deleuzian thought for education. Some of the most notable ones are Kaustav Roy’s *Teachers in Nomadic Spaces* (2008), Inna Semetsky’s *Nomadic Education* (2008), and William Reynolds and Julie Weaver’s *Expanding Curriculum Theory* (2002) (Carlin and Walin 2015: xxi). This emerging line of scholarship has provoked us to think and act in the sense of creating concepts that for escaping impasses of thought. However, while these works are important, there is a relatively lack of works that focus on the relationship between education and religions. If modern philosophy continues to be pervaded by its “theological” shadow, then likewise modern education can also be possessed by a traditional image of education. This is one where Paolo Freire (1984) might refer to as the “banking” method of education. This is a model in which the teacher occupies a central position in the classroom, in which the teacher occupies a privileged position with regard to the relay of knowledge to unsuspecting and unknowing

students who lack such knowledge. In such an educational model, there is created a situation of transcendence that is reenacted in the classroom, which reproduces the purported knowledge without any real explorations. In such situations, the teacher is placed in a privileged position, while his students are placed in a subordinate position. While this model has proven to be effective in relaying information, it reduces students into a passive position as it encourages absorption of information and not active thinking and learning. There is also much less opportunity when classes are about accepting information rather than explorations which reduces the chances for creativity.

One strategy of overcoming the inherent tendency of education to reduce students to passivity is by reducing the traditional hierarchical relationship between teachers and students in the classroom. Although this structural relationship has come to be accepted to be the norm in education, it is important to make the process of learning more democratic in order to facilitate the learning process and make it more active. The move toward a more student-centered and self-directed learning model in education rather than teacher centered and other directed is reflective of this change. This promises to return the students to their power to “act” and make learning more initiative. In recent years, Semetsky (2005) has called for self-organizing classroom where the hierarchical structure is dissolved, deterritorialization becomes a shared endeavor, and communication becomes transversal (Bonta 2013, p. 66). Cole has already discussed this concept where messages are broadcast to “concurrent independent objects” (Cole 2008, p. 24).

In addition to reducing the hierarchical structure in the classroom which has become prevalent in the educational system, it is also important to look into the motivations of students. Just as there are hierarchical structures in the educational system, there can also be a hierarchical structure in the students’ reliance on extrinsic and “transcendent” goals. Just putting students together in a classroom setting, and reducing the hierarchical position in class, may not necessarily lead to an improvement of learning behaviors. It may lead to some situations where learning becomes

problematic when students lack the necessary motivation to learn. Thus, in terms of motivation, Deleuze's critique of transcendence offers us a warning against an over reliance on extrinsic goals because this is a way of reinstalling transcendence. More importantly, it is about reemphasizing the learning process in education, making it affirmative and positive. Thus, the educational task in question is not in selecting between different extrinsic goals for learning but in affirmation of learning itself. From this perspective, the dominant neoliberal capitalist intrusion into university education obviously presents issues for a form of educational setting in which learning returns to a more privileged position. The drive to produce workers that respond to job training mentality and corporate thinking in fact poses an obstacle to learning itself which is characterized necessarily by a certain degree of creativity and uncertainty.

An important development in terms of a Deleuzian approach to learning and teaching would be the idea of "educational life-forms" (Cole 2011, p. 32). From this perspective, one of education's central aims is about making life stronger and more affirmative. This idea of education life-forms gives educators more options in teaching as it helps to steer them away from merely following the structured programs that enter into our unconscious. With regard to this, there is also a need for a "philosophy of life" that attends to our unconscious. As Cole has stated, Deleuze and Guattari's construction of the unconscious is one that is full of life – the multitude of signs flows, and territories in our minds are able to motivate and discourage us from behaving in certain ways. In this regard, we can no longer imagine that we can abstract ourselves from multitudes of signs that assail us, but with a "semiotics of life," we are able to track and use the energy of the movement of signs in everyday life. This, according to Cole, is what Deleuze and Guattari would call a "schizoanalysis"; this is whereby we learn the semiotics of life so that it enables us to engage in a reading of psychosomatic energies and their dispersal into the social in an affirmative way. This suggests that we are not

to seek to escape the madness of capitalist signs but to harness that madness to our advantage, by expanding the unconscious and then accelerating the consequent imaginative powers. We can use the semiotics of life as educational life-forms in that schizoanalysis and abstract machines are methods for not merely turning away from transcendence but in using the unconscious as a creative and regenerating force. Thus, Deleuzian philosopher offers us a way of harnessing the play of forces in the creative unconscious and using this force to make change happen in the world (Cole 2011, pp. 31–33).

An important element in terms of a Deleuzian approach to education, then, would involve inquiries into religious forms of thinking. Just as Deleuze did not abandon religions but extracted from these religious ideas a form of thought that is affirmative and positive, it is also important for us not to avoid religious ideas as a thing of the past but to examine it carefully and learn from its positive and affirmative aspects. If the main divide is between immanence and transcendence and not between the religious and the secular from a Deleuzian perspective, then an important aspect of education involves examining religious thinking, if only because they continue to pervade our thinking and exercise a hold over us, even over our educational thinking. More importantly, as some scholars such as Shults and Goodchild might say, when we turn toward religious ideas, we may find a core that is either "atheistic" and yet close to the divine (Goodchild 2011, p. 163). Hence, although Deleuze is in general dismissive and critical of religions, we must note that he is not against religions per se but against its transcendental structure, and this structure has continued to operate in modern institutions. Given that this is so, then the task at hand is to hunt down *the transcendental structure in both religions and secular institutions, and that includes the educational system as well*. The question then becomes clear. The problem is not in making education secular or in excluding religions from education but in finding and hunting down the theological and transcendental structures in religions and in our structures of thought. *This suggests that it is also possible to*

find in the religious, elements that are not transcendent but immanent. If this is correct, then turning away from religious thinking runs the risk of dismissing a crucial dimension of thought itself. This is perhaps the reason why although Deleuze has consistently been dismissive of religious ideas, criticizing also the theological ideas that reduce life to sad passions in his more critical studies, he never turns away from the religious.

In terms of resources, there are a number of studies on the intersections between Deleuze's philosophy and religions which may help us review the structures of education. The late Mary Bryden's edited volume of *Deleuze and Religion* (2001) is an important contribution to Deleuzian scholarship in this respect as it contains a number of articles by different scholars reflecting on Deleuze's religious connections. In addition to this volume, there are also others such as Joshua Ramey's *The Hermetic Deleuze* (2012), Christopher Ben Simpson's *Deleuze and Theology* (2012), and Kristien Justaert's *Theology After Deleuze* (2012). More recently, the publication of F. LeRon Shults' *Iconoclastic Theology: Gilles Deleuze and the Secretion of Atheism* (2014) also presents an interesting perspective on Deleuze's attitude toward religions. Deleuze's approach to religious ideas promises to offer us a model for reintroducing critical religious studies as a necessary component in today's secular educational system today. While there are obvious issues in reintroducing religious studies in secular education, the answer does not seem to be to view religious education with suspicion or to abandon it altogether but to extract its affirmative and positive elements for the sake of diversity. Using Deleuzian terminology, the real challenge is in avoiding "dogmatic image of thought" and not abandoning thought altogether.

Conclusion: Education and Neoliberalism

One of the more dominant themes in contemporary educational theory that relate Deleuze's work to education concerns the radical transformation

that educational institutions are undergoing in the age of neoliberalism. Some of the main transformations concern the introduction of new educational technologies and pedagogies, teaching analytics and online MOOCs, etc. which require seemingly endless repetitive administrative tasks which seem to have little to do with education. These constitute new developments in education that together frame and inhabit our educational institutions. In fact, what has become quite controversial in recent years is the way in which university education has become increasingly restrictive, demanding professors track, measure, and report on exactly how their students are learning. This expansion of the teacher's role from mere teaching and research to one of tracking and surveillance is but one of the many changes facing university education in the age of neoliberalism (Bonta 2013, p. 71). Deleuze himself decried the colonization of public post-secondary education in France by the business model that attempted to align curricula to the workplace, essentially transforming universities into training schools (Deleuze and Guattari 1994; Bonta 2013, p. 57). This accounts for Gough's recent statement that university education should be rhizomatic and challenge arborescent models of thought (Gough 2006). While traditional forms of resistance advocated by Paulo Freire now seem outdated, a consideration of Deleuze's approach to religions offers us at least two new insights as to the correct methods of engaging the phenomenon of corporatizing of higher education today. Namely, what is significant in Deleuze and Guattari's works is that these are in some ways expressions of the people's desire (Savat and Thompson 2015) and that it is not always necessary to oppose them because their energies could be recuperated for transformation of the educational landscape (Cole 2011).

Affects; Concepts; Deleuze; Edusemiotics; Ethics; Experience; Logic; Pragmatism; Subjectivity

Introduction

Gilles Deleuze's philosophy has an enormous potential for educational theory, pedagogical practice, and educational research methods and policy. The questions asked by Deleuze (and Deleuze & Guattari in their combined works) address important areas for education such as human subjectivity, experience, logic, language, ethics, creativity, and desire. Deleuze's philosophy is pragmatic and has a surprising affinity with Dewey's educational philosophy with its attention to problematic situations and learning from experience. Deleuze's is the pedagogy of concepts: practical, experimental pedagogy oriented to focusing on problems that defy univocal solutions but represent experimentation with the world and ourselves leading to the creation of new meanings and values. Deleuze's philosophy defies static “being” in lieu of dynamic “becoming” made possible by relations and connections. Rational thought is complemented by non-thought, or unthought and affective, dimension. Philosophical thinking demands the creation of the new. It has strong political implications, reflecting Deleuze's ontology of the virtual, and as such is future oriented, addressing the people yet to come.

Education as inspired by Deleuze's philosophy is untimely: it can transcend the physical present and allows us to envisage multiple opportunities in the open future.

Philosophy as Geography

Within the Continental tradition, Deleuze is an odd figure. His thinking has a surprising affinity with American pragmatic tradition, especially with such figures as Charles S. Peirce and John Dewey (Semetsky 2006). Deleuze's philosophical method has important implications for philosophy of education (and, significantly, in the context of the recently developed new direction, *edusemiotics*). Deleuze and Guattari described philosophy as a geography of reason (geophilosophy) using the metaphors of maps, diagrams, lines, and planes for expressing the nuances of such experiential and experimental thinking that does not reject logic (Semetsky 2013) while denying binary codes. It is linked to the logic of multiplicities which are relational rather than substantial entities; hence, they defy direct representation in conscious thought or by verbal language. Being signs, they indirectly and enigmatically, like hieroglyphs to be deciphered and interpreted, portend and point to something other than themselves. Any given multiplicity always has a middle element as the included third "located" in-between presupposed binary opposites. Such logic (or semiotics) deals a fatal blow to the two terms in a relation that are usually presented as opposing each other in the framework of Cartesian dualism or analytic reason alike.

Deleuze's logic is a-signifying and represents an innovative mix of Peirce's triadic logic of relations and Hjelmslev's linguistics; both perspectives surpassing Saussurean semiology where the unit of analysis is represented by a signifier-signified dyad. Deleuze and Guattari employ Peirce's notion of diagram as a constructive part of relational dynamics. A diagram acts as a semi-otic bridge that functions as a transversal connection crossing over an a-signifying gap by virtue of conjunction "and." Thus, meanings are conferred not by reference to some external object but via

mediation in the relational, or rhizomatic, network whose contours are always changing. Rhizome is a biological metaphor that underscores the living character of signs situated in life and in experience and points to their impending growth and transformation. Deleuze's philosophy makes accent on problematic instances in human experiences, not unlike Dewey's attention to problematic situations, transactions, and revaluations of experience rather than finite solutions.

Rhizome

As embedded in the perplexity of the real-life problematic event, rhizome goes in diverse directions instead of a single path, multiplying its own lines and establishing the plurality of unpredictable connections in the open-ended space of its growth. In short, it lives. It does not represent exactly, but only maps our tentative ways, paths, and movements. Rhizome belongs to the new image of thought that differs from the dogmatic Cartesian paradigm and whose central concept is dynamic *becoming* in contrast to static *being*. As a symbol for unlimited becoming through the multitude of its own inter-connections, rhizome is contrasted with a tree, the latter symbolizing the linear and direct reasoning that establishes a striated model of dichotomous divisions (the tree of Porphyry – *arbor Porphyrii*) as an example of the classificatory system, a hierarchical structure based on discrete definitions that serve as the foundation for rational – demonstrable and certain – knowledge. Yet, modern emphasis on the knowledge economy tends to restrict the process of becoming. Deleuze warns: "One can envisage education . . . giving way to frightful continual training, to continual monitoring of worker-schoolkids or bureaucrat-students. They try to present it as a reform of the school system, but it's really its dismantling" (Deleuze 1995, p. 175).

Experience, Virtual, and Actual

Deleuze's ontology posits the virtual field of becoming that can produce practical effects.

The virtual contains differences, while the actual contains identities; both planes however are real. The virtual expresses itself in different regimes of extralinguistic signs, sometimes at the level of silent, unconscious, discourse (Semetsky 2010) such as involuntary memories or images. Human experience is an extended milieu populated with affective becomings as sign relations. Relations are ontologically prior and external to their terms, thereby invalidating the whole dualistic split expressed in the logical copula "is." Instead, it is the conjunction "and" itself an in-between relation that is ontologically basic. Experience is a-subjective, impersonal, and irreducible to an individual property of the egocentric *Cogito*; rather subjects are constituted in relations by means of intensive individuations via becoming-other within experiential events as folds. Experience is enfolded in the public world and spills over the boundaries of the private Cartesian subject with its isolated instrumental rationality grounded in "I think therefore I am." Experience needs to be transcended – freed from the constraints of common sense – hence infusing empiricism with its transcendental dimension. Deleuze's empiricism is radically transcendental! *Transcendental empiricism* enables an interpretation of signs, signals, and symptoms in practice, thus making sense for the singularity of events. The French word *sens* means at once sense or meaning, and a direction of the course of action that we take in our practical lives depending on the circumstances and contexts of problematic experiences.

Affects and Becomings

The dynamic subject's complex process of formation is described by the intensive capacity to affect and be affected. The production of subjectivity is based on the autonomy of affect as if it were a real being, a force. The forceful, as if physical, intensity of an encounter with an affect marks the passage between the experiential states of the body, which is defined by Deleuze, borrowing from Spinoza, as both physical and mental. Accordingly, the body's power is being changed.

Deleuze specifies the body's power as a capacity to multiply and intensify connections. Conflicting real-life experiences are characterized by their difference; philosophical thinking, then, is conceptualized as the quasi-empirical, practical, mapping of such a difference. By constituting the very content of the movable and moving concepts, the affective dimension is complemented by percepts: "Percepts aren't perceptions, they're packets of sensations and relations that live on independently of whoever experiences them. Affects aren't feelings, they are becomings that spill over beyond whoever lives through them (thereby becoming someone else)" (Deleuze 1995, p. 137). The Deleuzian subject, in a process of becoming-other, is open to an interference of those dynamic affective forces as experiential signs. The transformational pragmatics of experience begins amidst of a "broken chain of affects" (Deleuze and Guattari 1987, p. 9) that reside in life, not just in one's mind.

Pedagogy of Concepts

For Deleuze, the theory of signs is meaningless without the relation between signs and the corresponding apprenticeship in practice. The word *apprendre* in French means to learn, hence apprenticeship. Fixed facts and linguistic truths are not all there is, and we are wrong to believe in truth; rather, there are interpretations: reading the signs of experience. The existential meanings are created as a function of an encounter in the here and now that always already elicits new and differently distributed contexts for which new concepts are to be created. This is what Deleuze called the *pedagogy of concepts*: it is practical learning from experience oriented to real-life problems that defy univocal solutions but represent experimentation with the world and ourselves. Concepts are invented in practice and cannot be reduced to any a priori theoretical judgment. Concepts are not limited to linking the propositions in consciousness: they are (in)corporeal and always express an event as an experiential singularity rather than universal and eternal essence.

The relevance for education is paramount: as Deleuze and Guattari said, “If the three ages of the concept are the encyclopedia, pedagogy, and commercial professional training, only the second can safeguard us from falling from the heights of the first into the disaster of the third” (1994, p. 12). Learning cannot take place as representation: this would be the reproduction of the same, denounced by Deleuze. A novel conceptual understanding of a particular event is not a prerogative of consciousness: mind is extended to the level of the body within nature that embodies the unconscious dimension of experience. It is due to a bond between ourselves and the world that new meanings are created. The unconscious surpasses the Freudian personal unconscious and is “a productive machine ... at once social and desiring” (Deleuze 1995, p. 144). The unconscious is a collective assemblage situated in the material world, usually studied exclusively by physics. Still physics gives way to biology in Deleuze’s corpus, to all matter as radically alive while just manifesting the different degrees of intensity: the frequency of its expression on different planes. Deleuze shares the ancient Hermetic, esoteric, philosophical worldview in this regard.

The Production of Subjectivity

The creation of concepts is impossible without unconscious affects as non-thoughts. As an unconscious *desire* in contrast to one’s conscious *will*, such unthought dimension of experience borders on bodily, as yet a-conceptual, affect. In his move against the Cartesian method, Deleuze speaks of *paideia*, stating that for the Greeks thought was not based on a premeditated decision to think: thinking is motivated by specific – and often shocking – conditions in real experience that will have deterritorialized our habitual patterns of thought and actions. The subtle language of the unconscious, in the process of individuation as the transformation of our habitual attitudes, is to be perceived. Deleuze wants to achieve the means so as to be able to show the imperceptible “hiding” in affects – that is, become capable of bridging the eternal gap, haunting us since Antiquity, between

the sensible and the intelligible. The task of transversal communication is indeed “to bring [the] assemblage of the unconscious to the light of the day, to select the whispering voices, to gather ... secret idioms from which I extract something I call my Self” (Deleuze and Guattari 1987, p. 84): human subjectivity can be (re)created.

Subjectivity of this sort has little to do with a preexisting, fully fledged, and a priori constituted subject. There is no return to the old self, but invention and creation of new possibilities of life by means of unfolding experiential signs. The world is folded – im-plied with possibilities (*le pli* in French means *the fold* in English) that need to be ex-plied. Deleuze points out (citing Henri Michaux, the author of *The Space Within*) that children are born with 22-folds which need to be unfolded in life. In this respect, there cannot be a priori subject; rather, it is a process of the production of subjectivity through work that forces us to frame a new question, to posit a new problem as a function of experience from which we learn. It is life that is our school! Deleuze’s philosophy problematizes the Enlightenment project with its perception of children being blank slates or *tabula rasa*. This perception is a suspect in the philosophy of material encounters, which affect the body’s very power expressed by means of multiplying and intensifying connections as if producing a complex rhizome rather than planting a simple root and, accordingly, raising the degree to which human capacities may be increased. There is no beginning or end. There is no *tabula rasa*: we enter the process in the very middle, in the *intermezzo* laying down rhythms that constitute experiential folds.

The solely rational intentionality as the mark of human consciousness is surpassed by the fold of being as populated by what Deleuze called little, or micro-, perceptions; philosophical thinking is reconceptualized as a cartographic microanalysis devoted to establishing an unconscious psychic mechanism that engenders the perceived in consciousness. It is impossible to achieve new conceptual understanding or to create new meanings and values without becoming aware of the unconscious in our embodied practice. Deleuze’s pedagogy of concepts is inseparable from the

pedagogy of values, the task of which (in contrast to the traditional model of character education focusing on inculcating values if not on direct indoctrination) is *to create* new values oriented to singular modes of existence rather than any absolute commandments. Instead of conforming to fixed moral criteria, the process of subject formation is affective and esthetic, and the system of affects replaces rigid moral codes.

Education as Critical, Clinical, and Creative

Deleuze's philosophical method is nomadic (Semetsky 2008) and implies the reversal of traditional moral education that often reduces values to atomistic facts while forgetting that even Socrates doubted whether virtues could be directly taught. Deleuze (1995) used to identify teaching and learning with the research laboratory as the epitome of novelty, creativity, and multiple becomings that challenge the necessity of some superior educational aims or technical objectives imposed from without and accordingly demanding some transcendent accountability. Rather, it is a developed sense of immanent responsibility oriented first of all to oneself while simultaneously becoming-other. The pedagogy of values is irreducible to instruction and is not just a question of intellectual understanding. It involves intensity, resonance, and musical harmony. Its rationale is pragmatic and exists in the essential and positive relation to non-philosophy as a form of art that encompasses, in addition to critical thought, also clinical and creative dimensions located in experience and leading to new modes of existence as embodying new concepts, meanings, and values created in practice. It is an interdependence of thought and life and of mind and world that leads to Deleuze's philosophy encompassing both critical and clinical aspects. The critical dimension is compatible with Dewey's assigning to philosophy the function of criticism of criticisms. Yet his logic as a theory of practical, experiential inquiry necessarily includes affective thought. As for clinical, it is not derived from some discourse on pathology; instead, its model

is vitality, wholeness, and immanence aiming toward joy and devoted to the intensification of life.

An element of creativity is expressed in Deleuze's neologism *transcoding* that defies a habitual transmission of facts from a teacher to a student; instead, education becomes a transcoded passage between experiential milieus that leads to the construction of a new plane, as if of surplus value or the excess of potential meanings that were "dormant" in the unconscious. Deleuze uses musical metaphors of melodies in counterpoint serving as a motif for another. Thus, education informed by Deleuze's ingenious non-philosophy becomes possible only providing a teacher and a student serve as a motif for each other: they both, acting as a multiplicity, create a novel meaning that demonstrates *what the body can do* in accord with the logic of sense (Deleuze 1990) that defies direct (unmediated), logical or ideological alike, representations.

Conclusion

The role of a philosopher of education, if Deleuze's philosophy is used as a model, becomes the one of a clinician or physician of culture described as an inventor of new immanent modes of existence as making a difference in real life with regard to the ethico-political spectrum of experience. Such ethics is strongly opposed to morality. Morality presupposes rigid codes and norms embedded in the hierarchical structure of schooling or society at large, but ethics discards the existing norms in favor of new values created in experience, in life per se via the heterogeneous, multileveled, rhizomatic structures of multiple becomings. Indeed, Deleuze and Guattari designate the people of politics who can create real changes as a *people to come*. Because subjectivity has to be produced, these people may find themselves to be the uncanny products of untimely experimentations. They belong to "an oppressed, bastard, lower, anarchical, nomadic, irremediably minor race [and] have resistance in common – their resistance to death, to servitude, to the intolerable, to shame, and to

the present” (Deleuze and Guattari 1994, pp. 109–110). Resistance to the present means becoming aware of the future. This aspect of Deleuze’s practical and immanent philosophy is extremely important for educational futures. Education as inspired by Deleuze’s philosophy can transcend the physical present allowing to envisage multiple opportunities in the open future as a field of multiple becomings. We don’t have to generalize the politics of Deleuze’s philosophy, but rather posit a question, as Hardt (1993) does in his study: “What can Deleuze’s thought afford us? What can we make of Deleuze? In other words, what are the useful tools we find in his philosophy for furthering our own political endeavors?” (Hardt 1993, p. 119) or, for that matter, advancing and broadening the field of educational theory and philosophy.

Deligny, Fernand (1913–1996)

Pieter Verstraete
KU Leuven, Leuven, Belgium

Introduction

Since the past couple of years, the life and works of the French educator Fernand Deligny (1913–1996) increasingly have attracted the attention of artists, professionals, and academic scholars coming from divergent backgrounds. This current interest in Deligny’s work partly seems to be triggered by the 2007 publication of Deligny’s collected works and recently has led, among other things, to the publication of the first volume of texts translated from French into English, namely, *The arachnean and other texts*. Current interest in Deligny’s work, however, also needs to be framed within contemporary discussions about what it means to be human. Amplified by the societal challenges posed to both European as well as non-European countries in the past few years – one, for example, can think about the ongoing refugee crisis and the rise of ecological concerns – the question, for example, of how we can live together seems to address itself anew. As it becomes more and more unclear on the basis of what we can define what being human is about, how one should shape education in order to bring it about, and how we can continue to live together in our rapid changing societies; the radical ideals about language, subjectivity and education to be found in the work of Deligny will undoubtedly end up in thought-provoking debates and refreshing experiments.

Deliberative Democracy

The Art of Evading Language

Who was Fernand Deligny? This time, to pose the question is not to answer it. Drifting around on

that huge ocean of twentieth-century intellectual thought, Deligny's work cannot be fixed or turned into a system. It excels in its resistance toward all kinds of classification. Drifting around on the words, sentences, paragraphs, and images he produced throughout his life; the raft that consists of his actions, ideas, and dreams both departed from and floated upon the different (educational) theories and practices that alternated one another. There are of course things that can be said like the fact that Deligny was born in the city of Bergues in the North of France, that he started but did not finish his psychological studies at the university of Lille, that he lost his father during the First World War, and that he died at the age of 83 in the Cevennes, the region where he arrived in the night of the 13th on the 14th of July 1967. If this information can be said to provide the framework of his life, Deligny would time and again paint the canvas of his life anew, never to end up in a fixed state of mind, to produce a system or become institutionalized. Together with his aversion to institutions and becoming domesticated by some kind of symbol, Deligny's continuous attempts to live together with people who were dismissed as incurable, unlivable, and insupportable run as a red thread throughout his life. In the existing overviews of his life and work in general, four phases are distinguished. Not satisfied with his studies in psychology at the University of Lille, Deligny, first of all, started to work in the nearby psychiatric hospital of Armentières in the beginnings of the 1930s. Secondly, one refers to his work as an educator in some of the special schools for 'feble-minded' children in Paris around 1936. In the third phase, Deligny devotes himself to the development of a huge network for young delinquents called *La Grande Cordée*. And finally, one refers to Deligny's experiences with autistic individuals from 1967 onward. Two anecdotes taken from the first two phases might help to set the stage for which Deligny wrote innumerable scripts – some of which have not yet been explored as they are archived in some 38 boxes in the Institut Mémoires de l'édition Contemporaine (IMEC, Abbaye d'Ardenne, Saint-Germain-la-Blanche-Herbe, France).

The first example is taken from Deligny's passage at the psychiatric institute of Armentières. Besides the adult psychiatric patients, the walls of that institute also contained some children who were said to be "idiots" or "imbeciles." As at that time no special educational initiatives were deployed for these children, Deligny started a kind of sheltered workshop in the basement for these children. In order to run the workshop, Deligny needed some additional personnel. Instead of looking out for trained and certified educators or psychologists, however, Deligny deliberately only wanted to recruit his personnel from the large number of unemployed laborers that populated the North of France at that time. Not being plunged in and convinced by the contemporary pedagogical and psychological theories about human development and learning already at that time seemed to have been for Deligny a *conditio sine qua non* for the creation of opportunities where the self and the other could meet in a non-domesticating way. Not trying to frame the gestures and appearances of the other in some kind of preestablished order or structure also seems to have been central to his work as a special educator in the special school and classes in Paris toward the end of the 1930s. What does it mean to educate, Deligny asks himself in the preface to the 1976 reedition of a 1949 collection of stories entitled *Les enfants ont des oreilles*. When answering this question by saying that it is all about telling stories, Deligny refers to a particular experience he had with one of his pupils in the special class he was responsible for. All of a sudden, Deligny states, the boy found himself to his own surprise in front of the blackboard on which he had drawn something that appeared to be a rectangle. The boy probably had done so because he once had seen someone drawing a similar shape. Deligny, however, instead of asking the boy what precisely he had been drawing, what he was doing there in front of the blackboard, started to tell his class a story: "Once there was a table that had lost its legs. . . ." Together with the previous anecdote, this story about the boy in front of the blackboard demonstrates Deligny's continuous preoccupation not to end up in systems that consequently would form the basis in

order to represent the other. On the contrary, representation in general and language in particular seemed to stand for everything that Deligny tried to avoid. According to Deligny, our language did not differ much from the iron grids that were to be encountered when one opened the window of, for example, the psychiatric institute of Armentières. It was our words themselves who imprisoned the other and denied him or her the necessary time and space to develop a lifestyle of its own. Education, for Deligny, therefore should not be focused on the other – be it based on emotions of love or hatred. Education, first of all, should be directed to oneself and should consist in looking out for ways to evade one's own norms and values, deep-seated presuppositions, and jammed way of speaking. In a letter written to the communist Louis Althusser in 1976, he formulated this very clearly: "In our practice, what is the object? This or that child, 'psychotic' subject? For sure it is not. The real object one should transform, is ourselves, us there, close to those 'subjects', who, when we speak clearly, are hardly there and it is therefore, that THEY are, there."

Deligny refers to his initiatives as *tentatives* or attempts. In order to make clear what he considered to be a tentative, he at one point refers to the pearl divers. Intrigued as he was by some of the anthropological research conducted by, for example, Victor Turner and Daniel Fabre, Deligny came across this peaceful population whose main activity consisted in diving for pearls. In Deligny's account of the pearl divers' history, the fishermen in the beginning were confronted with a major problem. Time and again, when they wanted to locate the pearls on the bottom of the ocean, the men were confronted by their own image and thus not able to look through the ocean's surface. What they saw was the reflection of themselves. This, according to Deligny, is also what happens when we are confronted with another person. We are not capable of perceiving or making sense of the otherness of the other as this otherness is always hidden behind the reflections of ourselves. In order to counter the problem they were confronted with, the pearl divers needed to invent something that would enable them to look through their own reflection and thus beyond

the surface of the ocean. The simple technique they invented consisted of an old metal cookie box whose metal bottom was replaced by a piece of glass. It was this simple instrument that enabled the pearl divers to evade their own reflection and find the precious pearls on the bottom of the ocean.

Deligny's aversion toward language, however, did not end up in a kind of radical silence. Deligny continued to use words, to write and to speak. What he looked for were cracks and abysses where it would become clear that "water" – to mention just one example – was not only made for drinking. Applied to the question mentioned in the introduction, Deligny attempted to create spaces where subjects could again become individuals and show their humanity in ways that could neither be predicted nor restrained. The transformation Deligny was looking for was a transformation from a way of speaking that started from ONE to a way of speaking that originated from WE. The French word "on" (as in "on parle" or "one speaks") represented for Deligny everything that he wanted to stay away from as far as possible. The "on" referred to the innumerable ideologies that tried to mold the lives of individuals into particular shapes and to frame these by particular names.

The importance of this conspicuous attitude toward language again became clear to Deligny when he was confronted with the mother of a boy who was diagnosed by contemporary psychiatry as severely autistic and therefore intolerable, unbearable, and incurable. The boy's mother did not know what to do anymore as time and again psychiatric institutions and other organizations had refused to offer help. After being introduced to the mother and her son, Deligny decided to go to the Cevennes where he at first stayed in a house owned by Guattari. Confronted with the many negative reactions of students and intellectuals that frequented the same house – some of them simply could not handle the presence of the individuals Deligny decided to live with – Deligny moved to a neighboring commune where he continued his attempt to live close to those individuals contemporary psychiatry had abandoned. Besides the fact that Deligny had contacts with

Guattari – due to his stay in the psychiatric institution of *La Borde* – the Cevennes also attracted Deligny for some other reasons. Apparently the Cevennes played an important role in the French resistance during World War II. On top of that the Southern region was well-known for its bygone silk industry that matched perfectly well with the idea of wandering lines Deligny developed while living in the presence of people like Janmari, the teenage boy with whom Deligny arrived in the Cevennes in the year 1967.

People like Janmari constituted and still constitute a real problem for phonocentric societies structured around the primacy of the spoken language. In a 2007 video autism activist Amanda Baggs has offered the spectator a translation of her criticism toward this phonocentrism: “I find it very interesting by the way that failure to learn your language is seen as a deficit but failure to learn my language is seen as so natural that people like me are officially described as mysterious and puzzling rather than anyone admitting that it is themselves who are confused . . . We (autistic persons, PV) are even viewed as non-communicative if we don’t speak the standard language but other people are not considered non-communicative if they are so oblivious to our language as to believe they don’t exist.” Baggs’ plea for accepting the manifold forms language can take on – rather than to reduce these to one or two accepted ones – can be found back in Deligny’s attempt to create a communal space where the people with whom he lived could demonstrate their humanity on their own terms. Instead of normalizing the behavior and the communication between the “autists” and Deligny and his collaborators, a silence was looked for that would enable both to hear new sounds. It’s important to note, however, that in order to speak of an attempt, all intentionality should be out of the question. Attempts cannot and could never for Deligny be considered a kind of project that already knew where it would land. Attempts rather emerge from mere activities, actions, and gestures that for no reason in particular are repeated and after a while seem to contain some

meaning that could not have been foreseen. That for instance was the case with the drawings Deligny and his collaborators started to make from the end of the 1960s onward. While living in small communities in the mountainous area of the Cevennes, life consisted mainly of some daily activities (“coutumier” or “customary” in English) and daily walks. At some point one of the collaborators started to keep track of the wanderings of the boys and also those of the collaborators who lived together with them. After some days, weeks, or years of drawing, the practice consisted of drawings made on regular paper and drawings made on transparent wax paper, the former presenting the wanderings of the collaborators and the latter those of the boys. While the drawings nowadays increasingly seem to attract a lot of interest from art galleries, for Deligny they consisted of a technique that tried to avoid his own reflection, the domesticating nature of the language, and the symbols that we use when speaking about and with the other. After being put on top of one another, the regular and the transparent wax paper seemed to draw the attention of the collaborators to something they were not aware of, points of contact that both the collaborators and the boys/girls frequented. In between the gaze of the collaborators and the gestures/movements of the boys/girls, a space seemed to become visible where the other could show him-/herself in a way that was not predefined. For Deligny, as stated in his *Le groupe et la demande*: “il serait peut-être temps de repenser l’éducation en fonction de notre monde à plusieurs profondeurs.” The practice of drawing is only one of the attempts Deligny created throughout his life. Other examples of his eagerness to find cracks in the language we use and be able to reach new and unheard territories of humanity consisted in making use of the camera, for instance, something he reflected upon in one of his publications entitled *Le caméra, outil pédagogique*.

Up till today people are working and living in the Cevennes in the presence of one another/the other along the lines of what Deligny had called tentatives. Among others the French Jacques Lin

who published numerous publications on his experiences like *Le droit au silence* or *La vie de radeau*. As a trembling line of flight, Deligny's thoughts, actions, words, and gestures seem to inspire aesthetical as well as intellectual searches for new grounds where humanity can reinvent itself. Among other things one, for example, can refer to the work of the Belgian choreographer Alain Platel who already several times based one of his performances on the intangible heritage of Fernand Deligny. But Deligny also seems to have attracted the attention of philosophers like Giorgio Agamben in order to rethink the ways we can think about community. In a world that is hesitantly thinking about leaving the primacy of the individual in such a way that it will be able to avoid the pitfalls of nationalism and communism, the work of Deligny might become a simple empty, metal cookie box.

Dennett, Daniel (1942–)

Paulo R. Margutti Pinto
Universidade Federal de Minas Gerais,
Belo Horizonte, Brazil

Introduction

Daniell C. Dennett, American philosopher, is Distinguished Arts and Sciences Professor, Professor of Philosophy, and Director of the Center for Cognitive Studies at Tufts University (USA). His main concern is the philosophy of mind. He intends to give a mechanical explanation of the functioning of consciousness, harmonizing ideas from Wittgenstein, Ryle, Quine, and current results from experimental psychology. For this reason, he may be described as a thinker who advocates a certain type of Behaviorism by means of: (i) a skeptical attitude towards traditional philosophical discourse; (ii) a

thoroughgoing nominalism which rejects essences and ultimate truths; (iii) an optimistic scientism which includes the belief that the best explanation of the functioning of consciousness will be provided by an account of human beings qua biological organisms under evolutionary constraints. Dennett's approach is not only naturalistic, but also functionalist, in the sense that human organisms are biological machines whose behavior is controlled by their brains. Such a functionalism is connected with a prevailing interest in relations rather than in properties. This means that the "properties" of objects tend to be treated as relations and that objects are viewed not in themselves, but holistically, that is, in their connections with other objects. In many ways, Dennett's thinking is close to Rorty's, Nietzsche's, and Derrida's thinking. Dennett's style is very much fascinating. He is strikingly able to offer new ideas in a way which is accessible not only to professional philosophers, but also to the great public in general. This is usually done through his method of telling very imaginative elucidative stories, which he calls "intuition pumps," in order to make his ideas clear.

Dennett was born in 1942 in Boston. In 1963 he got his B.A. in philosophy from the University of Harvard. He got his Ph.D. in 1965, having worked under the supervision of Gilbert Ryle (University of Oxford – UK). From 1965 to 1971, he taught at U.C. Irvine. Since then he is teaching at Tufts University.

His main books are: *Content and Consciousness* (1969), *Brainstorms: Philosophical Essays on Mind and Psychology* (1978), *The Mind's I: Fantasies and Reflections on Self and Soul* (co-edited with D. Hofstadter, 1981), *Elbow Room: The Varieties of Free Will Worth Wanting* (1984), *The Intentional Stance* (1987), *Consciousness Explained* (1991), *Darwin's Dangerous Idea* (1995), *Kinds of Minds: Towards an Understanding of Consciousness* (1996), and *Brainchildren: Essays on Designing Minds* (1998).

Dennett's philosophy is full of theoretical innovations, of which Bo Dahlbom, in his Editor's Introduction to the book *Dennett and his Critics – Demystifying Mind* (1995), makes the

following list: the taxonomy of stances, the intentional systems theory, the consciousness of time, elbow room, hoping for hieroglyphics, free-floating rationales, abstracta and illata, centers of narrative gravity, virtual machines, real patterns, multiple drafts, heterophenomenology, the Baldwin effect, etc. For reasons of space, only some of these aspects will be treated here. In order to make a more comprehensive although brief exposition of Dennett's Philosophy, we shall develop in a more detailed way the main ideas in his method of heterophenomenology, his characterization of the "intentional stance," his Multiple Drafts model to explain consciousness, and his Darwinian perspective in philosophy.

Heterophenomenology

In Dennett's sense, "phenomenology" involves the description of anything that belongs to our conscious experience. The usual perspective adopted by traditional phenomenologists is Descartes' first-person perspective, in which I describe my internal experience in a monologue which I let other people overhear, counting on everybody to agree. This is based on what Dennett calls "the first-person-plural presumption": we (another person and I) may speak comfortably together about the things we both find in our streams of consciousness. But the first-person perspective is misleading and generates errors. In fact, we know that most reports made under such conditions are subject to controversy. We may be mistaken either about the extent to which we persons are all basically alike or about the reliability of introspection (instead of merely observing internal phenomena, we might be theorizing about them). Dennett appeals to an interesting "visit to the phenomenological garden," in order to show that we do have some privileged access to our conscious experience, but that we also do tend to think that we are much immune to error in this field than we really are. For this reason, he suggests that we should use the behaviorists' third-person perspective, according to which only facts gathered "from the outside" will count as data. Now mental events do not

seem to be among the data of science. But this does not mean we cannot study them in a scientific way. The challenge is to construct a theory of mental events, using only the data allowed by scientific method.

For accomplishing this task, Dennett offers the method he calls “heterophenomenology.” The method is neutral for investigating and describing the phenomena belonging to our conscious experience. It involves a cluster of experiments and observations in order to extract and purify texts from speaking subjects. Such texts are further used to generate a theoretical hypothesis, the subject’s heterophenomenological world, which is populated with all the images, sensations, events, and feelings that the subject apparently believes sincerely to exist in his or her stream of consciousness. This world is a neutral portrayal, in the subject’s own terms, of what it is like to be that subject. The data collected in this way correspond to “intentional objects” which must be seen from the “intentional stance.”

The Intentional Stance

Inspired by Ryle’s methods, Dennett attempts to dissolve the traditional approach to “intentionality.” This concept involves the idea that consciousness is always consciousness of something. Thus, the main feature of our mental states is the fact that they have a special type of “content.” In this sense, whenever we think, we think about such a “content,” which may be expressed by our beliefs and desires. And we govern the choice of our actions by considering such beliefs and desires. This is what makes our thinking rational. For this reason, intentionality is conceived as an essential property of the consciousness in human beings.

In a Rylean spirit, Dennett suggests that intentionality is not such a thing, but only a way to look at human beings. Whenever we look at them this way, we are taking what he calls the “intentional stance.” The latter may be defined as the strategy of interpreting the behavior of an entity as if it were a rational agent whose “choice” of a “line of

action” is determined by the “consideration” of its “beliefs” and “desires.” The “entity” in question may be either a person, or an animal, or a machine, etc. So, if we say that a certain moving robot chose to alter the course of its trajectory in order to avoid being shocked against an obstacle and being damaged, we are taking the intentional stance concerning the robot.

According to Dennett, there are three different ways by which we can look at an entity in order to understand its behavior. First, there is the physical stance, which consists in considering the behavior of the entity on the basis of the principles of physics. In this case, the entity is treated as an object that reacts in accordance with its physical properties (for example, when we predict that a stone released from someone’s hand will fall to the ground). Second, there is the design stance, which consists in considering the behavior of the entity on the basis of its general design. In this case, the entity is treated as an object that reacts in accordance with the way it was designed to react. We do not need to be acquainted with the physical laws involved (for example, we know that a certain alarm clock of which the buttons have been pressed in a determinate way will make a noise after some hours, although we do not need to know the physical laws involved by the clock in order to perform this action). Third, there is the intentional stance, which consists in considering the behavior of the entity on the basis of its rational choices. In this case, the entity is treated as an intentional system that chooses a particular line of action in function of its goals (for example, we might consider the alarm clock as our servant that has been given the command to wake us up at a certain time; we would then rely on its ability to understand our command and recognize the precise time of awakening). We may predict the behavior of the alarm as if it were a rational agent. The intentional stance is a useful linguistic shortcut in such case and reveals all its usefulness when the entity involved is more complex than an alarm clock, say, a computer or a person. If this is true, then “intentionality” is not to be taken too much seriously. It should be treated as a useful fiction and not as a real property of consciousness.

The Multiple Drafts Model for Consciousness

According to Dennett, although materialism is now an opinion approaching unanimity, even the most sophisticated materialists often forget that discarding the Cartesian *res cogitans* involves rejecting the need for a functional center to the brain. Thus, some materialists discard Descartes' dualism while preserving the idea of a central Theater where everything is somehow put together and the stream of consciousness occurs. This approach, which is still based on the idea that the brain has a centered locus, may be called "Cartesian Theater model." This is a very useful metaphor and seems the natural way to explain, for example, the sequence in which events may be observed when macroscopic time intervals are involved. But when it comes to microscopic time intervals, the model faces so many difficulties that it should be abandoned.

As a matter of fact, suppose the study made by Kolers and Grünau on the phi phenomenon (1976). This phenomenon was first studied by Wertheimer (1912) and consisted of two small spots separated by a small visual angle which were briefly lit in rapid succession and which were perceived as a single spot moving back and forth. In an analogous experiment, Kolers and Grünau used two spots differing in color and unexpectedly observed that the first spot seemed to begin moving and then changed its color abruptly in the middle of its passage toward the second location. Suppose the first spot is red and the second is green. In this case, our consciousness would have the following order of experiences: first red, then red-turning-to-green, and finally green. Now this raises a problem: how is the brain able to fill in the spot red-turning-to-green before the green spot is seen? The illusory content, red-turning-to-green, can only be created after some identification of the green spot occurs in the brain. So, we must conclude that our consciousness of the whole event must be delayed until after the green spot is perceived. But Dennett argues that this explanation is still based on the Cartesian Theater.

In order to explain this, he appeals to a thought experiment. Suppose someone watches a woman walking with no glasses, but he or she remembers her as wearing glasses. The Cartesian Theater offers two competing explanations for this: (i) the Orwellian revision, according to which the subject actually saw the woman with no glasses, but an instant later his or her memory is revised and then he or she firmly believes that she wore glasses; (ii) Stalinesque revision, according to which the subject actually hallucinated that the woman was wearing glasses from the moment he or she saw her. The expressions "Orwellian" and "Stalinesque" were used under the inspiration, respectively, of George Orwell's novel 1984, in which the past was revised in conformity with political interests, and Joseph Stalin's dictatorship, in which the present was revised by means of show trials, involving false testimonies and bogus confessions. At this point, Dennett argues that these are not distinct possibilities no matter how finely we divide up time. When the intervals of time are sufficiently tiny, the distinction between memory revisions (Orwellian) and perceptual revisions (Stalinesque) fades away. We cannot decide what really happened on the basis of the subjects own testimony. Now if the Cartesian Theater model were true, this question would have an answer at any point. For the model requires that there must be a content that reaches consciousness first: either walking woman or walking woman with glasses. We must realize here that the experiment implies that there is no privileged "reaching consciousness." Thus, the question about which explanation, Orwellian or Stalinesque, is the correct one is mistaken and has no answer, since the onset of consciousness does not occur at a precise point located in time.

The alternative Dennett offers is the Multiple Drafts model, according to which all varieties of mental activity are accomplished in the brain by parallel, multitrack processes of interpretation and elaboration of sensorial data. All information that enters the nervous system is under continuous "editorial revision." Dennett illustrates this by recalling that our eyes movements consist of quick fixations, about five a second. This means

that they move much more than our heads. So, the images in our retinas should be trembling all the time, just like the images in some home movies taken by inexperienced people. But this is not what we see. The motions of our heads and of our eyes are edited before they reach consciousness. The editorial processes occur over large fractions of a second, in different orders, and during this time several additions, emendations, and overwritings can occur. We experience directly the results of our brains' editing out our sensory inputs, and not what happens at the edges of our sensory windows (retinas, tympanic membranes, skin surfaces, etc.). And a particular editorial process is made only once by a specialized portion of the brain. There is no need of further edition which would be made by a "master" editor (the Cartesian Theater). Besides, it is an open question whether any edited content will eventually appear as a constitutive element of our conscious experience. It would be a mistake to ask when such a content becomes conscious, because the functioning of the brain involves many sequences of edited contents which are simultaneously distributed around in different portions of the brain. All these sequences are subject to continual editing processes and they yield, over the course of time, something rather like a narrative stream: "at any point in time there are multiple 'drafts' of narrative fragments at various stages of editing in various places in the brain" (*Consciousness Explained*, p. 113). Some of the contents in these drafts will make no contribution at all, some will make only a brief contribution and fade out, some will persist to play a variety of roles in the further modulation of internal states and behavior, and some will even persist to the point of revealing their presence through verbal behavior. The Multiple Drafts model unveils the mistake of supposing that there is a "final" narrative or "published draft," which would correspond to the actual stream of consciousness within the subject. But how is it that we seem to be singular conscious agents to ourselves and to other people? Dennett argues that the idea of a "self" results from our fundamental tactic of self-protection, self-control, and self-definition, which

consists in telling stories about who we are. We do not consciously and deliberately figure out what narratives to tell and how to tell them. But we do not spin our stories: rather, they spin us. Our human consciousness is their product, not their source. These narratives appear as if they came from a single source, encouraging the audience to posit a unified agent as such a source. In doing this, the audience is positing a center of narrative gravity. Physicists take great advantage in positing a center of gravity for an object, a single point relative to which all gravitational forces may be calculated. In the same way, heterophenomenologists take great advantage in positing a center of narrative gravity for a narrative-spinning human body. In this way, human consciousness is explained in terms of the operations of a "virtual machine," a kind of evolved and evolving software that shapes the activities of the brain. According to Dennett's model, the role of an inner center is played by the brain's networks. For a mental content to become conscious, it has to win a battle against other mental contents. And that is all there is to consciousness.

The Theory of Evolution and Its Consequences

The Theory of Evolution through constant change and selection is another tool Dennett uses for explaining the emergence of complex phenomena, such as consciousness. As a matter of fact, he thinks we descend from self-replicating macromolecules of which the "impersonal, unreflective, robotic, mindless little scraps of molecular machinery are the ultimate basis of all the agency, and hence meaning, and hence consciousness, in the world" (*Kinds of Minds*, p. 22). In this perspective, each cell is as mindless as a virus, but whenever we put together a sufficient amount of cells, we obtain a conscious person, with a genuine mind.

The book *Darwin's Dangerous Idea* evaluates the consequences of the Theory of Evolution in biology, cognitive science, and linguistics, locating all the previous aspects of Dennett's

philosophy within a more general framework. According to Dennett, Darwin's theory implies that the various processes of natural selection, although basically irrational, are powerful enough to have made manifest the whole planning work in our world. Darwin's dangerous idea lies in the fact that all things resulting from evolution may be explained as by-products of an algorithmic process. There is a single unified design space in which all creative processes, biological and human, follow their tracks, using similar methods. In this perspective, biology and engineering are the same thing. Both study functional mechanisms, their design, their construction, and their operation. Once we adopt the perspective of engineering, we are able to explain and unite the central biological concept of "function" with the basic philosophical concept of "meaning." Human species differs from all other species in virtue of our confidence in the cultural transmission of information, therefore in cultural evolution. Dawkins' meme, the unit of cultural evolution, plays a powerful role in Dennett's analysis of the human sphere. Memes are units of cultural transmission, or of imitation, such as tunes, ideas, catch-phrases, clothes fashions, etc. Genes propagate themselves by leaping from body to body via sperms or eggs, and memes propagate themselves by leaping from brain to brain via imitation (Dawkins (1978), *The Selfish Gene*, p. 206). Dennett thinks that human brains are invaded by culture, under the form of memes. This has created human minds. It is the molding of our minds by memes which gives us the power to transcend our selfish genes. One of the memes, the process of generate-and-test, which is much more refined than the mere trial-and-error process, leads to more powerful kinds of minds, culminating in intentional generating-and-testing of theories by human beings. In this process, the role played by language is fundamental. The meanings of our words result from originally irrational processes, that is, the algorithmic processes which created the whole biosphere. In this perspective, Dennett thinks that even ethics may be redesigned in a

Darwinian sense, steering successfully between the traps of Utilitarianism and Kantianism.

Introduction

Jacques Derrida attacks the claim that writing is a progressive extenuation of presence. This notion

of presence is derived from a classical, metaphysical necessity, a logocentric ideal, and it is this idea of a stable presence in communication that Derrida deconstructs. Indeed, logocentrism and exclusively verbal communication are argued against in edusemiotics. Derrida refers to how writing is assumed to be a means of communication extending the possibilities of locutionary and gestural communication. The issues concerning the hierarchy of speech over writing play a major part in Derrida’s writing. This entry outlines the movement away from Saussure’s structuralism and toward difference and arbitrariness to unveil a greater uncertainty and undecidability in language and subject through the notion of trace as all signs bear the traces of other signs from which they are differentiated so that be meaningful. The idea of the trace points toward a kind of ambiguity and uncertainty in the origin of meaning as the production of difference. The text becomes a chain of signs. By tracing and exploring Derrida’s idea of difference and *différance* in a

Derrida and the Ethics of Reading, Table 1

Derrida intimates on deconstruction as a possible offspring of structuralism at the end of his famous lecture at Yale University, “Structure, Sign, and Play in the Discourse of the Human Sciences” (1966). What is it that play does to the sign that is evident in the semiotics of signification: the structural necessity of its repeatability, or reiteration, beyond a single, unitary point of expression. The broader and more radical conceptualization that encompasses every kind of expression, communication, and coding (phonic, graphic, artistic) leading to a poststructural ethic of reading “can be called *gram* or *différance*” (Derrida 1981, p. 26). A sign can signify only through the force of repetition, the consequences of *différance* rendering signs *relational* rather than being a priori identical entities, and bringing indication in line with expression to undo the Husserlian idea of a “pre-expressive intentionality” of pure consciousness and the reading of signs. The subject thus is decentered as brought out of the shell of self-centered Cartesian *Cogito*. The Other is effaced to the point where an inner monologue with one’s “Self” is not really an instance of transmissibility, but the self-deceptive verification of the desire for auto-affection or an attempt at the reduction of *différance*. In order to ascertain the existence of itself and read the empiricism of consciousness, a subject must refer

Derrida asserts that if the signifier is uncoupled from the signified and the word is released from its precise definition or a preexistent concept, the signifier would move freely while the signified becomes yet another signifier. Any attempt at mapping discourse to a preceding codified framework of interpretive intensions and extensions represents an act of power. The poststructuralist dissemination of meaning, its splitting open, undermines the fundamental hermeneutics of semiological assumptions. First, dispersal considers the linguistic determination of a sign value in relation to, and in difference from, other signs. However, when the production of meaning is traced in this way, the act of interpretation presents itself only through recourse to yet another series of signs, each again defined by its relation to, and difference from, existing and generated signs. This chain of attempts to make meaning of the writing of signs continues indefinitely through reading; thus, a teleological end or precise definition is never reached. Meaning is never fixed outside of its relation to the process of sign production within a written text or spoken discourse. It is always uncertain while remaining determined in the textual concatenation of signifiers and the deferral of meaning from the repetition and difference of signs.

Derrida and the Ethics of Reading, Table 1 (continued)

outside of itself to the world of signs using the resources of what does not begin within itself, therefore striving to refrain from obliterating itself just as it seems to have authenticated the uniqueness of its (own) existence. It is this *relational* aspect that brings an ethical grounding of reading the signs of the other in *différance* by referring to the constitutive function of the sign trace of the Other in reading the Other: the deferring difference between presence and repetition, self and nonself, reveals itself as uncertainty and ambiguity at the proliferative core of identity.

Returning to the text of the lecture, Derrida suggests that *différance* is, or can stand for, “the juncture – rather than the summation – of what has been most decisively inscribed in the thought of what is conveniently called our ‘epoch’” (Derrida 1973, p. 130). A poststructural age of the irreducible play of the sign marks the delimitation of onto-theology, the decline of the inherited metaphysics of presence (phono-logocentrism), and the possibility of an ethical opening of the subject toward the difference of the Other. But we must remember, however, the role of tradition in the formation of new thought. The following philosophical notions are given by Derrida as examples of difference that led to *différance*: “the difference of forces in Nietzsche, Saussure’s principle of semiological difference, differing as the possibility of [neuron] facilitation, impression and delayed effect in Freud, difference as the irreducibility of the trace of the other in Levinas, and the ontic-ontological difference in Heidegger” (Derrida 1973, p. 130). All of these individuals have no doubt figured greatly in the elaboration of the *working of deconstruction*, but more importantly the list displays the “discoveries” or “inventions” of varying fields from the history of philosophy to theology, linguistics, and psychoanalysis, that have changed or altered perceptions of the ethics according to Western metaphysics, the cognizing subject, and pedagogy in their refusal to be subdued or dominated by the dizzying substitutions of master signs within its self-enclosed system of truth and meaning. As such, *différance* is not only “irreducible to every ontological or theological – onto-theological – reappropriation, but it opens up the very space in which onto-theology – philosophy – produces its system and its history. It thus encompasses and irrevocably surpasses onto-theology and philosophy” (Derrida 1973, p. 135) and, importantly, elicits a new ethics of reading the signs of the other. The elocality of its structure also prevents an afore-planned linearity within the reading of the writing of signs, for example, the ordering of a “reason” of strategy or of finality of purpose, a tacticality toward teleology, “philosophical-logical discourse” (Derrida 1973, p. 135), and its symmetrical opposite, “logico-empirical speech” (1973, p. 135). The alternative to these more or less traditional discourses of epistemological fortitude and the basis of a theory of reading and the Other is the semiotics of the play of difference as *différance*.

Indeed, the pragmatological plane of philosophy, the

Second, deferral of meaning relates closely to dispersal. Following the chain of dispersed meaning through the production of signs composed of words and semantic units of sense and so on defers interpretive teleology in semiotic multiplicity. It is not until a representational endpoint of reading is reached that the possibilities of meaning in signification can be adduced. The deferral of meaning then is infinite because there is always a wait for prerequisite meanings. And so, meaning is both dispersed along endless chains of signifiers and deferred until the ends of these chains are reached and open up the possibility of interpretation. Meaning then is forever caught within the infinite play between signifiers.

Derrida’s arguments for dispersal and deferral make it impossible for a definitive meaning to be reached with certainty. The meaning of a signifier, the signified, is always referred to its prior usage in previous discourses, and this meaning is always deferred. It is therefore not feasible to speak of a transcendental signified or transcendental semantic meaning as meaning is not centered or fixed but, as Derrida (1974) reminds us, is caught up in a play of relations and difference between signifiers and signifieds. It is this denial of a fixed center that ultimately undermines meaning in a structural sense and gives rise to the term poststructuralism. Meaning is never present but comes from what the sign is *not*, from what is absent, and from relations to other signs. Present too exists in relation to the past and to the future: thus paradoxically stays present in its absence. The subject too is not present but is a consequence of language via this fluid and undecidable play that is the power of *différance*. *Différance* reflects Derrida’s arguments of dispersal and deferral as it encompasses both the meanings of *to differ* and *to defer* allowing for deconstruction to work.

Deconstruction provides a way of reading texts and discourses that allows for themes and assumptions which appear to be “at war” with each other to be realized and recognized; it “liberates the repressed contradictions *always already* present within the constitution of the texts on the subject referred to, using the selected terms of their expressions and expressivity to interrogate” (Trifonas 2000, p. 274). Derrida notes that within traditional philosophy, binary oppositions (e.g., culture and nature, man and woman, etc.) are situated within “a violent hierarchy. One of the terms dominates the other (axiologically, logically, etc.), occupies the commanding position. To deconstruct the opposition is above all, at a particular moment, to reverse the hierarchy” (Derrida 2004, p. 39). Derrida asserts that deconstruction “must, by means of a double gesture, a double science, a double writing, practice an *overturning* of the classical opposition and a general *displacement* of the system” (Derrida 1982, p. 329). This action of deconstruction within discourse identifies the operations in the text that form arguments, concepts, or premises, in turn illuminating how hierarchical oppositions as well as stable philosophical foundations can undermine themselves.

By carefully opening texts and discourses to release the

Derrida and the Ethics of Reading, Table 1 (continued)

reading of the signs of the Other and its constitution, is of keen interest to Derrida especially in relation to the problem of the ethics of reading stemming from deconstruction and the reconfiguration of writing. “What links writing to violence?” (Derrida 1974, p. 101): it is the radical materiality or exteriority of the sign (that as such partakes of the radical rationality of edusemiotics). In its expansion or reduction, writing is the stuff of violence itself, but so is the reading of signs. Language is customarily an oriented structuring, a principal manifestation of hierarchization that ranks, classifies, and separates according to a system of differences or polarities by the subjective placing of value to objectify entities according to binary coding. Writing is a deconstructive metaphor for violence performed in reading. This dyad is a hermeneutic expression of supplementarity for the attribution of cultural value that creates hierarchies perpetuating all forms of social inequality or reinforcing situations of power and domination. Writing is the means for a system of representation that makes the attempt at the community of speech and logocentric communication impossible for the reason of the ordering of “the space of its possibility, the violence of the arche-writing, [and] the violence of difference” (Derrida 1974, p. 110). The desire to escape violence and repression of meaning by examining the edusemiotic dimension of reading is to endeavor to think the unthinkable outside of the sign of writing. For what comes before language and representation, speech and phenomena are always already unreachable. It is a hermeneutical violence that permits the only ethical possibility of deconstruction as the recognition of *différance*.

As such, the “text” and “textuality” of writing is a chaining of signs, not simply sign functions standing in for a cultural center of mediated meaning but “everywhere, differences and traces of traces” (Derrida 1981, p. 26), within which the *gram* would come to be the most general sign and semiology would be therefore reconstituted as *grammatology* and a new ethics of reading.

It is as *différance* that the grammatological transformation of semiology takes place via deconstruction. But, there are some crucial sticking points: on the basis of the above function, *différance* is incompatible “with the static, synchronic, taxonomic, ahistorical motifs in the concept of structure” (Derrida 1981, p. 27), and yet, contrastingly, it is *not* “astructural” because the “systematic and regulated transformations” (p. 28) in the specificity of its general workings are able to develop “the most legitimate principled exigencies of ‘structuralism’” (p. 27). It cannot be said that some “present and in-different being” (Derrida 1981, p. 28) in any shape or form “precedes *différance* or spacing” (Derrida 1981, p. 28), for example, a subject “who would be the agent, author, and master of *différance*” (Derrida 1981, p. 28), or upon whom *différance* would impose itself. To Derrida, “Subjectivity – like objectivity – is an effect of *différance*, an effect inscribed within a system of *différance*” (Derrida

voice of the Other and freeing meanings from rigid and unquestioned boundaries of Western metaphysics, deconstruction also becomes, importantly, an ethical action. It requires a close and mindful understanding and also a respect for the subtleties of the text or discourse: To “deconstruct” philosophy, thus, would be to think – in the most faithful, interior way – the structured genealogy of philosophy’s concepts, but at the same time to determine – from a certain exterior that is unqualifiable or unnameable by philosophy – what this history has been able to dissimulate or forbid, making itself into a history by means of this somewhere motivated repression (Derrida 2004, p. 5).

Deconstruction makes possible the opening of an inclusive space “without barriers or boundaries, though not without obligation and the danger of failure” (Trifonas 2000, p. 279). It does not take down the existing structure of a text or discourse but rather locates within it a more neutral site from which to question and reverse oppositions:

... it is [this] non-ground between presence and absence [that] deconstruction breaks-into, slowly making it possible to imaginatively empathize or ‘fill-up’ the openness of the abyss of this excluded space, the space of the writing/teaching of the Other, to re-approach the responsibility of the horizon of inter-subjective violence, and the teleologicality of the cultural politics of the sign (Trifonas 2000, p. 276).

Deconstruction refuses to anchor epistemology in any authoritative foundation, and it does not propose a “better” theory of truth but instead allows for the illumination of those impassables that surface in our attempts to reveal truth. As a way of reading and writing and of analysis and criticism, deconstruction focuses its critique upon the text. It does so not by attempting to escape the metaphysics of language but by highlighting and subverting its very character (Peters and Trifonas 2005). Deconstruction fills the void where “‘a change of style’ is needed, one that will ‘speak several languages and produce several texts at once’” (Peters and Trifonas 2005, p. 6). Thus, it is not possible to reduce deconstruction to a method that is distinct from the political and institutional; it always interrogates the structures and discourses upon which it stands. Because of this, deconstruction holds destabilization as a central theme. Deconstruction “signifies not the demolition of what is constructing itself, but rather what remains to be thought beyond the constructivist or deconstructionist scheme” (Derrida 1988, p. 147). Deconstruction, though, does not lead to indeterminacy but rather undecidability as “always a *determinate* oscillation between possibilities . . . These possibilities are themselves highly *determined* in strictly *defined* situations” (Derrida 1988, p. 148). For Derrida, undecidability allows for the examination of relations, differences of force made possible by play, nonidentity, and *différance*. Indecision exists “between determined (semantic, ethical, political) poles, which are upon occasion terribly necessary and always irreplaceably

(continued)

Derrida and the Ethics of Reading, Table 1 (continued)

<p>1981, p. 28). The grammatological reconstitution of Saussure's semiology enables the rethinking of reading and draws attention to the historicity of the deferred traces of writing the difference of the Other. Deconstruction contends for an ethics of reading that is beyond the cognitive limits of the teleological trajectory of the subject of metaphysics. "How do we conceive of the outside of a text?" (Derrida 1973, p. 158). We can reply to this essentially unanswerable question with another: how do we conceive of the inside of a text? And to some extent, the thinking of <i>différance</i> broaches an impossible answer to the radical opening of the ethics of both of these aporias of reading and writing all along.</p>	<p>singular" (Derrida 1988, p. 148); for this reason, deconstruction must not result in extreme relativism or any indeterminacy. It displays a subtle radical, even if paradoxical, rationality – such as the one displayed by edusemiotics (Semetsky 2013; Stables and Semetsky 2015) as the educational theory inseparable from the ethical practice of reading signs that suspend the presupposed centrality of the a priori conscious and certain of itself subject and defy logocentrism.</p>
--	--

dialogue with his important texts, the entry engages the parameters of how an overall sense of ambiguity, arbitrariness, a definite uncertainty, or undecidability is intrinsic, even necessary, for language to function as an ethics of reading and textuality. This uncertainty strikes at the heart of logocentric Western metaphysics and enables Derrida to ground deconstruction in relation to the exclusion of writing in the history of philosophy and a new ethics of reading so important for education.

Toronto, OISE/UT, Toronto, ON, Canada

Philosophy consists of offering reassurance to children. That is, if one prefers, of taking them out of childhood, of forgetting about the child, or, inversely, but by the same token, of speaking first and foremost for that little boy within us, of teaching him to speak—to dialogue—by displacing his fear or his desire. Jacques Derrida, *Dissemination* (1981)

Jacques Derrida is indeed a most profound thinker of matters educational, addressing in highly provocative and original ways through, more or less, “unconventional” readings of the history of Western metaphysics, some of the most basic philosophical questions of teaching and of learning. Michel Foucault and Edward Said have suggested – albeit in derisive ways – that deconstruction is perhaps nothing else but the elaborate

expression of a new didactics, a poststructural pedagogy of the text. (See Said 1978; Foucault 1965. In an appendix to the 1972 edition (the original was published in the form of a Thèse d'Etat in 1961), Foucault responds to what he perceived to be an "attack" on his work by Derrida in the "lecture" "Cogito and the History of Madness," trans. Alan Bass, in *Writing and Difference*, 31–63 by describing deconstruction as nothing more than a conservative and well-entrenched "pedagogy of the text.") And yet, on the one hand, to say Derrida presents the means to a "method" of teaching, and this only would be wrong, for there are no directives to educational practice prescribed, no rules imposed upon the right to a "freedom of thinking" or responsiveness, and no apriority of absolute truths to be found as could suffice to constitute the operational basis of an ideal model or mode of instruction. But, on the other hand, the "philosophemes of deconstruction" carry on the "contradictory and conflictual" *polemos* of a theoretical backdrop that looks forward to the real necessity of informed action transcribed across the poststructural, post-phenomenological passage from "thetic" to "athetic" rationality.

The "movement" of deconstruction is away from an obstinate stance of single-minded opposition ready to tear down the existing "system" and toward an economy of reflective matriculation within the structurality of the institution to a working out of the essential trials of its undecidability at the expense of the metaphysical grounding of its architectonics. Due to the awareness of the stretched parameters of the dilemma of this "double-sided" stratagem, the tensions of its aporias open up the ethics of deconstruction with respect to the politics of education, and there is no need to enact the finality of the last word on the subject, especially in the form of a statement, "of positional or oppositional logic, [overdetermined in] the idea of position, of *Setzung* or *Stellung*" (Derrida 1983). This would be both problematic and irresponsible given the non-adequation of the "critical demonstrativity" of Derrida's texts with the desire for settling upon an undisputable and self-revealing truth. The metaphysico-theoretical fidelity of such a standard closing of

argumentation seeking to culminate in a full stop of studied silence would most surely contravene the unpredictable interspaces of the risk of writing that opens signification up to an insertion of the alterity of the Other and invites the creation of the difference of meaning as the disseminative interruption of a stable conditionality of the sign. There is therefore a canceling out, in advance, of the possibility of any coming to resistance an examination of the ethico-political exigencies of deconstruction could run against in relation to a "thinking of the end" as the telos of philosophy by being contrapuntal to the curricularization of pedagogy oriented from the "historico-topologico-sociocultural" regulation of its implementational styles. Still, we must proffer reasons and bestow "sound reasons" in good faith for the sake of the institutional reason of deconstruction as a just way of thinking and knowing. It is necessary to justify, in principle and by practice, the tendency of a hesitation to simply conclude that Derrida is a "philosopher of education," thus accepting responsibility for the lack of *clôture* to those unread or underread texts of Derrida's the "educational texts," as I have described them, writings that will always already be open before us.

And yet while attempting to summarize the importance of Derrida to educational thought, I would like to follow the path of a certain non-repetition of form and formality which does not mean it is necessary to abdicate rigor or the demands of a scholarly obligation, "to substitute for what exist[s] some type of non-thesis, non-legitimacy or incompetence" (Ibid., p. 42) but rather requires the assumption that an even greater accountability be demanded of the critical invention of the transformative gesture to explain itself both now and later. The beginnings of a path breaking cannot take place without a careful knowledge and an immense respect or keen observance for the most ever subtle nuances of "academic tradition." And in this way of unpromising justness surpassing the minimal responsibility of the protocol of "good conscience," this trail blazing is what deconstruction does above all else or makes possible regarding the most fundamental of educational themes, "what it means to know." Derrida has articulated

as much through a prolific body of texts sometimes taken to be anathema to the history of knowledge and knowing after the legacy of the ancient Greeks. Deconstruction traverses the ethics and the politics of the logic of the Same to introduce from beyond the horizon of its impossibility the transcendence of a teaching/writing of the Other. It upsets the surety of the “phenomeno-semiological” foundation of the institutional history of Western epistemology at the level of its theorizing about the value of the sign, reproducibility, and representation or what is the heart of the educational future of all philosophy and science as indicative of the empirical foundation of the certainty of truth:

- *For nothing can be taught or learned other than what is believed to be known and understood.*

From the above premise follows the “theoretical matrix” of deconstruction. Derrida has developed its principles most conspicuously in *Of Grammatology*. The point is that it is indeed feasible to intervene at the base of the institutional monolith amidst the play of the forces of the particular implications and effects, leading to and resulting from the exclusion of writing by metaphysics. Through the imperious dismissal of exteriority, the ethnocentric terms of the limits of signification and meaning creation are posited in the immediate (tonal) substantiality of the voice or speech for the reduction of difference within the ideal determination of the self-presence of the logos. In this sense, it is the nonethical beginnings of the “ethnicity” of the teachings of metaphysics and the “living reason” of the spoken word that warrant, because it underwrites the closing off of the trace of otherness. The unique importance of the “grammatological” focus when juxtaposed against the anteriority of its semiological influences is remarkably suitable here. Its consequences for education resonate when the confrontation of writing and voice within the Derridean conception of a “poststructural” version of “understanding” or “meaning making” surpasses the nomothetics of speech; a reinterpretation of philosophy through the cultural politics of the sign is necessary.

An analytical “breaking down” of the constituent features of the reason of its prejudice concerning consciousness and language delegitimizes the onto-theological groundedness of the voice feeding a pedagogy of *mimesis*, an imitativeness of the example or a clarifying of explainability required for the sake of perpetuating the illusion of truth from the demands of an altogether “natural” or “good usage.” The problem of negotiating the arbitrary objectification of the semantic values of the cognitive and affective results comprises the interpretative bandwidth of the episteme framework that constructs the institutionalization of theory as praxis. I would contend that this realization brings to the fore the importance of the question of ethics for deconstruction relative to the theme of education, teaching, and learning. And this is where we will already have begun to examine and articulate the pedagogical ramifications of deconstruction so prominent in the radical specificity of the scope of Derrida’s engagement with the genealogy of philosophical concepts. By enabling an investigation of the semiologicality of the metaphysical model of cognition crucial to the scene of a “classical pedagogy” that posits the flawless transmission of signs between the relational formulizability of a “sender-receiver” dyad and, hence, the possibility of the inter-exchanging of well-received meanings, deconstruction reveals how the privileging of speech over writing is the ethnocentric outcome of comprehending the representationality of language formations or their potential for expressivity solely as an “economy of signification” involving the immediate and auto-affective substantiality of the spirit of the voice. This skepticism of the teleology of the predication of the desire to communicate can lead to a pushing beyond the “vulgar” notion of a teaching and learning directed, without doubt, as the transference and implantation of the truth of knowledge from “above” and “outside” the psychico-experiential realm of an intersubjective violence. For example, it permits a renouncing of the tabula rasa theory of the inscriptibility of a malleable consciousness of unblemished wax to be shaped or given image by the artful engraving of a master teacher operating at the critical points

of a “weakness to know” where the clean slate of subjective being is at the mercy of the probing intentionality of the deep etching of signs.

Derrida characterizes the conventional or classical act of teaching and learning to be the pragmatic reproduction of the “metaphysics of presence” as cultivated from the premises of the interchangeable chain linking of its orienting function at the fabulaic center of the syntagm of the Western mythos of “pure origins,” uncorrupted beginnings. As the *arche-thememe* of logocentrism defining the effluence of the voice, it stands in symbolic difference and non-difference to itself, a *mise en abîme* of an archetypal thinking of the plenitude of the sign that guides the conceptual immanence of an archive of cultural knowledge, be it scientific, aesthetic, philosophical, religious, and so on, to render it replicable without a hint of doubt. For example, Derrida’s reading of Jean-Jacques Rousseau regarding the origins of language “before the letter” concentrates on the foundational and corollary arguments detailing the elements of a pedagogical method relying on the phonocentrism of an image of the natural piety of humanity to bring out the extent of the incoherence of the utopianism of an idyllic vision of a “community of speech.”

Deconstruction exposes the blindness of the figural identification of innocence prior to the exteriority of the voice as the mark of writing – e.g., the worldliness of delimited contextuality and the predictable consequence of sign-meaning correlations – through which a resistance to the difference of supplementation is operationalized by the romantic appeal of the rhetoric used to secure the nostalgic call for the elimination of the violence of culture from the organismic whole of a society capable of pure spirited, unaffected relations of genuinely filial obligation. Derrida “turns back” upon Rousseau the question of the social construction of concepts such as “immediacy,” “propriety,” “nature,” and so on. The point is to show the ways in which the applicability of deconstruction for the general problem of education extends from its ability to liberate the repressed contradictions always already present within the constitution of the texts on the subject referred to, using the selected

terms of their expressions and expressivity to interrogate the deeper facets lamenting the catastrophic passing of naive simplicity to learned experience. The nonethical postscript of the irreversible transformation of the child is represented by the inculcated ability for the apprehension of the metaphysics of the sign and the debility of representation, (de)contextualization, removedness, and supplementarity, honing the displacement of the truth of the Being of being in the moment of the reversal of self-identity through teaching and learning. Deconstruction, however, if we are to believe Derrida, does not, cannot, nor does it wish to exact the death of logocentrism and to eliminate it, despite troubling the epistemic validity of a phonological prototype of signification that linearizes the relation of signans and signatum. It inhibits the reduction of the play of difference in an effort to counteract and counterbalance for the mitigation or repression of the presence of the Other within the expression of the Same.

Behind the improbable terms of the educational connection of semiology as an “old science of signs” and deconstruction as a “new way of reading” lies the presupposition that “there has never been anything but writing” (Derrida 1974), a circumspection bringing to fruition the contextual overdrift or grafting on of the grammatological to the pragmatico-theoretical field of (philosophical) anthropology. To keep within the “age” of Rousseau and a certain “autobiographical temporality” of a self-present *écriture* is not difficult for Derrida, when considering the structural ethnology of Claude Lévi-Strauss. For it is through the teaching of one, the former, who excludes the supplementarity of writing yet, nevertheless, wants to add to a supposedly ideal state of human nature and provides an educational manual to do so, that another, the latter, transforms the discipline of anthropology as a science of difference wanting “to decipher, dreams of deciphering a truth or an origin that transcends play and the order of the sign, and for it the necessity of interpretation is lived as a kind of exile” (Derrida 1978). The ethical aspects of the deconstruction of the ethnocentrism of the description of the Nambikwara in “The Writing

Lesson” of *Tristes Tropiques* illustrate the ramifications of the intersubjective violence Lévi-Strauss exacts upon this group of people in light of the cultural politics of a structuralist agenda dismissive of script, but still using the distinction of the graphie to hierarchize, categorize, and exoticize the Other by Western criteria of belief, knowledge, or education.

The logocentrism of semiology encompasses a theory of language and representation that reduces the elements of teaching and learning to the preserving of (self-)presence; in fact, it precludes, on a more significantly ethical plane, the possibility of the recognition of difference outside of a closed system of an authenticating set of limits, the opposite extremes for inclusion and exclusion. The cultural politics of the sign works through these opposite extremes by reinforcing the objectification of value toward the “practical” purpose of the inclusion and exclusion of entities. To say, and Lévi-Strauss does, that the Nambikwara lack the mark of “writing” and are therefore closer to nature than to culture is not only to be wrong but also unethical, because the judgment recuperates the stereotypical image of the “primitive mind” as diachronically untaught and technologically undernourished, in other words, as the animate presence of “being lacking.” It is an ethnocentric caricature of “prescientific genius” supporting the *mytheme* of the *bricoleur* and not a depiction of the empirical reality or the truth of the situation. With the deconstruction of the phonocentric normativity of the laws governing the intersubjective violence of the unspeakable trace of the writing of the Other, the possibility, the hope, through which we can and must learn to reflect upon the ethnicity of our own thinking and practices of representation is situated in the in(deter)minable unfolding of *différance*.

Derrida elaborates a grammatological overhauling of semiology to rethink the differential and deferred relations of the iterativity of the sign, its spatiotemporal imprint, and the excesses of which manifest themselves in an alterity that the teleological perspective of an “ego-logical” philosophizing cannot comprehend or care to admit. The irreducibility of *différance* “shows up” the infinite exteriority of the arche-trace of

the Other through the *symploke*, or a weaving together of the diverse strands, of deconstruction, e.g., the yoking of undecidability with the heterology of its transcendental preconditions. The “unthought” difference between identity and difference, which is the exteriority of writing, hinges the turning point of the reversal and then displacement of the nature/culture dichotomy of metaphysics, the primary pragmatico-epistemic focus of its teaching we have been concerned with. Exposing how the teleo-phone of the logos is postponed in the self-irradiating trace of the fullness of presence, *différance* complicates the desire of the archive madness of the ancient thinking of the West that does not grant standing to the idea of the Other, its infusing in the idea of perpetuity, stasis, and fixed order the semblance of an outside, exteriority, to a pedagogy of the Same. Deconstruction contends, Derrida says:

... as always, [with] the institution of limits declared to be insurmountable, whether they involve family or state law, the relations between the secret and the non-secret, or, and this is not the same thing, between the private and the public, whether they involve property or access rights, publication or reproduction rights, whether they involve classification and putting into order: What comes under theory or under private correspondence, for example? What comes under system? under biography or autobiography? under personal or intellectual anamnesis? In works said to be theoretical, what is worthy of this name and what is not? (Derrida 1996)

We would include with this proliferation of questions the need to address the consequences of theory for the “topo-nomological” archive of the educational institution and the classification of knowledge in accordance with the historicity of the sign, and the means of consignment, the construction of a gathering place of domiciliation before and after the letter (see *ibid*). A deconstruction of the normative rendering of what it means to think, to learn, to teach, and to know begins to take root in the earliest of Derrida’s “texts” before *Of Grammatology*, where the nonnatural ethics of speech informing the socio-theologico-philosophical violence of metaphysics are put into doubt. It would not be hyperbole to suggest that from the start this

poststructural, post-phenomenological mode of intervention plays upon the thematic variability of the most fundamental and essential versions of the educational problematic of supplementarity discerning the continual transitivity of the human subject, for example, the heterogeneity of origins and the paradoxes of mimetology, childhood, reason, subjectivity, and so on as problems of mediacy and mediation. In short, it is the non-ground between presence and absence deconstruction “breaks into,” slowly making it possible to imaginatively empathize or “fill up” the openness of the abyss of this excluded space, the space of the writing/teaching of the Other, to reapproach the responsibility of the horizon of intersubjective violence and the ethnocentric teleologicality of the cultural politics of the sign.

In taking the pedagogical impetus of the grammatological reevaluation of the ethnocentrism of the sign further afield to the Hegelian era of speculative dialectics and the Absolute Idea, Derrida has pondered the birth and death of the philosopher and, thus, the thinking and teaching of the child through life that he considers to be associated with the themes of writing and memory. (This is evident in Jacques Derrida, *Dissemination*.) In *Glas*, we read a quite startling answer to a familiar, but difficult, question:

What is education? The death of the parents, the formation of the child's consciousness, the *Aufhebung* of its consciousness in(to) the form of ideality. (Derrida 1986a)

Using this quotation as a heuristic tool to approach some final comments on the question of the contradiction, Derrida finds in the proposal for a speculative didactics of infinitizing and hyperstatic memory G. W. F. Hegel lays out for a solicited “report” on philosophy curricula which would seem to be appropriate and somewhat precarious at the same time. But, nevertheless, for us, it will have already been necessary, if not essential, given its direct relation to any consideration of the topic of deconstruction and pedagogy at hand. The ideological symmetry between the text and the context of the report Derrida puts into question reinforces the need for the autobiographical projection of the image of the child,

before the end of philosophy and after the beginning of schooling, that Hegel submits to an eager State ministry ready to support an “instruction of memory.” A questioning and critical consciousness is not what a good citizen always makes from the perspective of the powers-that-be. And yet, the symbolic death here is not only of the parents but the decrease of their ability to have influence over the thinking of their dependent and powerless offspring. It is also the passing away of “the child” as such, a being of “non-knowledge” whose rebirth is achieved by the Hegelian propaedeutic through the retranslation or return of the essence of subjective formativity to a safekeeping of the “mobility” of consciousness within the bounds of the dialectical sublation of the idealizing moment of absolute insight or the Idea of Reason, the faculty represented most by the eternal logic and “Right” of the State. For Derrida, the fundamental problem is that of the acceptability of such provocatively generalizing recollections put forward as the result of a self-fulfilling prophecy of a vision of the truth of a past connected to a present/future that is all too removed from a time of reflection far gone and well lost. Because the auto-affective nature of the image of the pre-philosophical “child Hegel” cannot but regather the presence of the sign of the Self toward an inwardly reflecting point of imaginative centration reconciling elements of fact with those of fiction to comprise the temporal bridge between the “then” and the “now,” to resurrect in the annals of memory the gathering power of an ideal re-creativity is to more or less pursue the path to the teaching of false example, an exemplary teaching of falsehood coveting a *prosopopoeia* of the wishful apostrophe. So, the difference of consciousness and self-consciousness builds the symptomatic tensions of a hidden economy of loss that becomes evident in the rewriting of anamnesis after the deconstructive rereading of the report Hegel signs. The problematic synthesis of these antinomies of the *relève* of subjective identity comments on the theoretical validity of the example of the unsupplemented age of childhood, where the speculative schematism connecting empirical being to its “past being” – a being past (*Gewesenheit*) – is framed

according to the productive representation of a dialectical modality of circularly coherent reflexivity closed unto the reason of itself. The exteriorization of memory, its removal from the interiority of self-absorbing thought, “stays with traces, in order to ‘preserve’ them, but traces of a past that has never been present, traces which themselves never occupy the form of presence and always remain, as it were, to come – come from the future, from the to come” (Derrida 1986b). And the signature of the proper name of Hegel as a life writing of “the Self,” in this sense of the autogenetic reproduction of the metaphorical singularity of subjective identity, is an attempt to secure control over the hermeneutic effects of the aftermath of the ends of inscription by concretizing in the otherwise plain and customary mark of referential authority the pedagogical truth of the figure of the child prior to the experience of philosophy and the difficulty of thinking. Its belatedly teleologizing function of identifying difference that serves to “fill in the spaces” of the sociocultural puzzle of the categorical status of beings is a symbolic sanctioning of the logic to institute and implement a speculative curriculum of rote memorization for the teaching and learning of philosophy. The Hegelian model of pedagogy so defined within the possibility of the repeatability of the proper name, as such, is a progression of delay and derivation following the semantic after-effect of the originating source of the truth of the sign. And the time lag of its already-not-yet (*déjà-pas-encore*) structure authenticates the pragmatic working out of the educational configuration of speculative dialectics by sustaining, in its formal processes of dictation and memorization, the means to a looking back toward the generation of a “first” and “correct” meaning of a signifier to confirm its accuracy through the unmediated transmissibility of its proof. It should be clear considering what we have stated about the ethics of deconstruction up to now that Derrida could not support a mnemotechnical pedagogy favoring the passing of knowledge from the “expert teacher” to the “obedient student” or an institution that encourages the (re)playing and perpetuation of these monodimensional roles. Having become important as the interactive site

of competing interests and differential forces, the scene of teaching is the territorial mainstay of the political struggle its participants wage for the right of opportunity to intervene in the planning or actualization of curricular possibilities. Derrida, it would seem from reflections made about the commitment of his involvement with the GREPH (since 1974) (see Jacques Derrida, “The Time of a Thesis.”), has taken this activist role very seriously for the sake of saving the discipline of philosophy from those elected powers that have considered it an esoteric and dangerous subject, a part of the French educational system not worth the trouble of dealing with or keeping at bay, to the point where it was decided not to write a “thesis” because:

...it was neither consistent nor desirable to be a candidate for any new academic title or responsibility. Not consistent given the work of political criticism in which [he] was participating, not desirable with regard to a little forum that was more internal, more private and upon which, through a whole endless scenography of symbols, representations, phantasies, traps and strategies, a self-image recounts all sorts of interminable and incredible stories to itself. (Derrida, “The Time of a Thesis,” p. 48)

A dissertation would most certainly have been a chance to secure an eminent position suitable for a scholar of such international stature. Indeed, it was the reason Derrida was persuaded to submit his candidacy for a doctorate based on published texts, as he was encouraged to do so in order to be elected to the Collège de France, in succession of Paul Ricœur. The chair was eventually suppressed by the Ministry of Education. And those colleagues who had extended to Derrida the “invitation” to apply for the post eventually voted against him and he was given another position, the one he currently holds, on certain conditions). But as regards the type of interference, deconstruction can provide to alter the onto-encyclopedic reason of the educational institution to make its charity more equitable to acknowledging and accepting the logic of the Other; Derrida has never promoted the general dismantling of the architectonics of the pedagogical system. Rather, the focus of attention has been on finding a more “neutral” and less contentious site from which to

interrogate the axiomatics of the apparatuses of teaching and learning, one that effaces the tensions of the historico-political codification of the academic/bureaucratic dualism tranquilizing the cooperative processes of reflective transformation. Derrida explains:

It is this complementarity, this configuration [“often scarcely readable, but solid, between the most immobilized, contracted academicism and all that, outside the school and the university, in the mode of representation and spectacle, taps almost immediately into the channels of the greatest receivability” (Derrida 1979)]—everywhere that it appears—that we must, it seems to me, combat. Combat simultaneously, and joyously, without accusation, without trial, without nostalgia, with an intractable gaiety. Without nostalgia for more discreet forms, sometimes (sometimes only) more distinguished, less noisy, that in large part will yesterday have prepared the way for what we inherit today. (Ibid., p. 43. Derrida here explains what deconstruction ought to inspire in remarks made to the *États Généraux de la Philosophie*, a meeting of approximately twelve hundred participants who congregated at the Sorbonne on June 16–17 of 1979 to find common ground through which to combat the deteriorating situation of the discipline of Philosophy)

Deconstruction has been misrepresented by many critics, theorists, and philosophers unable or unwilling to take an account of and provide an accounting for its ethical and political implications, preferring instead to eschew or disregard both its effectivity in responsabilizing the principles of action and its informing of the reason of pragmatic utility. Attenuating the thematic scope of the analysis on the Derridean call to rethink the grounds of academic responsibility, e.g., the motivational imperative to respond according to a principle of “Right,” any reading of deconstruction in relation to educational philosophy must attend to the *aporia* of what is beyond the rationality of the institution of the university. There is a bridge to be built between the double-sided precipice of deconstruction, on the one hand, and the self-effacing void of metaphysics, on the other. This, of course, involves the question of responsibility and what is “proper” and “right,” of “the law” and “the political”: not to raise fears about the unjustifiable eradication of the university, an institution old and dear, as ancient as philosophy itself, a traditional knowledge structure, which is

very much in need of painstaking reconstitution, but to allay them in the well-meaning desire to rejuvenate serious exchange on the reason for its being. What Derrida does through deconstruction is to set up the positive parameters within which we can discourse on the subject ethically without barriers or boundaries, though not without obligation and the danger of failure. “The Principle of Reason: The University in the Eyes of its Pupils” shows how its discourse works on the figural play of the tropic framework circumscribing the living and metaphorical dimensions of these negative perimeters to broach the educational question of foundation and of ground, of principle and of law, and of departure and destination. Essentially, by relating the foci of these complementary pairings Derrida introduces – that are very different and yet also thematical the same – to the topological formativity of the structure of the institution itself, it has been possible to reread the ethico-political undertext of this instance of deconstruction through the metaphorical register of the text on the theme of the historicity of reason. We cannot dismiss, in this case, the use of the example of Cornell University, with its bridges stretching the campus across an abyss, as the living symbol or animate example of the parable being retold while its speaker is taking the first steps through the ordeal of this inaugural lecture toward the expressing of gratitude, returning its gift-counter-gift for the honor of being selected to a prestigious appointment. The specific conditions of the discourse – demanding a specific type of rhetorical demeanor appealing to an axiology of symbolic exchanges – generate the opportunity Derrida takes to comment on the interstices of text-context relations that construct the epistemic and empirical values of the constative and performative aspects of the academic responsibility Derrida culls after the “double science” of deconstruction. And this, more, than less, translates the emphatic urgency of the topic or theme of this lecture and the timeliness of its message for a sustained reappraisal of the ethics of academic responsibility patterned after the principle of reason. What Derrida shows is that there is no overcoming (*Überwindung*) of the technophilosophical grounding of intellectual freedom

or action within the speculum of an all-seeing, all-knowing university, the otoscopic-biographic sensibility of an instrumental and poietic landscape of the idea of the modern mind. And deconstruction does not – it cannot – claim to “come down” upon the reason of the institution with a full-forced vengeance in search of justice for it has no grudge to vindicate and no end to finagle and it is not outside the law. But this is not altogether true. It is outside the law. Rather, Derrida would say, and he has:

Deconstruction is justice. It is perhaps because law (*droit*) (which I will consistently try to distinguish from justice) is constructible, in a sense that goes beyond the opposition between convention and nature, it is perhaps insofar as it goes beyond this opposition that it is constructible and so deconstructible and, what's more, that it makes deconstruction possible, or at least the practice of a deconstruction that, fundamentally, always proceeds to questions of *droit* and to the subject of *droit*. (1) The deconstructibility of law (*droit*), of legality, legitimacy or legitimation (for example) makes deconstruction possible. (2) The undeconstructibility of justice also makes deconstruction possible, indeed inseparable from it. (3) The result: deconstruction takes place in the interval that separates the undeconstructibility of justice from the deconstructibility of *droit* (authority, legitimacy, and so on). It is possible as an experience of the impossible, there where, even if it does not exist (or does not yet exist, or never does exist), there is justice. (Derrida 1992)

The “real-as-absent” ground deconstruction covers, on both sides, as it were, how one should not speak of the university and the situation of its repositioning of ethics toward the possibility and impossibility of justice, that is, the undecidable responsibility symptomatic of the irreducible difference of an academic community in extension. This “double-edged” programmatology Derrida endorses, a metacontextual metadiscursivity critical of the sign of reason embedded within and exemplified by the regulatory principles of the institution, does not refer to a predestined plan of action, demands no disciples or followers, and concedes to the direction of no political program. Instead, it invites interpretation and invention that will produce a performative intelligibility or an inkling of purpose “yet-to-come” (*avenir*) out of the non-projection of a justification. The

notion is terrifying for some and self-mockingly illogical for others, especially concerning issues of institutionalized practice and pedagogical or techno-scientific, for example, and other research areas we have delineated pertaining to the disciplinary system of the university. But considering the outcome of reason once rendered for a future action is a moment of insurance or assurance already finite and past, there is no immanence of aspirations left other than a feigning of presence suffered as a remote controlling of praxis toward the unconditionality of what is the certainty of a non-end, the non-end of certainty.

To end, I would like to cite Derrida himself, for what he has admitted with respect to the risk and necessity of his own educational journey of/through deconstruction as a curiously convoluted and arduous path that eventually lead him to his post of Directeur d'Études: Institutions de Philosophie which traces the openings of deconstruction unto the horizons of the future and the possibility of an authentic pedagogy without boundaries or margins. When asked by Jean Hyppolite to explain the direction of his thinking, Derrida replied, “If I clearly saw ahead of time where I was going, I really don't believe that I should take another step to get there” (Derrida, “The Time of a Thesis,” p. 36). I will leave you to fill in the rest.

Derrida: Language, Text, and Possibilities

Richard Smith
Durham University, Durham, UK

The documentary film *Derrida* (Dick and Kofman 2002) opens with camera shots of the waters of the river Seine in Paris, traffic on flyovers and bridges, cement mixers and industrial cranes, and the backs of apartment blocks. Over these shots Derrida tells us that he makes a distinction between the future and *l'avenir*, the “to come.” The future is “tomorrow, later, and the next century”: it is foreseeable and predictable. It is part of the ordinary, even mundane, dimension of things that the camera has shown us. We know that there will be a tomorrow or the year 2050, even if we do not know what will occur then. To think of *l'avenir*, on the other hand, is to imagine the arrival of something or somebody radically unpredictable and unexpected, the coming of the wholly Other. This sense of a Beyond, of what transcends conventional knowledge and prediction, is the sense of a kind of specter: of what is not real in any common or usual meaning of the word but is powerful enough “to haunt us with uncanny possibilities, above all, the haunting possibility of the impossible” (Caputo 1997).

The writings of Jacques Derrida (1930–2004) are haunted by this possibility of the impossible. Later in the film, he talks about the impossibility of real forgiveness. Often when we say we forgive someone, it is more a way of trying to rid ourselves of our anger and resentment, or perhaps it is, consciously or not, a strategic move to put someone who has done us harm at a disadvantage. Something would have to be unforgivable in these false ways of forgiving if it could be the possibility of our truly forgiving it. Derrida embraces the paradox: we can only (only *really*, we might say) forgive the unforgivable. Elsewhere Derrida writes in similar terms of giving and the gift (*The Gift of Death*, 1995) and of hospitality (*Of Hospitality*, 2000). Most of our giving is colored by barely suppressed thoughts of reciprocity: what shall I give her for her birthday, bearing in mind what she gave me for mine? How good a bottle of wine should we take to their dinner party, in view of what they brought to ours? This is not the true making of a gift, since it involves calculation that is essentially focused on self-interest and avoiding embarrassment. Real hospitality in turn could not occur if our guests have power over us: we would be acting not out of hospitality but out of obligation. In fact hospitality seems to imply that we have some power over them: the power to offer food and shelter, say, or to refuse it. Yet this turns “hospitality” into an act of condescension, as it were to refugees whom we might as easily turn away from our door as admit through it. And this is not what we supposed we had in mind when we thought of hospitality.

This is to introduce some common themes in Derrida’s writings. At their heart is the constant reminder that concepts we normally treat as stable and take for granted may be far from fixed or secure and that the attempt to fix them tends to distort them and sell them short. There is a paradox here and Derrida’s readiness to relish paradox rather than resolve it. There is a hint of mysticism, most obviously in openness to the Beyond or *l'avenir*, to what cannot be known or named. At the same time, we might remind ourselves that some of these ideas are quite familiar to us and have a good deal of practical relevance. We might, for instance, worry about the way that schools and

universities these days are more and more being regarded primarily as places where young people acquire qualifications that will help them find jobs. What has become of them as essentially places where education, and not just preparation for examinations, takes place? Yet the project of making a university a distinctively and fully educational place is not like the project of traveling to Tokyo or climbing a particular mountain. The latter can be ticked off our list of things done, but there could never be a point where we sat back, satisfied that we had built the university of our educational dreams. This will always lie beyond anything that the most enlightened reforms could bring about.

I will return to these points later. Something must be said first, however, about the paradoxical nature of this chapter itself. I hope to explain some of Derrida's principal ideas as clearly as I can: to place them firmly for the reader, so to speak. Thus I risk fixing, as if they were doctrines, the complex thought of a writer who is the least doctrinaire of all, who asks us to get over our habit of trying to fix, to nail down, what is by its nature fluid, slippery, labile, protean. I can only acknowledge the contradiction. There are various ways around it, including attempts to imitate Derrida's elusive and complex prose style – attempts that do no service to the reader who is, reasonably, hoping for a readable introduction. Perhaps I may at least observe that this chapter is hardly intended to be the last word on the subject and this not just in the spirit of proper diffidence but because the concept of a "last word" is peculiarly inappropriate to any text that takes Derrida as its subject.

Jacques Derrida is usually described as a "post-structuralist." This is to trace a significant line of intellectual descent from the Swiss linguist Ferdinand de Saussure (1857–1913), who is generally thought of as the founder of structuralism. Saussure was interested in just how language has meaning. It is natural to think that the meaning of a word is given by what it labels: the meaning of "table" is given by the physical object, in this case the table on which my laptop rests. This is often called the Augustinian picture of language, after some remarks by St. Augustine in his autobiography:

When grown-ups named some object, perhaps gesturing towards it, I noticed it and grasped that the object was named by the sound they made when they deliberately called it to my attention . . . Thus I gradually realised what objects were signified by the words I heard when they were regularly used appropriately in various sentences. (*Confessions* I. 8, my translation)

Wittgenstein quotes a slightly longer version of this passage at the very beginning of his *Philosophical Investigations* (1972). He comments that Augustine gives us here a "particular picture" of the essential nature of human language. In this picture "the individual words in language name objects – sentences are combinations of such names." Thus the general idea is that "Every word has a meaning. This meaning is correlated with the word. It is the object for which the word stands" (§ 1). Wittgenstein, Saussure, and Derrida all find the Augustinian picture inadequate. Wittgenstein notes that often language does not so much refer to or picture reality as constitute it. For instance, to say to someone "I promise to pay this money back to you next week" is not to refer to something but to do something, that is, to promise. The same is true when we ask someone to pass the salt, invite them to a party, warn them about the patch of ice ahead, or apologize for standing in their way. None of these uses of language label, refer to, or picture reality: they perform an action. They are sometimes called "performative" uses of language.

For a structuralist like Saussure, the crucial point is that while it is natural to think that the meaning of "laptop" or "refrigerator" is given by the object which the word labels, the same does not apply to an extensive range of other words such as "and," "the," "nevertheless," or "Sunday." If in one of my lectures I ask the students what "laptop" means, they will very reasonably point to the object in front of them and say "It's one of these." They have difficulty on the other hand in finding howevers or Sundays that they can point to. Saussure tells us not only that language does not always mirror the world but also that in general language has meaning via relations of difference. Language is a system of signs and of differences. The meaning of "man" lies in its differentiation from "woman." "Sunday" has

meaning by virtue of being neither Saturday nor Monday nor any other day of the week. There is no such thing as a Sunday for it to reflect and derive its meaning from.

Furthermore, the connection between words and what we think of them as naming is arbitrary. We might like to think of the word “Sunday” as distilling the essence of that particular day of the week (going to church, watching a football match, spending time in the garden, eating an unusually large lunch), but “Sunday” has no inner Sundayness to which it can refer, not least because millions of people spend their Sundays without doing any of these things. We might like to think of the word “rose” as somehow capturing the very nature of that beautiful and scented flower but, to quote Shakespeare, “That which we call a rose / By any other name would smell as sweet” (*Romeo and Juliet* II. ii 1–2). We like to think that some words at least display that essential relation in the form of onomatopoeia: we represent a dog’s bark as “woof woof” because that is, as a matter of fact it might seem, the sound that a dog makes. While in Britain dogs say “woof woof,” however, in France they say “ouah ouah,” and in China “mung mung.” Or we might like to imagine there is some other kind of intrinsic relationship between a word and what it indicates. We write “giraffe” on the board and, for the children’s benefit, we turn the two letters “f” into tall animals side by side. Look, children! And the very word “look” – doesn’t it seem to have two eyes at its center? We can write that on the board as well, and dots in each letter “o” make everything clear.

The central feature of poststructuralism is that it takes Saussure’s ideas much further. For Derrida meaning is not just arbitrary: it is unstable. This too is a feature of language that should be familiar enough to us. The word “wicked” supplies a good current example; where it once simply indicated a high degree of nastiness or evil, it is now often used for emphasis, as an alternative to “really” or “very”: the online Urban Dictionary offers as an example “This car is wicked cool.” The word “fit” is at present in the process of shifting from its old meaning of “in good physical condition” to its new sense of “sexually attractive.” The instability of language can be illustrated by further examples.

What is the meaning of “Stalin”? Does it denote a great leader who saved Europe from the tyranny of fascism or a psychopathic, paranoid dictator who was responsible for the deaths of millions of his fellow Soviet citizens? What are we to make of the French Revolution of the late eighteenth century, which brought to France greater social equality but also the “Reign of Terror” in which tens of thousands of innocent people were murdered?

Thus the full and final meaning of a word or a text is never conclusively reached. Caputo (1997), in the best discussion of Derrida that I know, notes that the very idea of letters, of rereading, opposes closing things down. He writes that “the letter, by its very structure, is repeatable, disseminative, public, uncontainable, unfettered to any *fixed* meaning, destination or context” (p. 59). There are some kinds of writing where this is clearly the case. A play by Shakespeare – *Hamlet*, say – is constantly being interpreted and reinterpreted. There are interpretations that offer a feminist reading, for example, or a Freudian one, and naturally there are poststructuralist readings. Every generation comes to the play with new interests and perspectives, and being a rich and complex text, there will always be new interpretations (and interpretations of these interpretations, as when we reevaluate the work of a particular literary critic). The process is endless, and it makes no sense to suppose that 1 day we shall reach the correct and ultimate interpretation, after which all further work on the play can cease. Not even the writer of the play (or poem or novel) can be authoritative about the meaning of her text. There is no anterior meaning which Keats grasped in its entirety before embodying it in a poem. Otherwise a plain statement of the meaning would be as good as, or perhaps better than, the poem itself. (This is not to say that every interpretation is as good as every other: some may be rich and productive and others crude and sterile.) The meaning of Keats’s poem, or of *Hamlet* or of every text, is thus deferred, as Derrida puts it. The ideal interpretation is always to come.

The instability of language is further emphasized by Derrida’s treatment of binary thinking. When we note differences between two terms, we

are inclined to think of one of the pair – of the binary – as somehow superior to the other. “Man” is different from “woman,” but it is easy to slip into the assumption that man is not just different but superior here. The phrase “the history of mankind,” for instance, suggests that any history worth writing will be the history of the lives and deeds of men, not of women. The talk of “manning the fire engine” implies that women cannot be firefighters (whom in Britain we have only recently stopped calling “firemen”). Consider other binaries: reality/appearance, presence/absence, adult/child, and literal/metaphorical. We readily conceive the first term as prior and the second as derivative or secondary. Derrida offers us readings of texts where, at the touch of a careful reading, these binaries turn through a hundred and eighty degrees or fall apart altogether. These readings are the kind of criticism that he calls “deconstruction.”

Derrida (1981) offers an example of deconstruction in a reading of Plato’s *Phaedrus*. Plato’s text is written as a dialogue between Socrates and the young man, Phaedrus, from which it takes its name. Here, in the very form of the text, is the assumption of the supremacy of speech over writing (another binary: speech/writing). It is easy to imagine that the spoken (and heard) word is somehow prior to the written word and that writing is an attempt (necessarily inadequate: how, for example, could it catch the speaker’s exact tone?) to capture its immediacy. Speech, Socrates tells Phaedrus, bears a closer relation to thought than writing. When you write something down, you often have a sense of “that’s not what I meant to say”; you cannot question writing in the way that you can ask a speaker what he meant. And of course this is why the *Phaedrus* is written, as virtually all of Plato’s texts are, as a dialogue. But it is *written* as a dialogue, as Plato would hardly not have noticed. It is full of literary tropes: metaphor, figurative language, and rhetorical devices. At the point where we thought we were establishing the supremacy of speech over writing, the writing that appeared to be persuading us of the strength of the case shows the precise opposite. The speech/writing binary is turned, dizzyingly, upside down.

Derrida coins the word *différance* to capture the nature of language both as a system of differences and as the endless deferral of meaning. The French verb *différer* means both to differ and to defer, and the noun derived from it is *différence*, spelled with an *e*. By spelling the new word with an *a*, Derrida not only highlights the two meanings of *différer* but plays something of a joke. In our binary thinking, we give speech priority over writing, but the difference between *différance* and *difference* can only be registered in writing: the two words sound exactly the same in speech. Thus again the speech/writing binary is problematized, since the normal order of priority is inverted: only in writing, and not in speech, is justice done to the nature of language.

These ideas are disconcerting, especially in the face of the widespread desire to find something secure and reliable to guarantee the meaning of language and put an end to the disseminating play of signifiers. Derrida calls this desire for something indubitably *there* behind the language the “metaphysics of presence.” The phrase recalls Descartes, who hoped to base certain knowledge of indubitable truths in his own presence: in thinking and doubting, at least he could be sure that he was real. In another of its forms, the desire appears in the appeal to reality, as when people are told that their academic qualifications will not impress anybody in “the real world.” In another, “what works” is called on to do the job, as when it is proclaimed that the only educational research worth the name is the kind that reveals “what works” in the classroom: as if what counts as “working” (short term or long term? Resulting in next week’s test scores or the development of deep understanding?) was not itself contestable. Divine sponsorship is sometimes seen as the answer: “In the beginning was the Word, and the Word was with God, and the Word was God” (John 1. 1, Authorized Version). This is a natural temptation for Muslims, Jews, and Christians, who variously regard themselves or each other as People of the Book, of the text of the Qur’an, Torah, or Bible. Whether turning from words to the Book and the Word demonstrates a fine consistency or a deep irony is beyond the scope of this chapter.

Derrida writes that interpreting text takes place in “the absence of the referent or the transcendental signified,” that is, something secure that refers to what language refers to or goes beyond it. Reading, in one of his most well-known formulations,

cannot legitimately transgress the text toward something other than it, toward a referent (a reality that is metaphysical, historical, psychobiographical, etc.) or toward a signified outside the text whose content could take place, could have taken place outside of language, that is to say, in the sense that we give here to that word, outside of writing in general ... There is no outside-text. Derrida (1997/1967), p. 158.

The phrase translated above as “there is no outside-text” is *il n’y a pas de hors-texte*. This is sometimes mistranslated as “there is nothing outside of text,” as if Derrida was, absurdly, claiming that nothing existed but text. We might rather use the analogy of a Möbius strip, which is made by giving a strip of paper a half-twist and joining the ends together so that the strip forms a continuous loop. If we think of one side as being for writing, there is no other side for anything else. Derrida is criticizing “the tranquil assurance that leaps over the text toward its presumed content, in the direction of the pure signified” (*ibid.*, p. 159).

That assurance, it should be noted, whether tranquil or not, is much in evidence in our own time. It is displayed by the numerous attempts to fix the meaning, to declare that there is one true meaning and no other. There is space for only one example. UK universities are now the responsibility of the Department of Business, Innovation and Skills, and its official publications hammer home the message that the purpose of going to university is simply to become the kind of graduate that “employers want” (this phrase occurs 35 times in a recent government document: see Collini 2016), as if no other possibilities and no different ideas of the university had ever been entertained. The search for secure foundations leads to fixed fundamentals, and from there the road leads to Fundamentalisms of all kinds, not least the neoliberalism that currently claims to speak the one true language of the real world. Derrida shows us that we do not have to take this road.

Derrida's Deconstruction Contra Habermas's Communicative Reason

Rauno Huttunen

University of Turku, Turku, Finland

University of Joensuu, Joensuu, Finland

Introduction

In 1985, Jürgen Habermas (1929–) published a number of very critical comments on Jacques Derrida (1930–2004) in his book *The Philosophical Discourse of Modernity*. Derrida reacted by saying that Habermas had either misread him or perhaps not even read him at all. In 1988, Derrida replied briefly yet informatively in an interview published by Autrement 102 (Derrida 2006), after which both parties remained silent until the end of the 1990s. (Derrida also wrote two lengthy footnotes in the 2nd English edition of *Memoires for Paul de Man*, note 44 and, in *Limited Inc*, note 9. See Derrida 1988, 1989.) It was then that Derrida and Habermas met at a party and Habermas proposed a friendly discussion. Derrida and Habermas actually set aside their differences and concentrated on themes upon which they both agreed. Before Derrida died, they jointly published one book and several articles.

In spite of temporarily finding common ground, Habermas and Derrida never did achieve a common understanding on the nature of modernity and the relationship between “rational reconstruction” and deconstruction. Habermas never did really understand the idea of deconstruction and considered it irrational and antimodern. Derrida intentionally misunderstood Habermas's reconstruction of the speech act theory, which presupposes that “misunderstanding” and the strategic use of language are abnormal situations in linguistic interaction. This reciprocal misunderstanding between Habermas and Derrida is actually a good thing for those interested in philosophizing on the tension between deconstruction and communicative rationality and the consequences of that tension for the educational science and education. How should education as a science and a practice – which is a product of Enlightenment – understand Derrida's demand for deconstruction? What kind of education is possible after destruction? Or should education rely solely on Habermasian communicative reason as a reconstructed version of Enlightenment?

Jürgen Habermas

Jürgen Habermas is without no doubt the greatest living German philosopher and he has become famous because of his grand theory called the communicative theory of action. At the heart of Habermas's theory of communicative action is the vision that the modern worldview is differentiated into three parts. Following Immanuel Kant and Karl Popper, Habermas distinguishes the objective world, the social world, and the subjective world. A communicatively competent speaker can independently present differentiated statements concerning any of these three worlds. She can independently evaluate any statement about the world with proper validity claims. There are three validity claims for these three worlds:

1. Truth (*Wahrheit*). A claim that refers to the objective world is valid if it is true, i.e., if it corresponds to the reality.

2. Truthfulness (*Wahrhaftigkeit*). A claim that refers to the subjective world is valid if it is honest, i.e., if it has an authentic relationship with the subjective world.
3. Rightness (*Richtigkeit*). A claim that refers to the social world is valid if it does not contradict commonly agreed social norms (Habermas 1984, p. 440).

Let us examine the example of the claim “Teachers have right to practise indoctrination in schools.” This validity claim is refers to the social world, and its proper validity claim is rightness (justice). A communicatively competent opponent could challenge this validity claim is by stating that it contradicts that which is commonly considered as morally correct behavior (or it would be commonly considered as such in a free and critical discourse). If an opponent merely says that “My inner self told me that indoctrination is wrong” (truthfulness or authenticity) or “It is scientifically proven that indoctrination is wrong” (truth), she is using an incorrect validity claim and she is not a communicatively competent speaker. So, in this case, the proper validity claim is that of rightness or justice.

Habermas theory of language is connected to his division of human action. Habermas divides ideal (pure) types of action into the categories of social and nonsocial action. An object of nonsocial action is nature, and the objects of social action are other people. According to Habermas, nonsocial action is always purposive-rational instrumental action: the actor makes use of specific objects for his or her own benefit. Social action can be either success-oriented strategic action or understanding-oriented communicative action. Strategic action is purposive-rational action oriented towards other persons from a utilitarian point of view. The actor does not treat others as genuine persons, rather as natural objects. Strategic action means calculative exploitation, or manipulation, of others. An actor who acts strategically is primarily seeking her own ends and manipulates other people either openly or tacitly. Communicative action is the opposite of strategic action. Communicative action – or its pure type – means interpersonal communication, which is oriented towards mutual understanding

Derrida’s Deconstruction Contra Habermas’s Communicative Reason, Table 1 Pure types of action (Habermas 1984, p. 285)

		Action orientation	
		Oriented to Success	Oriented to reaching understanding
Action situation	Nonsocial	Instrumental action	–
Action situation	Social	Strategic action	Communicative action

and in which other participants are treated as genuine persons, not as objects of manipulation (Table 1). Actors do not primarily aim at attaining their own success but want to harmonize their plans of action with the other participants (Habermas 1984, p. 285; see also p. 333). Following Austin and Searle Habermas claims that the use of language with an orientation of understanding is the original mode of language use and strategic use of language is “parasitic” (Habermas 1984, p. 288).

Max Horkheimer and Theodor Adorno (1972), in their book *Dialectic of Enlightenment*, maintain that the rationalization of society means above all the growth and expansion of instrumental reason. Habermas’s view is more optimistic. He states that modernization promotes both strategic and communicative rationalization. Communicative rationalization means spreading of communicative reason and it is possible because of differentiation of the “worlds” and validity claims. Habermas puts high hopes to communicative rationalization. That is why Habermas is the heritor of Enlightenment and Enlightened Reason.
